**The Rochdale Pioneers.**—One of these branches, no. 24, formed in 1837, was in Rochdale. It was a very active branch, having its Social institution, holding lectures by prominent Owenites (including Owen himself), running a day school and an evening school, engaging in public debates with the rival Chartist movement on the subject of socialism versus Chartism and raising funds for the Queenwood community.

It was this group of Owenites who founded the Rochdale Society of Equitable Pioneers, 1844, generally regarded as the beginning of the modern co-operative movement. The leading figures and 16 of the original 28 Pioneers were members of this branch. Most were not weavers, although the defeat of a weavers' strike and the subsequent intention to start a weavers' productive society provided the opportunity for the Owenites to persuade the weavers to join them in establishing a society on similar lines and with the same objective as that advocated by King. They had studied King's writings and one of the leaders of the branch, James Smithies, had all the issues of *The Co-operator* bound in one volume.

From their rules and practices what came to be known as the Rochdale principles were culled. There are differences in the lists of these principles given by various writers because the original Pioneers did not draw up a statement of principles. The principles were: open, voluntary membership; democratic control; limited interest; dividend on purchases; education; trade only in pure goods; true weight and measure; religious and political neutrality. The society overcame initial difficulties, including the severe depression of 1847, and achieved such success that it came to be regarded as the model for other societies not only in Great Britain but in other parts of the world. G. J. Holyoake's *Self-Help by the People: History of Co-operation in Rochdale* (1858) was translated into many languages and made the Rochdale system known the world over.

The success of the society is often ascribed to the attraction of dividend on purchases, which provided quick and tangible benefits from co-operation. Although undoubtedly important, it was by no means the sole reason for success. Dividend was not regarded as the end or purpose of the society and there was a grasp and understanding of its social ideals which promoted loyalty and secured a ready adherence to its principles. The early members were enthusiasts for education. As Owenites the formation of human character was more important to them than trading, and they engaged in educational activities, using the society's premises and making grants for education even when these were illegal. They desired a rule allocating 10% of profits to be used for educational purposes, but the registrar would not agree to more than 2½%. A fine library with news room was acquired, classes were held and lectures given. The society was the principal educational body in the town for many years and was something of a

pioneer in adult education in conjunction with the universities.

Activities were not confined to the development of the society alone. In the first 25 years it assisted or took part in other co-operative enterprises in the town, e.g., a co-operative corn mill, a sick and burial society, a building society and a cotton-manufacturing society, and had the leading part in establishing the Co-operative Wholesale society and the Co-operative Insurance company. The place of the Rochdale Pioneers in co-operative history does not rest alone upon the famous Rochdale principles, for there was actually little that was original in these, but also upon their work in founding the movement. They were active in developing co-operation outside their own society; many retail societies were inspired and advised by the Rochdale men. They drew up and published model rules to guide societies, convened conferences on matters of general concern, pioneered co-operative wholesaling and supplied some of the great leaders of the national movement, notably Abraham Greenwood and J. T. W. Mitchell.

**The Christian Socialists.**—In the 1850s a group of professional men known as the Christian Socialists (*see* CHRISTIAN SOCIALISM) attempted to establish self-governing societies as a solution to the conflict between capital and labour. Their ventures failed but some of them, notably E. V. Neale, Thomas Hughes and J. M. Ludlow, were drawn into the co-operative movement and continued to play leading parts in it during the 19th century. They were instrumental in obtaining more satisfactory laws relating to co-operative societies, especially the Industrial and Provident Societies act (1852). Hughes and Neale wrote a *Manual for Co-operators* (1881). Neale suggested several fruitful ideas of national development and eventually became general secretary of the co-operative union; Ludlow became the chief registrar of friendly societies.

**National Organizations.**—The need for a co-operative wholesale organization had been realized in the 1850s and both the Rochdale group and Neale had made unsuccessful efforts to meet it. A change in the law which permitted societies to hold shares in each other's enterprises made possible a federal organization for the purpose, and in 1863 the North of England Wholesale Industrial and Provident society, later known as Co-operative Wholesale society (C.W.S.), was established. Only 50 of the 454 societies then existing joined it at first, the membership of the Rochdale Pioneers constituting about one-quarter of the aggregate membership of the societies first affiliated to the wholesale society. In 1868 Lloyd Jones and William Pare, both leading figures in the Owenite movement, were still active in the movement and desired to revive the Co-operative congress. Their efforts, together with the support of H. Pitman's *Co-operator* (1860-71), brought about the Co-operative congress in 1869, the first of a series. Out of these congresses was developed the Co-operative union, an organization open to all co-operative societies undertaking propaganda, educational, research and advisory work for them and representing them in dealings with the government and with trade unions.

During the 1870s the movement was shaken by the failure of a number of productive societies, mainly in textiles, coal mining and engineering. The C.W.S. had opened a banking department (1872) and commenced production in 1873. These steps were strongly opposed by Hughes and Neale and gave rise to great consumer-versus-producer debates in the 1870s and 1880s. Producer co-operation, however, revived in the 1880s partly because of recovery from the slump of the 1870s and of the efforts of the Co-operative Productive federation, set up in 1882. The trades entered were mainly printing, clothing and footwear. These had the advantage of co-operative markets and retail societies also invested in them. The strength of the case for producer co-operation was, however, largely destroyed by the publication of Beatrice Potter's (later Mrs. Sidney Webb) *The Co-operative Movement in Great Britain* (1891). She and Webb carried on a life-long attack on producers' co-operation and were strong and effective advocates of consumer co-operation.

The wholesale societies continued to extend their activities in the range of trade and production, uniting for joint enterprises in the English and Scottish Joint Co-operative Wholesale society

and the Co-operative Insurance society. Co-operative congresses generated various developments, among these being the formation of the North of England Co-operative Newspaper company (1870) which began to publish the *Co-operative News* in 1871, the oldest working-class newspaper in existence. Developments of the co-operative press continued, both in organization and in number and range of publications. The Co-operative union and the wholesale societies published books and periodicals, but the *Co-operative News*, *Scottish Co-operator* and *Reynolds News* (a Sunday paper) with various weeklies and quarterlies are published by the Co-operative Press, Ltd. This is an independent body, although its shareholders are co-operative societies.

Suggestions were made shortly after the passage of the Reform act (1867) that the co-operative movement should have some parliamentary representation, and efforts were made between 1892 and 1914 to persuade the Co-operative congresses to agree to take steps to that end and to form an alliance with the Labour party and the trade unions. These efforts were unsuccessful, until annoyance with government indifference to co-operative grievances during World War I resulted in a decision to seek political representation at a special congress in 1917. Resulting from this decision, the Co-operative party was formed and this found that, for practical purposes, an alliance with the Labour party was necessary. Agreements were made (1927, 1946, 1958) which made co-operative members of parliament and candidates subject to control by the Labour party. The Co-operative party, however, is subject to the Co-operative congress and is financed by the fees of societies affiliated to it. Societies are free to affiliate or not and every society affiliated with the Co-operative party has decided to do so by vote of its own members.

**Retail Society Developments.**—Steady although unspectacular growth was made by the consumer movement in the 20th century. Individual membership of retail societies more than doubled every 25 years between 1875 and 1950, and amounted to more than 12,500,000 in 1960. From 1938 to 1958 the volume of trade increased from £263,000,000 to £997,000,000, share and loan capital from £183,000,000 to £356,000,000 and reserves from £15,000,000 to £37,000,000. The greatest growth of membership occurred in the midlands and the south, although the northern parts of England and Scotland continued to grow faster in trade and capital per member. Co-operative growth after 1920 was also mainly in large towns and cities, in which it was generally weak before 1914. The combined membership of the metropolitan societies increased from 270,000 in 1920 to 2,148,000 in 1958. Societies also grew in size: whereas in 1920 no society had a membership of 100,000, in 1958 there were 18 such societies, with an aggregate membership amounting to 33% of the movement's total. In 1958 more than half the total membership was in societies with a membership of more than 50,000 each. Much of the increase in size was due to amalgamations which reduced the number of societies from 1,455 in 1903, 1,379 in 1920 to 918 in 1958. The increase in size presented problems of management, democratic control and the maintenance of the average member's interest and loyalty.

The general pattern of co-operative trade changed little: food-stuffs amounted to 75% of the total in 1958, almost the same proportion as in 1938. New methods of retailing were introduced and developed by co-operative societies in the 1940s and 1950s, mainly self-service shops, supermarkets and mobile shops. In 1950, 90% of self-service shops were co-operative and in 1958 there were still more co-operative self-service shops than any other (4,500 co-operative, 1,350 multiple, 550 other), and more than half the number of mobile shops were co-operative in 1957. The movement, however, was not engaged in mail-order trading or in that of the variety chain store. Although credit trading was common in co-operative societies before World War II, its trade was and is predominantly a cash trade: the proportion of members' indebtedness to its total trade in 1938 was 2.7%, in 1958 it was 2.5%.

The wholesale societies, dependent for capital, trade and directorial control upon the retail societies, have naturally a similar pattern of development. The business of the C.W.S. increased from £205,000,000 in 1946 to £463,000,000 in 1958, that of the

S.C.W.S. from £44,000,000 to £90,000,000. The C.W.S. was Britain's largest business in 1958, excepting some nationalized industries. It had more than 200 factories and farms, 50,000 employees, and depots in many parts of the world. It was one of the largest farmers, with farms and estates amounting to 34,000 ac., an agricultural department with a trade of £34,000,000 and agricultural co-operatives from which it bought large quantities of produce. Current account turnover of its banking department increased from £1,334,595,000 in 1946 to £5,042,323,000 in 1958, that of the S.C.W.S. from £102,925,000 to £507,963,000. The Co-operative Insurance society, a joint venture of the C.W.S. and the S.C.W.S., increased its premium income from £9,058,000 in 1938 to £47,702,000 in 1958. Exclusive of overseas workers, the co-operative movement employed 395,657 workers in 1958.

Co-operative workers' productive societies remained mainly engaged in the printing, clothing and footwear industries. As these did not enjoy the general expansion of the 1950s, they did not grow at the rate of the co-operative movement in general. But little advance was made generally by this type of co-operation during the 1920-60 period. The number of societies changed little during this time, 44 societies being affiliated to the Co-operative Productive federation in 1923, 46 in 1955 and 41 in 1958. The number of employees is a fair measure of their growth: there were 5,217 employees of these societies in 1923, 5,481 in 1955 and 4,898 in 1958.

**Organization.**—The co-operative movement is organized from the bottom upward. At the base are the individual members of the primary societies, in Great Britain mainly retail societies. Members are in no way subject to their societies but the societies are subject to the members, whose interests they exist to serve and to whom they are responsible. These societies associate in federal societies, local and national, yet the same relations exist. The federal societies exist to serve the purposes of the member societies, to whom they are responsible, but the member societies surrender none of their independence and are autonomous bodies. Each higher organization is created by and controlled by those below it, not by those above it. If there is any sovereign authority in the co-operative movement, it is to be found in the basic units, the individual members of the primary societies.

The principal national organizations are those mentioned above—the C.W.S., the S.C.W.S., the C.P.F., the Co-operative press, the Co-operative party and the Co-operative union. This latter includes most co-operative societies and is generally regarded as representing the co-operative movement as a whole. It is organized on sectional lines, Great Britain being divided into eight sections for the purpose and there is also an Irish section. Each section has a board elected by the societies in its section, which is concerned with the affairs of the movement in its section but which also expresses the voice of the section in national affairs and also exercises some control over them. The central executive of the Co-operative union consists of two representatives of each sectional board, except the Irish, which has one, and representatives of the C.W.S., the S.C.W.S., C.P.F., Co-operative press and Co-operative party. Sectional representatives number 17, those of the national organizations number 10. The central executive is responsible for managing the affairs of the Co-operative union and determining co-operative policy between congresses. Although the central executive is ultimately responsible for management and policy decisions it effects its work through four main subcommittees, General Purposes (concerned with finances and management of the C.U.), Parliamentary, National Policy and Economic. Each section is represented on the General Purposes committee which is the main committee, and so is each national organization with the exception of the Co-operative party. A similar pattern exists with other C.U. organizations: the National Wages board (which negotiates on a national level with the trade unions) has two representatives from each section and two from the central executive. The trade associations have generally one from each section and representatives of the central executive and the wholesale societies. By this organizational structure each sectional board and national organization is kept well informed of the conduct of all affairs by the Co-operative union and is able to voice its opin-

ions and share in control. A Co-operative congress is held annually, attended by delegates from all Co-operative union member societies. Its principal business is consideration of the report of the central executive, which is a statement of all the work of the Co-operative union in the preceding year. Resolutions on matters of the Co-operative union, on those of the retail societies, the national organizations and international questions are moved and discussed. But the only effective resolutions are those referring to the Co-operative union itself. Congress has no constitutional power over the individual societies or the national organizations excepting the Co-operative union and the Co-operative party. Nevertheless resolutions which refer to co-operative affairs have often given a lead and exercised considerable influence.

**Agricultural Co-operation.**—The agricultural societies have not been willing to enter into the main stream of the British co-operative movement, although most are members of the C.W.S. and relations are amicable. Circumstances and the inspiration and leadership of Sir Horace Plunkett (*q.v.*) enabled a successful agricultural co-operative movement to develop earlier and more rapidly in Ireland than in Great Britain. The English movement grew slowly and almost suffered catastrophe in 1924 with the collapse of the Agricultural Organization society (established 1901) and the Agricultural Wholesale society (established 1918), victims of the postwar slump. The C.W.S. did much to keep some of the societies alive, but although the National Farmers' union took the affairs of the movement into its hands, agricultural co-operation was handicapped by lack of zealous organization to further it. The formation of the Agricultural Co-operative Managers' association in 1936, the Agricultural Co-operative association in 1945 and the Agricultural Central Co-operative association in 1956 helped to remove this handicap. There are separate agricultural organizations in Wales and Scotland. During and after World War II, agricultural co-operation grew rapidly. Membership in England increased from 108,000 in 1946 to 230,687 in 1958, trade from £25,000,000 in 1946 to £129,189,000 in 1958. Requisite societies have always been and are the strongest, accounting for £80,000,000 of this turnover. (A. Bo.)

### UNITED STATES

Co-operatives in the United States may be classified by specific function as: (1) farmer-owned marketing, processing and purchasing associations; (2) retailer-owned wholesale co-operatives; (3) credit and banking co-operatives (including credit unions and the nationwide farm credit system); (4) mutual insurance companies; (5) rural electric co-operatives; (6) consumer goods stores; (7) group health and medical plans. In addition, there are co-operatives performing miscellaneous farm services (*e.g.*, artificial breeding, cotton-ginning), housing co-operatives, student co-operatives (dwellings, bookstores and other facilities), rural telephone co-operatives and burial associations.

The first seven types are listed in the approximate declining order of their annual business volume. Of an estimated annual total co-operative business of \$24,000,000,000, farmer-owned marketing, purchasing and service associations accounted for nearly half the dollar volume in the early 1960s.

**History.**—Co-operative endeavour in the United States was started by workers' groups. An early example was the establishment of a short-lived co-operative boot and shoe factory by the Journeymen Cordwainers' union of Baltimore, Md., in 1794. Two groups of workers launched co-operative stores in 1829, one in Philadelphia and the other in New York. Two years later, co-operative trading was discussed at the first annual convention of the New England Association of Farmers, Mechanics and other Workingmen, and co-operative stores were soon established. A member of this association took a leading part in organizing the Workingmen's Protective union, which sought to accomplish "broad social amelioration" through "cooperation, mercantile and fraternal." By 1857 membership in the union extended to the six New England states and New York. Distrust and dissatisfaction caused some members to break away and form the American Protective union in 1853, which did not share the social aims of the original union. Both agencies were weakened by internal

problems. They were also the targets of competing merchants, and suffered from the financial panic of 1857 and pre-Civil War economic dislocations. The majority of local stores disbanded without loss to their members; some distributed sizable accumulated earnings. Their experience illustrated elements of weakness and strength in co-operative endeavour.

The first recorded co-operative effort among farmers in the U.S. was a "dairy" (presumably a creamery) established at Goshen, Conn., in 1810. By 1867, there were over 400 co-operatives processing dairy products in the eastern United States. In 1820 a group of Welsh farmers at Granville, O., began marketing hogs co-operatively. Wool pools were established during the 1840s and Wisconsin grain farmers erected an elevator at Madison in 1857. Co-operative purchasing of farm supplies began on Long Island in 1863 with the formation of an association to buy fertilizer in wholesale lots.

Meanwhile the success of the Rochdale Pioneers in England in the middle of the 19th century (*see above*) was widely publicized. More than a century later, true co-operatives throughout the world still acknowledged and respected the Rochdale principles, regardless of their degree of adherence to them. Although they were promulgated for consumer co-operative stores, they were also applied to agricultural producers' co-operatives.

The founding of the National Grange in 1867 gave impetus to co-operative activity in the U.S. (*see GRANGE, THE*). A sponsor of "cooperation in all things," the Grange declared that its objective was to bring "producers and consumers, farmers and manufacturers, into the most direct and friendly relations possible." It grew slowly at first but later had 24,000 local organizations. It exerted political influence at the national level and emphasized economic activities locally. It established state and county agencies for marketing farm commodities, purchasing farm supplies, operating stores, manufacturing farm equipment, and for banking and insurance. Without co-ordination at the national level, the state and local operating methods were divergent and not conservative.

In 1874 the Grange sent a representative to England to study the Rochdale system and soon thereafter operating rules and directions for organizing co-operatives on Rochdale principles were developed and distributed by the National Grange headquarters. Although the Grange movement was largely spent by 1885, Grange-sponsored or Grange-organized co-operatives continued to function throughout the nation. In later decades, Farmers union and Farm Bureau organizations in many states encouraged and assisted in the formation of co-operatives—principally farmers' marketing and purchasing associations—some of which attained imposing size.

This glimpse of co-operative history reveals two streams of endeavour—one directed toward savings in cost of consumer goods, the other directed toward higher net farm incomes through increased returns and stabilized markets or savings in costs of production. Both are stronger in rural areas than in urban communities, although co-operative supermarkets and co-operative apartments are found in and near metropolitan centres. There has been no confluence of these streams because of strong and basic differences in viewpoint. Proponents of across-the-board co-operative effort, with emphasis on consumer services, have been more zealous in their adherence to a co-operative philosophy and ideology. They stress the high motives and ethical values of mutual endeavour. Farmer co-operatives, on the other hand underscore business objectives: higher prices for their commodities when marketed, increased savings on co-operative purchases and interest on invested capital. Although these differences are only in degree, and monetary savings gained through patronage of consumer stores and services are a prime determinant of their longevity and success, the differences are evident in the teachings and publications of the two types of organizations and there is a lack of rapport between the two groups in some areas of the United States.

**Characteristics of Co-operatives.**—In their operating technique and organizational structure, co-operatives closely resemble other types of business, and have similar motives. Distinguishing

characteristics of co-operatives are their ownership by patrons (rather than by investors who may or may not be patrons), their distribution or allocation of all net earnings annually among member-owners in proportion to their patronage, and their control by directors who are themselves members, owners and patrons. Moreover, co-operatives stress service to members to a degree that shapes their policies.

Because co-operatives are voluntary associations of patrons who may withdraw from membership in any year, they are peculiarly dependent upon members' active participation and loyalty. Some co-operatives (e.g., processing associations) require large sums of capital for plant and equipment which must be provided by members in proportion to their patronage. This capital may be obtained through revolving capital funds derived from the proceeds of marketing, through a surcharge added to the cost of supplies purchased, through a capital allowance in service fees or through stock subscriptions. Although this capital is seldom retained for a period in excess of 10 years (since it is accumulated annually and rotated accordingly), it often involves large investments by member-patrons at a given time. Thus, member relations are a vital aspect of co-operative affairs. Research studies disclose a positive correlation between members' knowledge of their co-operative and their loyalty and patronage. In those co-operatives with membership numbering tens of thousands, information and education become massive responsibilities.

In general, co-operatives in the U.S. are decreasing in numbers and increasing in size and membership. In the face of powerful competition, some co-operatives have been eliminated and others have merged. Some local associations are part of nationwide organizations such as the Farm Credit system and the Rural Electrification administration. Many regional and federated associations have members in several states.

A common ethnic background, similarity of interests and employment, and comparable income levels all contribute to harmony of interests among members. In predominantly Scandinavian communities, support and patronage of co-operatives are firmly established. This is probably the principal reason why the greatest concentration of co-operative organizations and membership in the United States is in the north central region lying west and south of the Great Lakes, where the large Scandinavian population favoured the formation and early growth of co-operatives with success that has been self-perpetuating. For quite different reasons, California is the state in which annual dollar volume of business through farmer co-operatives is greatest. California co-operatives, primarily engaged in processing, packing and marketing farm commodities, were organized in the early decades of the 20th century and gained national recognition for their rigid standardization of product grade and quality, their promotion of brand names and their consistent efforts toward orderly marketing. These organizations are constantly exposed to keen business competition and the critical appraisal of their members.

With the growth of chain stores in the retail grocery and drug business there has been a marked expansion of wholesale buying co-operatives. These are owned and patronized by supermarkets and proprietary grocery stores seeking bargaining power commensurate with their chain store competitors and savings derived from quantity purchases.

In contrast to those of many other countries, co-operatives in the U.S. have been encouraged, but not financially supported, by the federal government. In general, farmer co-operatives have received more assistance than those of other types. Marketing associations organized and operating in accordance with the provisions of the Capper-Volstead act of 1922 receive specific consideration under antitrust laws; the Co-operative Marketing act of 1926 established a division under the U.S. department of agriculture to render services to associations of agricultural producers engaged in co-operative activities. Those co-operatives which distribute all net earnings among their patrons annually and adhere to special stipulations of the internal revenue code (relative to the identity and equitable treatment of patrons, rate of returns on invested capital, accumulation of reserves and record-keeping) may qualify for a "letter of exemption" from federal income

taxes. Since the co-operative thus retains no net income, its earnings are taxed as income to the individual patrons who receive it. Other types of co-operatives pay federal income taxes. All co-operatives are subject to all other types of taxation.

The federal government has facilitated the growth of two major types of co-operatives through loans: (1) rural electric associations, which may borrow from the Rural Electrification administration; (2) land bank and production credit associations, which were initially provided with funds through the component banks of the Farm Credit administration. The latter include district federal land banks, intermediate credit banks and banks for co-operatives, which lend directly to farmer co-operatives. The federal funds that originally implemented this nationwide farm credit system were gradually replaced by borrower stock subscriptions. By the early 1960s all three types of lending institutions under the Farm Credit administration were approaching borrower ownership in the co-operative tradition. The 1,000 rural electric co-operatives that function in 45 states have played a major role in electrification of more than 90% of all farms in the U.S.

Several national organizations serve co-operatives. The American Institute of Cooperation in Washington, D.C. promotes co-operative research and serves as a source and clearinghouse for co-operative information. The Cooperative League of the U.S.A. in Chicago, Ill., a federation of co-operatives dealing with consumer goods and farm supplies and services, functions as an educational and training agency and as a spokesman for co-operative principles. The National Council of Farmer Cooperatives in Washington, D.C. represents co-operatives before congress and before executive agencies of the federal government and assists in co-ordinating co-operative views on matters of national policy. State co-operative councils perform parallel functions within their respective boundaries. In addition, there are several nationwide associations that follow specific commodity or service lines, including the National Milk Producers federation, the National Federation of Grain Cooperatives and the National Rural Electric Cooperative association. (A. W. L.)

## OTHER COUNTRIES

**Africa and Near East.**—The co-operative movement grew rapidly in Africa after World War II, aiding the technical advancement of primitive agricultural economies by making available farm machinery, credit, a marketing system and training in new methods. The co-operatives generally followed the pattern established by the mother country. In the British territories the government actively encouraged the co-operative movement and appointed registrars to assist in organizing and supervising the new co-operatives. In Nigeria, cocoa marketing co-operatives began in 1922 and were followed by other marketing, credit and consumer co-operatives. In other sections of British West Africa produce-marketing co-operatives were introduced. After World War II membership in co-operatives in British East and Central Africa was extended from Europeans to the African population. Marketing societies added processing functions and began to operate cotton gins and coffee-processing plants. In Kenya, new African co-operatives were patterned after the existing European and Asian societies.

In French West Africa the government's attempt to convert native provident societies into co-operatives resulted in some failures. The authorities then set up pilot marketing co-operatives and rural producers' mutual societies to promote co-operative development. In Belgian territories there was a slower development and some failures due to inadequate preparation. Ghana had an early history of co-operatives in the production and marketing of cocoa, but consumer co-operatives declined because of the competition of credit stores. South Africa had the most advanced development of co-operatives on the continent, chiefly in consumer and agricultural marketing co-operatives for Europeans. The Cooperative Winegrowers' Association of South Africa controlled the entire wine industry.

In north Africa many societies were founded by Europeans and were later extended to include Africans. The Algerian agricultural co-operatives included wine cellars and agricultural equipment

societies. Morocco's co-operatives were primarily in agricultural marketing, production and handicraft societies. In Tunisia, craftsmen were encouraged to pool their effort in co-operative workshops and marketing societies.

In the Arab League countries consumer co-operatives were weak because people preferred to shop in the bazaars. Agricultural co-operatives were developed through government action to improve land utilization and reduce the traditional indebtedness of farmers. Credit and housing co-operatives appeared in Turkey, Jordan, Egypt and Iraq. Government co-operative departments were established in most of these countries to encourage the growth of the movement.

In Israel co-operatives flourished under a distinctive association with the labour movement. "Hevrat Ovdim," the General Cooperative of Jewish Labor, was a subsidiary of "Histadrut," the General Federation of Labor. Co-operative agricultural communities accounting for 50% of the total rural population, were of the following types: the "Kibbutz" and "Kvutza," where all property is collectively owned and work is organized collectively; the "Moshav" and "Moshav Ovdim," co-operative settlements where all farms are of equal size; and "Moshav Shitufi," a co-operative settlement where all property, except individual farms, is owned collectively.

**Canada.**—The earliest co-operative developments in Canada were in agricultural marketing. The United Grain Growers' Ltd. was founded in 1906, the United Fruit Companies of Nova Scotia in 1912, and the Associated Growers of British Columbia in 1923. The Canadian Cooperative Wheat Producers, Ltd. was organized in 1924 as the central selling agency for the wheat pools. Other important marketing societies were for honey products, forage, livestock, poultry and maple sugar. Altogether more than 30% of all Canadian farm products were marketed through co-operatives in the late 1950s. Consumer co-operatives in retail trade were organized chiefly in rural areas and mining towns. Canada had a strong credit movement, serving chiefly the rural areas and filling gaps in the banking system. The 5,000 co-operative credit unions were grouped into 26 central banks, which were affiliated with the National Federation of Cooperative Credit, which was in turn affiliated with the corresponding organization in the United States. The French-speaking area was represented by Le Conseil canadien de la coopération, which comprised 6 provincial unions, including the Federation of Quebec with 1½ million members.

**Australia and New Zealand.**—The first co-operatives in Australia were organized in 1868. By the time the Cooperative Federation of Australia was founded in 1943 the membership of individual societies had reached 500,000, mainly in New South Wales. Among the most important organizations were the Co-operative Dairy association of New South Wales, the Poultry Farmers' Cooperative society of Queensland and the Trustees of the Wheat Pool of Western Australia. In New Zealand more than 300 co-operative cheese and butter factories dominated the co-operative movement.

**Latin America.**—The co-operative movement in Latin America was launched by European immigrants as early as 1900, and was later fostered by state action in connection with agrarian reform. The chief co-operatives are agricultural, credit, housing and consumer types. By the early 1960s there were about 15,000 co-operatives with about 5,000,000 members. The Union of Argentine Cooperative societies was founded in 1922, and in Brazil the Central Cooperative of Rural People's Banks of Rio Grande do Sul was established in 1925. Consumer co-operatives were strong in Argentina, Brazil and Chile. Many were established by business firms or government departments for their own employees, and usually received tax exemptions. Agricultural co-operatives were established in every Latin-American country. By the middle of the 20th century Argentina had six federations of general agricultural marketing co-operatives, including the "Sanctor" Butter factories founded in 1938. Brazil had 1,300 agricultural production co-operatives for such products as sugar cane, cocoa, bananas, coffee, maté, timber, wine and rice. Chile had agricultural co-operatives for dairy products, poultry, fruit, cattle and forestry. Among the agricultural co-operatives in Uruguay

were those for livestock, cereals and rice, dairies, fruit and flowers.

Credit and insurance co-operatives were also firmly established. The Association of Argentine Mutual Insurance cooperatives was founded in 1940, and had 88,000 members by 1960. The Federation of Argentine Credit cooperatives, founded in 1950, included 50 societies and 35,000 members. Brazil had 444 credit unions. The Chilean Federation of Savings cooperatives, founded in 1951, included 98 credit co-operatives. The Cooperative Union of the Dominican Republic functioned mainly in credit, and represented 100 credit and insurance societies.

In Mexico the *ejidos* (land-owning villages) provided a system of co-operative farming and community improvement. There were also production co-operatives in forestry, fishing, transportation, mining and services. A major consumer co-operative was organized and managed by the trade unions. The Mexican National Bank for the Development of Cooperation was founded in 1944 to provide credit to co-operatives and small businesses.

**Asia.**—In Communist China co-operatives are defined as a form of collective ownership by the workers. The first-five year plan called for the collectivization of agriculture through the intermediate stages associated with the Communist bloc in eastern Europe, and for the gradual organization of individual handicraft workers and private merchants into co-operatives. Wholesale trade in industrial products was to be handled by state trading companies; handicraft products and other retail trade were to be handled by the co-operatives. By the end of 1956, 92% of all handicraftsmen had been drawn into co-operatives; most of the operators of wagons, wheelbarrows and junks became members of transport co-operatives; and the majority of fishermen, salt miners, peddlers and human carriers were organized into other co-operatives. By the end of 1958 the socialization of agriculture was declared to be complete, without having gone through the scheduled intermediate stages. Communist party workers were in charge of co-operatives and collectives.

The co-operative movement in Indonesia had advanced steadily before World War II, but lost ground under Japanese occupation. The first constitution of the republic in 1945 specifically provided for co-operative organization. With the authoritarian government established in 1960, it was anticipated that the co-operatives would become subservient to a state-controlled economic plan.

In India the plan to establish a co-operative in every village embodied the national policy to assign a major role to co-operatives in achieving economic development. The second five-year plan called for an expansion of the multipurpose village societies from 5,000,000 to 15,000,000 members. A government training program was established with a staff of technical advisers to work through the local co-operatives and the village schoolmasters. The Reserve Bank of India was instrumental in distributing agricultural credit, organizing training programs, and otherwise assisting co-operative development. Short-term credit was available through 180,000 credit societies. Production and marketing co-operatives were widely organized for handloom weavers, sugar cane growers, spinners and cottage industries.

In Pakistan at the end of 1957 there were 21,000 co-operatives with a membership of 1,000,000, chiefly in agricultural credit societies. The co-operative movement was also actively promoted in Ceylon, Burma, Malaya and the Philippines. Consumer co-operatives were particularly active in Ceylon, in addition to agricultural credit societies.

In Japan, co-operatives were first established in the 1870s and by the end of the century had 65,000 members, chiefly in the farm villages. With government encouragement the number increased to 380,000 by 1909. After World War I the farm co-operatives were used to carry out the government's economic recovery plan. Fishermen's and workers' production co-operatives also developed rapidly in this period. By World War II, all of these co-operatives had become state agencies and had lost their independence. After the war, co-operatives were reorganized under new laws. Agriculture and fishing were almost completely organized into co-operatives by the early 1960s. Industrial, commercial and consumer co-operatives were growing less rapidly.

**U.S.S.R.**—Consumer co-operation began in Russia with the

abolition of serfdom in 1865, and by the end of the century total membership was about 250,000. The revolution of 1905 resulted in the promotion of co-operatives as a means of social improvement, and by 1914 membership had grown to over 1,000,000. During World War II the government controlled distribution through co-operatives, and in the postwar era their scope was determined by political exigencies. In 1958 the Central Union of Consumer cooperatives had a membership of 34,000,000 and accounted for 29% of the total retail trade of the U.S.S.R. When producer co-operatives were included in the state planning system most private handicraft workers were induced to join by means of discriminatory taxes or benefits. The "artel" was the main type of co-operative; under this arrangement the shop and equipment were communally owned, each member received a wage, and the annual surplus was distributed in proportion to individual output. The formation of farm co-operatives was advocated by Lenin as a practical method of introducing agricultural collectivization. The complete collectivization drive of the 1930s was later modified because of peasant resistance, and each family was permitted to have a farmstead for its personal use, consisting of about half an acre, a few livestock and some tools.

**Eastern Europe.**—Co-operatives had attained a considerable growth in this area before World War II; at least 15% of the population belonged to some type of co-operative. As the Soviet Union gained control of each country the basic pattern of socialization was to establish direct state control of large industries and to promote gradual collectivization of the rest of the economy. Collectives were represented as an advanced form of the traditional co-operative. Agriculture was to be reorganized in four stages: (1) machinery was to be used collectively; (2) fields were to be worked in common but still owned individually; (3) all property was to be pooled except the small private farmstead; (4) all land was to be pooled and all income was to be distributed in proportion to the work performed. After fulfilling the quota set for each collective according to its fertility, making deposits in established funds, and paying other expenses, the surplus was distributed in proportion to the number of workday units contributed. Any surplus from the farmstead could be sold in a free market. State farms were directly owned and managed by the state, and the employees were paid regular wages.

The typical organization of trade was through a pattern of state stores in urban centres and co-operatives in rural areas. In either case, the operation was in the hands of the political party, which determined quotas and prices in consonance with the national economic plan. Distribution of the surplus was made according to labour contribution rather than to sales and purchases. Producer co-operatives in the cottage or handicraft industries were encouraged because they could provide additional consumer goods at low cost by using local raw materials and local markets, and because skilled workers were thus gradually brought under socialism.

In Albania, the government was reported in the early 1960s to be relying heavily on the co-operatives in its attempt to develop commerce and agriculture. In Bulgaria many of the economic functions carried out by co-operatives were assigned to state organizations, especially the distribution of food products, the sale of agricultural supplies, agricultural marketing, credit and insurance.

In Czechoslovakia, both consumer and agricultural co-operatives were strong before the German invasion of 1938. There was a rapid revival after World War II, when many private businesses were transformed into co-operatives. Retail trade was socialized between 1946 and 1952. The consumer co-operatives during the late 1950s operated 42,000 stores, 15,000 restaurants and 282 training schools.

In Hungary, the government established a close relationship with co-operatives under the Horthy regime. After the war, co-operatives were extended but were dominated by the state and linked with state-owned businesses.

The agricultural circle was revived in Poland as an alternative to the collective farm; it provided for co-operative use of new machinery, irrigation systems and local processing plants, but

retained private ownership of property. Producer co-operatives provided 11% of total production; in retail trade 64% of the stores were co-operatives and 30% were state stores.

When industries were nationalized in Rumania in 1948, individual producers were organized into state-controlled co-operatives affiliated with a federation under close government supervision. In the late 1950s they accounted for the production of 30% of clothing, 34% of furniture and a high proportion of small metal goods.

In Yugoslavia the government liberalized its policy of agricultural collectivization and encouraged the spread of privately-owned co-operatives. Individual holdings were limited to 25 ac. each and personal control was maintained.

**Western Europe.**—The co-operative movement in western Europe underwent major changes after World War II. Consumer co-operatives introduced self-service stores and merged some of their units to reduce costs. Agricultural co-operatives developed marketing and processing facilities to provide more complete vertical integration.

Co-operatives had been formed in Germany in the middle of the 19th century. The system of rural credit originated by F. W. Raiffeisen was later copied throughout the world. At the same time, F. H. Schulze-Delitzsch pioneered in establishing banks for small business loans. These were revived in the Federal Republic of Germany after World War II, and within a decade claimed 5,000,000 members. Consumer co-operatives also recovered quickly after the war, claiming over 2,000,000 members.

In France the first consumers' store was founded in 1835, but the main early development was in producers' societies. By 1960 consumer co-operatives had 3,000,000 members and agricultural co-operatives had more than 1,000,000 members. It was estimated that 82% of all grain and 60% of all oil-producing crops were marketed through co-operatives. The 600 workers' production co-operative societies were found mostly in building, quarrying, books, paper, metallurgy and electricity.

The Scandinavian countries are strongly organized for both consumers' and agricultural co-operation. In rural areas purchasing and marketing co-operatives are common; in urban areas the consumer co-operatives have food stores, department stores, bakeries and apartments. A Cooperative Union and Wholesale society in each country provides goods and miscellaneous services to the affiliated consumer co-operatives, and may also operate productive enterprises. By 1960 the percentage of the population belonging to co-operatives was 24% in Finland, 21% in Iceland, 14% in Sweden, 11% in Denmark and 8% in Norway.

In Sweden there were over 1,000,000 members of farm co-operatives in 1960. Consumer co-operatives handled 12% of all retail trade; housing co-operatives represented 100,000 members and worked with municipal authorities to build low-cost housing. In Norway the sale of fish is handled exclusively by the co-operatives. Dairying co-operatives are also particularly strong. Denmark has a long record of agricultural and consumer co-operatives, including a co-operative theatre with 115 affiliated societies.

In Italy, the co-operative movement lost its freedom with the rise of Mussolini in the early 1920s. In the expansion that followed World War II the co-operatives split into two major federations, each representing 10,000 co-operatives and more than 2,000,000 members. Agricultural and consumers' co-operatives were the most numerous.

Among the 5,000 agricultural co-operatives in Spain, the most important groups were wine cellars, oil factories, mills, dairies and rural credit banks.

Austrian co-operatives lost their autonomy during the German occupation but were re-established in 1947. By 1957, agricultural marketing co-operatives had 1,000,000 members. In urban areas, credit co-operatives claimed 750,000 members and consumer co-operatives had 355,000 members.

Before World War II, consumer co-operatives in Belgium handled 10% of all retail trade and served 25% of the population. The postwar revival retained the compartmentalized organization which had developed. The Belgian Farmers' league represented

marketing and credit co-operatives, with a membership of 250,000. The National Federation of Christian cooperatives operated 1,200 stores for its 145,000 members. "L'Économie populaire" operated 320 stores for 60,000 members. The Federal Cooperative society had 217,000 members, and the General Cooperative society served 340,000.

In the Netherlands agricultural marketing and supply co-operatives were divided along religious lines. Consumer co-operatives serve about 15% of the population, chiefly in urban areas.

In Switzerland, the most important wholesale co-operative started a wartime movement to intensify land cultivation. By the end of 1946, 42% of Swiss families were members of consumer co-operatives. These were extended after the war to the production of flour, furniture, shoes and miscellaneous consumer goods. Agricultural co-operatives came to be particularly active in the dairy industry.

**COOPERSTOWN**, a village of eastern New York, U.S., seat of Otsego county, about 60 mi. W. of Albany at the foot of Otsego lake where the Susquehanna river emerges.

In 1779 an army of American patriots under Gen. James Clinton assembled at the present site of Cooperstown where a dam had been built to raise the level of the lake. Breaking the dam, Clinton floated his supplies down the swollen Susquehanna as he moved his force to join Gen. John Sullivan for their successful campaign against the Iroquois and their Loyalist allies. Judge William Cooper of Burlington, N.J., the father of the novelist James Fenimore Cooper, founded the village in the spring of 1786. His policy

of selling land outright and accepting mortgages in payment attracted many settlers and probably influenced other great landholders to follow his example. Incorporated in 1807, Cooperstown became a thriving commercial and transportation centre.

James Fenimore Cooper spent his boyhood in his father's mansion which overlooked Otsego lake. The scenes and stories of his childhood are reflected in his *Leatherstocking Tales*. Otsego lake is the Glimmerglass of his novels.

Cooperstown was the home of Erastus F. Beadle, who originated the dime novel, and of Samuel Nelson, a justice of the U.S. supreme court. Abner Doubleday (later a general in the U.S. army) was said to have devised the modern game of baseball in Cooperstown in 1839 and the National Baseball Hall of Fame and Museum are located there. (See *BASEBALL: History of Baseball*.) Cooperstown is the headquarters of the New York State Historical association which operates Fenimore house and the Farmer's museum in the village. The Historical association has one of the nation's best collections of American folk art. Mary Imogene Bassett hospital in Cooperstown is a notable centre of medical research. Every summer thousands visit Cooperstown to enjoy its museums and beautiful scenery. (J. A. Fr.)

**COOPER UNION**, an educational institution at Cooper square, New York city, founded by Peter Cooper in 1859. In endowing the school, Cooper stipulated that it be "forever devoted to the advancement of science and art." The Hewitt and Carnegie families and others later increased the Union's financial resources.

Green Camp, a 1,000-ac. tract from the ancestral estate at Ringwood, N.J., given by Norvin H. Green, Cooper's great-grandson, was opened in 1941 as a year-round educational and recreational facility. In 1955 the institution acquired the historic Bible house property adjacent to its original site and in 1960 a new school of engineering building was constructed there.

All instruction is tuition-free and open to all who meet the entrance requirements, regardless of race, creed or colour. Day and evening students are selected from among many applicants on the basis of rigorous intelligence and aptitude tests. The school of engineering confers the degrees of bachelor of chemical, civil, electrical and mechanical engineering; the art school awards degrees and certificates in the fine and graphic arts and in architecture. In 1939 a department of humanities and social studies was established to function as an integral part of undergraduate professional education.

The adult education division conducts evening courses. Free lectures and programs of music, dance and drama are given in the Great hall, where on Feb. 27, 1860, Abraham Lincoln gave his famous Cooper Union address in which he championed the right of the federal government to prohibit slavery in the territories. Many national agencies for social uplift and welfare were founded there, and a number of United States presidents have spoken in the hall.

The Museum for the Arts of Decoration, opened in 1897, provides important resources for designers in the decorative arts. Its collections include original drawings and designs, textiles, woodwork, furniture, metalwork, glass, ceramics and wallpaper. Free exhibitions are offered frequently.

The library, first free public reading room in New York, has nearly 100,000 volumes, as well as extensive holdings of current journals, magazines and trade catalogues. The reference library is supplemented by an encyclopaedic picture reference collection of classified photographs and clippings. (E. S. Bl.; F. A. Cu.)

**CO-OPTATION**, the election to vacancies on a legislative, administrative or other body by the votes of the existing members of the body, as opposed to election by an outside constituency. Such bodies may be purely co-optative, like the governing boards of most private U.S. universities, or elective with power to add to the numbers by co-optation. An example of the latter is the municipal corporations in England, which have statutory authority to co-opt persons who are not elected members of the councils to serve on certain of their committees. (C. H. P.)

**CO-ORDINATES**, real numerical quantities, specified with respect to some frame of reference, that determine the position of a point on a plane or in space. To each set of co-ordinates in a given co-ordinate system there corresponds one and only one point. For a detailed discussion of the important types of co-ordinate systems used by mathematicians, see ANALYTIC GEOMETRY.

See also references under "Co-ordinates" in the Index volume.

**CO-ORDINATION COMPOUNDS** are chemical compounds the atoms or groups of which are united by bonds or valences supplementary to those assigned by the classical theory of valence to the substances of which they are composed. The term was coined by Alfred Werner, who announced the *Co-ordination Theory* in 1893 in order to explain the existence of addition compounds and double salts, such as amines, hydrates and the double cyanides. The classical theory of valence (*q.v.*) did not explain, for example, the fact that copper chloride,  $\text{CuCl}_2$ , combines with ammonia,  $\text{NH}_3$ . Werner postulated that the ions of metals such as copper have not only the usual or "primary" valence bonds, which hold the atoms of chlorine in  $\text{CuCl}_2$ , but also "secondary" or "co-ordinate" valence bonds, by which they may attach themselves to other molecules or negative ions. Werner called the resulting substances "compounds of the higher order" or "co-ordination compounds." Werner's theory, restated in electronic terms by both Nevil V. Sidgwick and Thomas M. Lowry in the 1920s, has become one of the foundation stones of the knowledge of molecular structure. Positive ions, especially those which are small and highly charged, share electrons from adjacent negative ions or neutral molecules which have unshared electrons. The metal ion is referred to as the "acceptor" and the other group the "donor" of electron pairs. Thus, when platinum chloride is treated with an excess of ammonia, the hexammine platinum ion is formed:

That chemical union has taken place is indicated by changes in colour, solubility and other properties, and by the fact that the material does not respond to the usual chemical tests for either the platinum ion or ammonia. Other molecules having unshared pairs of electrons may be substituted for the ammonia; *e.g.*, water,  $\text{H} : \ddot{\text{O}} : \text{H}$ , organic amines,  $\text{R} : \ddot{\text{N}} : \text{H}$ , organic sulfides,  $\text{R} : \ddot{\text{S}} : \text{R}$ , and many others. Similarly, negative ions such as chloride,  $:\ddot{\text{Cl}}:$ , and cyanide,  $:\text{C}::\text{N}:$ , often enter the co-ordination sphere; chloroplatinic acid is a typical co-ordination compound:

or simply  $\text{H}_2\text{PtCl}_6$ .

Two or more different donor groups may be present in the complex simultaneously. Between the hexammine and the hexachloroplatinic ions there are the chloropentammine ion,  $[\text{Pt}(\text{NH}_3)_5\text{Cl}]^{3+}$ , the dichlorotetrammine ion,  $[\text{Pt}(\text{NH}_3)_4\text{Cl}_2]^{2+}$ , the trichlorotriammine ion,  $[\text{Pt}(\text{NH}_3)_3\text{Cl}_3]^+$ , tetrachlorodiammine platinum,  $[\text{Pt}(\text{NH}_3)_2\text{Cl}_4]$ , and the pentachloromonoammine ion,  $[\text{Pt}(\text{NH}_3)\text{Cl}_5]^-$ .

Chloro-aquatetrammine cobaltic ion,  $[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})\text{Cl}]^{2+}$ , is a more complex type, in which three different donor groups are co-ordinated to the central ion.

The number of donor groups with which the central ion can combine is more or less fixed for each metallic ion, and is called the co-ordination number. According to Sidgwick, the maximum co-ordination number of any ion depends upon the atomic number of the element; for hydrogen, it is 2; for elements 3 to 9, it is 4; for elements 11 to 35, it is 6; for the heavier elements, it is 8. Usually these maxima are not reached, but in a few examples, such as  $\text{CaCl}_2 \cdot 8\text{NH}_3$ , they appear to be exceeded.

A donor atom having more than one pair of unshared electrons may combine with two metallic ions, thus binding them into a dinu-

clear complex.

There are often two or three "bridge groups" as:

Many polynuclear complexes are known. Among these are the highly polymeric prussian blue,  $\text{K}[\text{Fe}[\text{Fe}(\text{CN})_6]]$  and the polymeric, insoluble hydroxides of metals. Thus, ferric hydroxide, the formula of which is usually written  $\text{Fe}(\text{OH})_3$ , is actually a three dimensional polymer  $[\text{Fe}_n(\text{OH})_{3n}(\text{H}_2\text{O})_x]$ , the ferric ions being held together by mutual sharing of electrons from the OH "bridges." This substance may lose hydrogen ions, either from the hydroxo bridges, or from the water molecules. In the first case, "oxo" bridges result; in the second, new hydroxy groups are generated and these may form additional bridges with other ferric ions. Platinous chloride is a linear, doubly bridged polymer:

If two donor atoms are present in the same molecule, but separated by at least one other atom, they may both co-ordinate with the same metallic ion, forming a "chelate" ring. The stability of co-ordination is greatly enhanced by this chelation effect if the ring is of suitable size; five-membered rings are the most stable, if only single bonds are present in the ring structure. In rings containing double bonds, six members give the greatest stability, but those containing four or six members are easily prepared. This effect may be illustrated by the organic amines. Monoamines such as methylamine,  $\text{CH}_3\ddot{\text{N}}\text{H}_2$ , co-ordinate poorly, but ethylenediamine,  $\ddot{\text{N}}\text{H}_2\text{CH}_2\text{CH}_2\ddot{\text{N}}\text{H}_2$ , does so readily, forming compounds of great stability. The tris-ethylenediamine cobaltic ion, for example, is not decomposed by hot concentrated hydrochloric acid.

Simple secondary organic amines will co-ordinate scarcely at all, but diethylenetriamine,  $\ddot{\text{N}}\text{H}_2\text{CH}_2\text{CH}_2\ddot{\text{N}}\text{HCH}_2\text{CH}_2\ddot{\text{N}}\text{H}_2$ , attaches itself to cobaltic, platinum and other heavy metal ions through all three of its nitrogen atoms because of the formation of very stable double chelate rings:

Donor groups which attach themselves to a single metal ion through two atoms (*e.g.*, ethylenediamine) are referred to as bidentate, those which attach themselves through three atoms, as tridentate, and so on. The number of atoms in a chelate ring is most important in determining its stability. Thus, the cupric complexes of  $\alpha$ -amino acids (five-membered rings) are extremely stable, those of  $\beta$ -amino acids (six-membered rings) are much less stable, and those of  $\gamma$ ,  $\delta$ , and  $\epsilon$  amino acids show no tendency to ring formation at all. They are simple salts.

Among the important bidentate groups are ethylenediamine, 1, 3 diketones, and the anions of  $\alpha$ -amino acids. Since ethylenediamine is a neutral molecule, compounds formed with salts have saltlike character:

When a  $\beta$ -diketone forms a co-ordinated molecule, however, it loses a hydrogen ion and becomes a negative ion. If the charge on the metal ion balances the charges on the negative diketone ions and if the co-ordination number of the metal ion is twice its charge, a neutral molecule (not a salt) is formed. Many such substances are soluble in nonpolar solvents and are volatile. Among the "inner complexes" formed by  $\beta$ -diketones are the following:

Many of the amino acid compounds are inner complexes, but they are not volatile or soluble in nonpolar solvents. The  $\alpha$ -amino acid inner complexes have the type formula

where  $x$  is the charge on the metal ion.

Tridentate donor groups form more stable complexes than do analogous bidentate groups; tetradentate groups form still more stable complexes, and so on. In many types of chemical work, polydentate chelating agents are used to combine with metal ions that have undesirable properties, converting them to stable complexes which are not deleterious. Thus, the polyphosphate ion is used in water treatment to "sequester" calcium ions:

The hexidentate anion of ethylenediaminetetraacetic acid

is one of the most powerful co-ordinating agents known, and is used to tie up undesired metal ions in soaps, cosmetics, electroplating baths, food products and a host of other materials. It can also be used to remove rust and scale from metal surfaces, and its iron compound has found application in supplying iron to growing plants.

Many metal ions catalyze unwanted oxidations, so their conversion to noncatalytic forms is most important. Chelating agents are used to effect this in petroleum products, rubber, foods and other organic materials.

**Isomerism.**—The co-ordination compounds exhibit many types of isomerism (*q.v.*). The most important of these are illustrated as follows:

1. **Polymerism.**—Hexammine cobaltic hexanitro cobaltate  $[Co(NH_3)_6][Co(NO_2)_6]$ , which consists of two co-ordinate ions, is a polymer of the nonionic trinitrotri-amine cobalt,  $[Co(NH_3)_3(NO_2)_3]$ .

2. **Structural Isomerism.**—The nitrite ion has unshared electrons on both the nitrogen and the oxygen atoms, and can, therefore, attach itself to the cobaltic ion in two different ways. In the bright red nitrito amines, such as  $[Co(NH_3)_5ONO]^{2+}$ , the linkage is through oxygen. These compounds rearrange to the more stable brown nitro amines,  $[Co(NH_3)_5NO_2]^{2+}$ .

3. **Co-ordination isomerism**, in which groups from the positive and negative ions are interchanged, is illustrated by  $[Co(NH_3)_6][Co(NO_2)_6]$  and  $[Co(NH_3)_4(NO_2)_2][Co(NH_3)_2(NO_2)_4]$  and

by  $[Co(NH_3)_6][Cr(CN)_6]$  and  $[Cr(NH_3)_6][Co(CN)_6]$ .

4. **Ionization isomerism**, which is closely related to co-ordination isomerism, is shown by  $[Co(NH_3)_5SO_4]Br$  and  $[Co(NH_3)_5Br]SO_4$ . The first gives the usual analytical tests for bromide ion, but not for sulfate, while in the second the reverse is true.

5. Another type which is related to co-ordination isomerism is illustrated by  $[Co(NH_3)_5NO_3]^{2+}$  and  $[Co(NH_3)_4NH_2OH_2NO_2]^{2+}$ .

6. **Hydrate isomerism** is exhibited by the hexahydrates of chromic chloride,  $[Cr(H_2O)_6]Cl_3$  (gray-violet),  $[Cr(H_2O)_5Cl]Cl_2 \cdot H_2O$  (green) and  $[Cr(H_2O)_4Cl_2]Cl \cdot 2H_2O$  (green). The water molecules which are not part of the complex ion are probably held in the crystal lattice by mechanical or semichemical forces. Silver nitrate precipitates all the chlorine from solutions of the gray-violet isomer immediately, two-thirds of it from the first-mentioned green isomer and one-third from the other green isomer.

7. **Isomerism of Donor Groups.**—Either isopropylamine or normal propylamine can enter into the formation of  $[Co(ethylenediamine)_2(propylamine)Cl]^{2+}$ .

8. **Stereoisomerism.**—Co-ordinate bonds are directional, so that the co-ordinated groups occupy fixed positions about the central metal ion. The four covalences of platinum ion lie in a plane, so that compounds such as  $[Pt(NH_3)_2Cl_2]$  exist in the two forms

These differ in solubility and in chemical behaviour. Many such examples are known, not only for platinum, but also for palladium, nickel and many other metals.

On the other hand, many complex ions and molecules containing four donor groups have been shown to have a tetrahedral configuration. Nickel carbonyl,  $[Ni(CO)_4]$ , and the complex cyanides of zinc, cadmium and mercury,  $[M(CN)_4]^{2-}$ , belong in this class.

When there are six co-ordinated groups, they occupy the corners of an octahedron, and if two of the groups are different from the other four, cis-trans isomerism is possible. The cis form of  $[Co(NH_3)_4Cl_2]^+$  is violet, while the trans form is green:

If three of the co-ordinated groups are alike, but different from the other three, isomerism is again possible:

9. **Optical isomerism** is shown when the co-ordinated groups (either four, six or more) are asymmetrically disposed about the central metallic ion. This is easily achieved if the complex ion contains chelate rings. Thus, tris-ethylenediamine cobaltic ion exists in mirror image forms which cannot be superimposed:

The same is true of the *cis* form of the dichloro-bis-ethylenediamine cobaltic ion, but not of the *trans* form:

Optical activity might be achieved by proper arrangement of nonchelating groups, but apparently only one attempt has been made to study such a case. I. I. Chernaev prepared the ion  $[\text{Pt}(\text{NH}_3)(\text{pyridine})(\text{NH}_2\text{OH})(\text{NO}_2)]^+$ , which should be resolvable into optically active forms if the valences of the platinum are tetrahedral, but which should exist in three isomers of the *cis-trans* type if the valences lie in a plane. He discovered the latter to be the case. An octahedral ion containing six different groups should exist in 30 different forms—15 pairs of mirror-image isomers.

The stereochemistry of co-ordination numbers 2, 3, 5, 7 and 8 is much less well developed than that of co-ordination numbers 4 and 6, and few cases of isomerism have been discovered for these co-ordination numbers. The stereochemistry of these less familiar co-ordination numbers has been studied by physical means, such as X-ray crystal analysis, and by measurements of the spectra, dipole moments and magnetic properties.

#### Some Important Types of Co-ordination Compounds.—

Aside from the ammines and the hydrates, there are many important types of co-ordination compounds. The complex cyanides of the heavy metals find wide application in electroplating baths. Ferric ferrocyanide, or prussian blue, and many other highly coloured co-ordination compounds, such as the metal derivatives of the azo dyes, also find application as pigments. Hemoglobin and chlorophyll are naturally occurring co-ordination pigments; they find a counterpart in the synthetic phthalocyanine pigments, which are deep blue or green in colour.

The metal carbonyls (*q.v.*) constitute an interesting group of co-ordination compounds in which the classical rules of valence would indicate a valence of zero for the metal. Many of these substances are volatile. Nickel carbonyl,  $[\text{Ni}(\text{CO})_4]$ , for example, is a highly refractive volatile liquid which is readily formed by the action of carbon monoxide on finely divided metallic nickel. This reaction has been utilized in the metallurgical separation of nickel from cobalt, copper and other metals. Nickel carbonyl is also used in the preparation of nickel powder for catalytic purposes. Iron carbonyl,  $[\text{Fe}(\text{CO})_5]$ , is used in the preparation of pure iron powder. At one time it also found limited use as an antiknock in gasoline, but it was superseded for this purpose by lead tetraethyl. In some of the carbonyls, part or all of the carbon monoxide may be replaced by nitric oxide, giving carbonyl nitrosyls, such as  $[\text{Fe}(\text{CO})_2(\text{NO})_2]$ .

Unsaturated hydrocarbons co-ordinate with many metals through the double bond. This type of co-ordinate bond is of great importance in many reactions involving unsaturated hydrocarbons; such reactions are common in the paint, rubber and petroleum industries.

The ability of  $\alpha$ -amino acids to form stable co-ordinate links, to which reference has already been made, is shared by many derivatives of these acids, and the chrome tanning of leather is sometimes explained on the assumption that the chromic ion forms stable inner salts with the polypeptides of the hide. The formation of insoluble inner salts is often used to test for the presence of specific metallic ions, and to determine their amount.

**COORG**, a district of the state of Mysore (*q.v.*), India, after 1956, was formerly an independent kingdom and later a small

province of British India. It lies at the southern end of the Western Ghats. Pop. (1961) 322,829. Area 1,587 sq.mi. The district is divided into three talukas, Mercara, Virajpet (Virarajendrapet) and Somwarpet. The name Coorg is probably a corruption of Kodagu, meaning "steepness" wherefore under the British regime, it was sometimes called the Wales of India. It is a rugged mountainous district with a high rainfall and the climate is pleasantly tempered by the altitude. Some of the hills (which rise from the general Mysore plateau surface) reach more than 5,000 ft. (Pushpagiri, 5,620 ft.; Kottebetta, 5,375 ft.). Their summits are covered with grass while their slopes are thickly forested. The valley bottoms, cleared of forest, are devoted to the cultivation of rice, which is the staple food crop of the people. Coffee plantations, dating from 1854, occupy considerable hillside clearings. One of the principal sources of the Cauvery river is in Coorg. In legend the rivers of Coorg have something of the life-giving properties of the Ganges (*q.v.*).

From the 9th century onward the mountain kingdom of Coorg remained independent, though under various rulers such as the Gangas, Cholas and Hoysalas. In 1780 it was conquered by Haider Ali (*q.v.*). The people rose in rebellion and freed themselves of Muslim rule, but later Tipu Sultan (*q.v.*) plundered the territory. The raja entered into a treaty with the English and after the final defeat of Tipu (1799) the territory was restored to him. It enjoyed complete freedom during the reign of Virarajendra (Vira Raja). Later troubles resulted in the pensioning of the raja and Coorg became a British Indian province.

The chief centre (the old capital of the kingdom of Coorg) is Mercara (Madhu-keri), situated at an elevation of 3,800 ft. Pop. (1961) 14,453. The site was selected by Mudda Raja in 1681 because of its central yet inaccessible situation and the capital was transferred there from Haleri. Linge Raja built the fort in 1812; to the south of it is the picturesque little garden known as Raja's Seat, commanding a magnificent panoramic view. Other tourist attractions include the Onkeshwara temple, a curious blend of Hindu and Islamic architectural styles. The degree-granting college, founded in 1957, is affiliated to the university of Mysore. Mercara is on the main highway from Mysore to Mangalore, 75 mi. from Mysore city. (L. D. S.)

**COOSA**, a river of northwestern Georgia and eastern Alabama, 286 miles long, is formed by the confluence of the Etowah and Oostanaula rivers at Rome, Ga. It flows southward through the Appalachian ridge and valley province onto the gulf coastal plain at Wetumpka, Ala. Its course is southwesterly into Cherokee county, where it receives the Chattooga river, then southwest past Gadsden, Childersburg, and Talladega Springs. Four miles southwest of Wetumpka and ten miles north of Montgomery, it joins the Tallapoosa river to form the Alabama river. Locks and power dams make navigation possible for barges to Rome. These power dams are the Lay, Mitchell and Jordan, located between Wetumpka and Talladega Springs. (M. C. P.)

**COOT**, an inland water-dwelling bird of the genus *Fulica*, belonging to the rail family, Rallidae. About ten species are found throughout the world in larger inland waters and streams, where they swim and bob frequently for food, which consists of water plants; seeds, mollusks and worms; occasionally, when the bird forages on land, small reptiles and mice are pursued.

Members of the genus have greenish or bluish-gray feet, the toes of which are fringed by a lobed membrane that facilitates swimming and walking over plant-choked marshes and ooze.

The European coot (*F. atra*) breeds abundantly in many northern parts of the old world, in winter resorting to river mouths or shallow bays of the sea. About 18 in. in length and sometimes more than 2 lb. in weight, the seemingly short-winged coot appears to rise with difficulty from the water, pattering along the surface with its feet. However, it is capable of long-sustained and rapid flight.

Although it is not considered a game bird, it is hunted in winter when it is most gregarious. When wounded it is said to clutch the weeds at the bottom. The coot nests in masses of water plants where it lays as many as ten speckled eggs. The young are beautifully clothed in jet-black down, with heads of a bright orange-

JOHN MARKHAM

EUROPEAN COOT (*FULICA ATRA*)

scarlet, varied with purplish-blue. This brilliant colouring is soon lost, and they assume the sooty black plumage which is worn for the rest of their lives; a characteristic of the adult is a bare white patch or callosity on the forehead.

An African species (*F. cristata*) is distinguished by two red knobs on its forehead. The North American mud hen (*F. americana*) closely resembles the European bird. In South America about six species are found, one (*F. gigantea*) being of considerable size; a species (*F. caribaea*) occurs also in the West Indies. The remains of a large extinct form (*F. newtoni*) were discovered in Mauritius.

See also RAIL.

**COOTE, SIR EYRE** (1726-1783), British soldier, who served as commander in chief in India under Warren Hastings, was born near Limerick, in Ireland, the sixth son of a clergyman. He saw active service in the Jacobite rising of 1745 and a few years later obtained a captaincy in the 39th regiment, which was the first British regiment sent to India. In 1756 a part of the regiment, then quartered at Madras, was sent forward to join Clive in his operations against Calcutta. After the battle of Plassey Coote led a detachment in pursuit of a French force for 400 mi. under extraordinary difficulties. His conduct won him the rank of lieutenant colonel and command of the 84th regiment. In Oct. 1759 Coote's regiment arrived to take part in the decisive struggle between French and English in the Carnatic; in 1760 he led them in the decisive victory of Wandiwash (Jan. 22). Coote supported Col. William Monson in the siege and capture of Pondicherry and soon afterward (1761) was given command of the East India company's forces in Bengal. In 1762 he returned to England, receiving from the company rewards for his services. In 1769 he proceeded to India as commander in chief but quarreled with the governor and again returned to England. He was knighted in 1771. In 1779 he returned to India as lieutenant general and commander in chief. Following generally the policy of Warren Hastings (*q.v.*), he nevertheless refused to take sides in the quarrels between the governor general and his council and made a firm stand in all matters affecting the army. Haidar Ali's progress in southern India called him again into the field, but his difficulties were great and it was not until June 1, 1781, that the decisive defeat of Porto Novo struck the first heavy blow at Haidar's schemes. The battle was won under unfavourable conditions and was followed by another hard-fought battle at Pollilur and by the rout of the Mysore troops at Sholingarh a month later. His last service was the arduous campaign of 1782. He died at Madras on April 28, 1783.

See H. C. Wylly, *Life of Sir Eyre Coote* (1922); E. W. Sheppard, *Coote Bahadur* (1956).

(T. G. P. S.)

**COPAIBA** (*Copaiva*), an oleoresin (sometimes termed a balsam) obtained from the trunk of several species of *Copaifera* (family Leguminosae; *q.v.*), native to tropical South America. It is a viscous transparent liquid, occasionally fluorescent and light yellow to pale golden in colour. The odour is aromatic and characteristic, the taste acrid and bitter. Copaiba, insoluble in water but soluble in absolute alcohol, ether and oils, is used in making varnishes and photographic paper, and was formerly used in medicine as a disinfectant.

**COPAL**, a hard lustrous resin, varying in hue from an almost colourless transparent mass to a bright yellowish-brown. When dissolved in alcohol, spirit of turpentine or other suitable solvent it forms a valuable varnish. Copal is obtained from a variety of sources; the term is vaguely used for resins that, though similar in physical properties, differ in their constitution and are altogether distinct as to their source. In Brazil and other South American countries, copal is obtained from the tree *Hymenaea courbaril*, and other species. By far the most important from a commercial point of view is the Zanzibar or East African copal yielded by *Trachylobium verrucosum*. The resin is found in two distinct conditions: (1) raw or recent ("jackass" copal) and (2) ripe or true copal. The raw copal obtained directly from the trees, or found at their roots or near the surface of the ground, does not enter into European commerce. It is sent to India and China where it is manufactured into a coarse varnish. The true or fossil copal is found embedded in the earth over a wide belt of the mainland coast of Zanzibar, on tracts where not a single tree is now visible. It is not found at a depth greater than four feet, and occurs in pieces varying from the size of small pebbles up to masses of several ounces in weight; occasionally lumps weighing four or five pounds have been obtained.

Kauri copal is found in New Zealand, which exports large quantities. It is derived from the kauri pine (*Agathis australis*), and like the East African copal, is found in the earth often far from living trees of this pine.

The dammar resins and the piney varnish of India are occasionally spoken of as copal.

See also RESINS.

**COPALITE** (*Copaline*), also termed "fossil resin" and "Highgate resin," a naturally occurring organic substance found as irregular pieces of pale-yellow colour in the London clay at Highgate hill.

It has a resinous aromatic odour when freshly broken, volatilizes at a moderate temperature and burns readily with a yellow, smoky flame, leaving scarcely any ash.

**COPÁN**, the name of a small department in western Honduras adjacent to Guatemala, and an ancient Maya ruined city. Population of department, mainly rural, was 126,191 in 1960; area 1,237 sq.mi. Despite much hilly to rough land, agriculture is significant and the department produces tobacco amounting to 65% of the national output. It is a relatively important producer of corn, sugar, beans, rice, coffee, swine and poultry. The departmental capital, Santa Rosa de Copán (pop. 7,963), in the eastern part of the department, is the centre of several agricultural districts. The small town of Copán (pop. 1,832), on the Copán river, is near the Guatemalan boundary and the ancient Maya city.

The Maya city of Copán was built during the old empire of the Mayas, which reached its height between A.D. 400 and 600. Excavation of Copán has been carried on especially by the Peabody museum of Harvard university and the Carnegie institution of Washington, D.C. The latter uncovered and restored the beautiful hieroglyphic stairway, two large pyramids serving as bases for temples, spacious courts, carved stone pillars or steles (calendars) and the gigantic sundial, on two hills to the east and west of the city.

(C. F. J.)

**COPE, EDWARD DRINKER** (1840-1897), U.S. zoologist and naturalist known for his work in vertebrate paleontology, was born at Philadelphia, Pa., July 28, 1840, of Quaker parentage. After a brief professorship at Haverford college (1864-67) Cope devoted the rest of his life to exploration, research, writing and editorship. By 1871 he was embarked on his major work, the discovery and description of the extinct fishes, reptiles and mammals

of the western U.S., from Texas to Wyoming. He was one of the last of the zoological explorers of the American west to collect among hostile Indians with a rifle at his side. Even more exciting was the race for priority of discovery of fossil dinosaurs and titanotheres, which led to controversies with colleagues, notably O. C. Marsh (q.v.). Cope's interest in living fishes, amphibians, reptiles and mammals was second only to his special attention to the extinct forms. He was naturally drawn into evolutionary thinking, holding the Lamarckian views then widespread among paleontologists. As editor of the *American Naturalist* he commented and often engaged in controversy on almost every topic of scientific interest of his time. His bibliography includes more than 1,200 published books and papers, ranging from great quarto volumes to half-page editorials. He died at Philadelphia on April 12, 1897.

See H. F. Osborn and H. A. Warren, *Cope: Master Naturalist* (1931). (K. P. S.)

**COPE** (PLUVIALE), a liturgical vestment, a full-length cloak, worn at certain functions in place of the chasuble. See VESTMENTS. ECCLESIASTICAL.

**COPEAU, JACQUES** (1879–1949), French actor, stage director and dramatic coach of widespread influence, was born in Paris on Feb. 4, 1879. After a brief career as an art dealer, he became drama critic for *L'Ermitage* (1904–06) and for the *Grande revue* (1907–10). In 1909, with André Gide, Paul Claudel and others, he founded *La Nouvelle Revue Française* and edited it until 1914. His adaptation of Dostoevski's *The Brothers Karamazov*, written in collaboration with Jean Croué, was staged in 1911. In 1913 he founded the Théâtre du Vieux Colombine, where he produced works from many periods, from Shakespeare and Molière to his contemporary Paul Claudel. Notable in the repertory company were Charles Dullin, Louis Jouvet and Valentine Tessier. His theatre was antinaturalist, and his reconstruction of the Elizabethan apron stage without proscenium arch, and with simple screens to suggest locale was influential both in Europe and in the United States. Emphasizing the play rather than its trappings, he also concentrated on training actors until his company ranked with the Moscow Art theatre of Stanislavski. In 1917 he took his company to New York.

In 1923 Copeau left the Vieux Colombine and moved his acting school to Burgundy. Later he toured Europe with a company of young actors. He was director of the Comédie Française, 1940–41. He died in Beaune on Oct. 20, 1949.

**COPENHAGEN** (Dan. KÖBENHAVN, "Merchant's Harbour"), the capital of Denmark, lies on the eastern coast of the island of Zealand (Sjælland) and on the northern part of the small island of Amager at the southern end of the Sound (Øresund) opposite Malmö in Sweden. Pop. (1960) 721,381. Area 83 sq.km. (32 sq.mi.). Greater Copenhagen consists of 22 independent municipalities (Copenhagen, Frederiksberg, Gentofte and 19 suburban municipalities) covering 583 sq.km. (225.6 sq.mi.) and with a population of 1,321,805. After World War II the growth of population was concentrated in the suburban municipalities. The inner parts of the two central municipalities (Copenhagen and Frederiksberg) were becoming less and less residential. They were completely built up, and their population figures were declining as their inhabitants settled in the suburbs.

The nucleus of the city is on low-lying ground between the sea and the old ramparts and moats, partly incorporated into public parks and gardens and into the citadel. West of the ramparts is a series of small fresh-water lakes, St. Jørgens Sø, Peblinge Sø and Sortedams Sø. Around the original city there are extensive and densely crowded districts (Vesterbro, Nørrebro, Østerbro and Amagerbro) built after the removal of the ramparts in 1872. At the beginning of the 20th century former independent municipalities (the districts of Valby, Vigerslev, Vanløse, Brønshøj and Husum on the Zealand side and Sundby on the Amager side) were incorporated into the city so that its area was trebled, and the municipality of Frederiksberg was completely encircled by Copenhagen. Various parks outside the old ramparts cover 0.6 sq.km. (23 sq.mi.), the largest being Utterslev Mose, Fælledparken and Valbyparken.

The fertile island of Amager produces a large proportion of the vegetables for the capital. It was founded by several Dutch colonists in 1516, and some of its villages, such as Dragør, have a distinctive architecture, costume and dialect. An excellent harbour is provided by the natural channel between the two islands, and communication from one to the other is afforded by three modern bridges, the Langebro, the Knippelsbro and the Sjaellandsbro.

The heart of the city's life is the Raadhuspladsen (Town Hall square) where stands the great town hall, built in 1894–1905. From the square an old crooked shopping street—colloquially called Strøget ("the Sweep")—leads northeast to the former centre of the city, Kongens Nytorv ("King's New square"). This great square, with trees in the centre encircling an equestrian statue of Christian V, was laid out in the 17th century. Buildings of that date include Thotts palace, now the French embassy, and the Charlottenborg palace, now the Academy of Arts, which holds its annual exhibition of painting and sculpture in the adjacent Kunstindustrimuseum (1883). Other buildings in Kongens Nytorv are the Royal theatre (1874) and several great commercial houses. Strøget passes through the oldest parts of the city where the streets still follow the medieval layout. Besides Strøget, other main streets leading to Kongens Nytorv are Bredgade and Store Kongensgade from the north and Gothersgade from the west. A narrow arm of the harbour (Nyhavn) lined with picturesque old gabled houses leads to Kongens Nytorv from the sea. From the southern end of the square a street called Holmens Kanal winds past the National bank to the Holmens Kirke (the naval church), originally erected as an anchor smithy by Frederick II but consecrated by Christian IV, with a chapel containing the tombs of the great admirals Niels Juel and Peder Tordenskjold.

Holmens Kanal crosses a bridge to Slotsholmen ("Castle Islet"), which is divided from the mainland by a narrow strip of water. It contains the Christiansborg palace, originally built during 1737–45 by Christian VI on the site of an older castle founded by Bishop Absalon in 1167. Twice destroyed by fire, in 1794 and 1834, the royal palace was rebuilt after 1907 for use on state occasions. After 1918 it was occupied by parliament, the supreme court and the foreign office. The palace chapel (1826) is adorned with works by the Danish sculptors B. Thorvaldsen and H. V. Bissen. In adjacent buildings are the central government offices. The exchange (Børsen), on the quay to the east, is an ornate, gabled building erected during 1620–40 and surmounted by a remarkable spire formed of four entwined dragons' tails.

Southeast of Christiansborg is the arsenal (Tøjhuset), with its collection of armour, and the Royal library (national library) in which are housed R. Rask's famous Persian manuscripts and a unique Mongolian and Tibetan collection. In an adjacent building is the Arnamagnean collection of old Norse-Icelandic documents. The Thorvaldsen museum (1839–48), on the northwest corner of Slotsholmen, has an open court containing the sculptor's tomb, and most of his original works are in this museum.

On the mainland, immediately west of Slotsholmen, is the Prinsens palace, the residence of Christian V and Frederick VI when they were crown princes, which is now the National museum. This consists of six sections: the prehistoric collections, the Danish historical and folk museums, the ethnographical and the numismatic collections and the collection of classical antiquities. The collection of prehistoric Danish finds, in particular those of the Bronze Age, is most remarkable. In Nytorv ("New Market") is the former town hall (1815), now the city court, to the north of which is Gammeltorv ("Old Market"), the main square of the medieval town. From there an old street leads to the Vor Frue Kirke ("Church of Our Lady"), the cathedral church of Copenhagen. This church, on a 12th-century site, was rebuilt after the bombardment of 1807 and is adorned with marble works by Thorvaldsen, the most famous of which is the colossal statue of Christ.

Just north of the Vor Frue Kirke is the university (until 1933 the only one in Denmark), founded by Christian I in 1479, although its constitution dates from 1788. The modern buildings date from 1836 and include the university library. This has a new section in the modern University park in the Østerbro district where are also the departments of medicine, dental surgery and pharmacy,

among others. Opposite the old university is St. Petri church, built in quasi-Gothic style with a spire 251 ft. high and after 1585 used as a parish church for the German residents of the city. A short distance to the northeast, in Köbmagergade, is Trinity church whose round tower (117 ft.), considered to be unique in Europe, was formerly used as an observatory. Toward Slotsholmen, Köbmagergade opens into the Højbro-plads which contains an equestrian statue of Bishop Absalon and from which a bridge goes across a narrow arm of the harbour to Slotsholmen.

The area from Kongens Nytorv and Gothersgade, northeast to the moated citadel (1662-63) which guards the harbour, includes the palace of Amalienborg, the castle and gardens of Rosenborg and the Frederikskirke or Marble church. The last named was begun in the reign of Frederick V (1749) but was left unfinished until 1874, when it was purchased by a wealthy banker, who added the conspicuous dome. The four rococo palaces, of uniform design, encircling the neighbouring Amalienborg-plads, have been the residence of the king and the royal family from 1794.

Southwest from the citadel extends the line of parks on the site of the former fortifications, skirted on the inner side by wide boulevards, Østervoldgade, Nørrevoldgade, Vestervoldgade and, close to and parallel with Vestervoldgade, H. C. Andersens boulevard. The botanical gardens (1874) contain an observatory with a statue of Tycho Brahe; and the Rosenborg park, on the opposite and inner side of Østervoldgade, contains the palace of Rosenborg (1610-34), an irregular building in Renaissance style with a high, pointed roof flanked by four unequal towers. It is now a museum with fine collections of furniture, Venetian glass, oriental carpets and silver, including the famous silver drinking horn of Oldenburg (1474) and the crown jewels. The Vestervoldgade and H. C. Andersens boulevard flank the Raadhuspladsen from where several main streets radiate to vast residential quarters. H. C. Andersens boulevard runs across the harbour on the Langebro bridge to residential quarters on the island of Amager, its extension leading to Kastrup, the Copenhagen airport. The boulevard skirts the Tivoli pleasure garden and passes the Ny-Carlsberg Glyptotek with its very fine collection of old and new art. The quarter of Christianshavn skirts the harbour to the south and lies within the fortifications. It contains the Vor Frelzers Kirke ("Church of Our Saviour"), dedicated in 1696, with a curious 284-ft. steeple. From the western end of the Raadhuspladsen, the Vesterbrogade leads to the Central station, where there is a modern business quarter with an air terminal and hotel 21 stories high as its central point.

The western quarter contains the Frederiksberg park, with its palace, erected in the reign of Frederick IV and used as a military school. The park also contains a zoological garden. From H. C. Andersens boulevard, main streets lead to the modern northwestern residential districts, Brønshøj, Husum and Bispebjerg with the impressive Grundtvig church built during 1921-40 to commemorate the founder of the Danish folk high schools.

Copenhagen is the centre of several important learned societies, including the following: the Royal Danish Academy of Sciences

and Letters, founded in 1742; the Royal Society of Nordic Antiquaries (1825), which is concerned with northern and Icelandic archaeology; the Royal Academy of Fine Arts, founded by Frederick V in 1754; the two Carlsberg foundations, established in 1876 and 1902 by the brewers J. C. and C. Jacobsen, which promote research and foster art. Among educational institutions besides the university may be mentioned: the Royal Veterinary and Agricultural school established in 1773 and adopted by the state in 1776; the Technical university (1829); the Royal Academy of Music (1867); the dental college (1888); the high school of pharmacy (1892); the Technological institute (1908); and a high school of commerce (1924).

Churches other than Lutheran include: the Reformed church, founded in 1688 and rebuilt in 1731; the Roman Catholic church of St. Ansgarius, consecrated in 1842; and the Jewish synagogue in Krystalgade, which dates from 1833. Of the monastic buildings of medieval Copenhagen, traces are preserved in the names of the streets. The Franciscan establishment gives its name to the Graabrødretorv or Grey Friars' market; and St. Clara's monastery, the largest of all, which was founded by Queen Christina, is still commemorated in the Klareboder or Clara buildings.

**Commerce and Industry.**—Copenhagen is by far the most important commercial town in Denmark. Most of the country's foreign trade passes through the capital, while the transit trade is considerable. Copenhagen is, moreover, the headquarters of nearly all the steamship companies of Denmark. The harbour is mainly contained in the narrow strait between the outer Sound and its inlet, the Kalvebod Strand. Trading facilities were improved by the construction in 1894 of the Frihavn ("free port") at the northern end of the town which contributed largely toward the position of Denmark as an emporium of Baltic trade. The area of the free port is 0.66 sq. km. (0.25 sq. mi.) and that of the customs ports, 2.76 sq. km. (1.07 sq. mi.). The harbour has a total water area of 13.15 sq. km. (5.08 sq. mi.). More than 30,000 ships arrive at Copenhagen annually with more than 15,000,000 net registered tonnage.

Copenhagen is connected by rail, including train ferry, with Oslo and Stockholm to the north, and by rail with practically all the principal cities to the south. The Copenhagen airport (6½ mi. from the city centre) is one of the most important in northern Europe. International and intercontinental routes include one to Los Angeles via Greenland and another to Tokyo via the north pole.

The chief imports are raw materials, machinery and other equipment. The principal exports are agricultural products, machinery (e.g., marine engines, cranes, refrigerators, dairy machinery, cement-making apparatus, made in the city), iron and steel goods and chemicals. Nearly half the population of Copenhagen is engaged in industries and handicrafts including shipbuilding, the manufacture of diesel engines and machinery, canning and brewing (Carlsberg and Tuborg beer). Special mention may be made of the Royal Copenhagen porcelain factory, the Bing og Grøndahls china factory and the Georg Jensen hand-wrought-silver works.

**History.**—Excavations show that the site of the inner town of Copenhagen has been inhabited for 6,000 years. About the year 1000 the fishing hamlet Havn was known as a place of commercial and strategic significance because of its position near one of the best natural harbours in northern Europe on one of the principal European trade routes. In 1167 Bishop Absalon of Roskilde, the foster brother of King Valdemar I, built a castle to protect the citizens against hostile fleets. The ruins of this castle can be seen in the cellars of the castle of Christiansborg. In 1254 the first civic charter was granted by the bishop of Roskilde. The city played an important role in the wars with the Hanseatic league and was several times attacked. It remained in the possession of the bishops of Roskilde till 1417 when it passed to the crown, which, in 1443, granted the city a royal civic charter. Two years later the city became the residence of the king. In 1479 the university was founded, and soon after the naval base and naval shipyards were established.

During the years of the civil and religious wars between 1553 and 1536 the city was often attacked. In the reign of King Christian IV (1588-1648) foreign trade grew immensely and

J. ALLAN CASH

CONCERT HALL (1956), IN TIVOLI GARDENS, COPENHAGEN, DEN.

magnificent castles and other buildings were erected. In the wars with Sweden (1657–60) the whole country with the exception of Copenhagen was occupied and for two years (1658–60) the city was besieged in vain by the Swedish king Charles X Gustavus. After the peace of Copenhagen (1660) the king yielded to the demands of the citizens for the abolition of the privileges of the nobility, and in 1661 he granted royal privileges to Copenhagen including the establishment of a city council of 32 men elected by the leading citizens.

Both in 1728 and in 1795 great fires reduced considerable parts of the city to ashes. To prevent an eventual Danish closing of the Baltic a British fleet attacked Copenhagen in 1801 under the command of Sir Hyde Parker and Lord Nelson (see *Battle of Copenhagen*, below). In 1807 the capital was bombarded for three nights by the British in order to force the Danes to give up the Royal Danish Navy to England. On March 21, 1848, the city council went to the king to demand a free constitution for the country and this constitution became law in 1849. It contained a clause which declared "the right of the local governments, under the supervision of the state, to manage their own affairs." This clause gave rise to the new city statutes of 1857, which attained their final form in 1938.

In World War II Copenhagen was occupied by German troops from April 9, 1940, to May 5, 1945. The Danish resistance movement grew up during 1941. The Royal Air Force bombed the main shipyards and completely destroyed the headquarters of the Gestapo in March 1945 and the capital was liberated by British troops in May.

(ED. H.)

**Battle of Copenhagen.**—On Dec. 16, 1800, Russia, Prussia, Denmark and Sweden, backed by France, formed a league to resist a British claim to the right of search at sea. Britain retaliated by sending a fleet to the Baltic on March 12, 1801, under Sir Hyde Parker, Lord Nelson being his second in command (see NELSON, HORATIO NELSON, Viscount). Denmark was sent an ultimatum to withdraw from the league. In the event of refusal, Parker was ordered to destroy or neutralize the country's naval strength. Denmark was defiant, and Copenhagen was put into a state of defense. On hearing the news, Nelson urged an immediate attack, recommending as an alternative that part of the fleet should advance up the Baltic to attack the Russian fleet. Parker was unwilling to venture up the Baltic with Danish forces unsubdued behind him or to divide his force, and finally agreed to an immediate attack on Copenhagen.

After the fleet entered the Sound it was engaged by the batteries of Kronborg castle, ineffectively because the Swedes did not second their opposition from the eastern side. The fleet brought up under the shelter of Hven on March 30, and the operation was planned. Because of the shallow water in the approaches to Copenhagen, the heavier ships would take no part in the direct attack on the floating batteries and forts. This was entrusted to Nelson with 12 sail of the line and smaller vessels. The Danish position was particularly strong at the northern end where the heavy guns of the Trekroner battery were located. Nelson's plan was first to advance his force to the southern end of the Middle Ground, the great shoal opposite Copenhagen; then, when the wind changed, to move northward along the Danish line, blasting it as he went. Parker, with the heavier ships, would lie off the entrance to the harbour, ready to prevent any sortie from seagoing squadrons.

On April 1, 1801, Nelson successfully navigated his force from north to south of the Middle Ground. Early on April 2 the wind changed and he went into battle, advancing along the Danish line, the frigates leading under Capt. Edward Riou. Three ships went aground on the shoal and Riou was left to bombard the Trekroner with only a light squadron. For several hours fighting was severe, and so critical did Nelson's position seem that Parker signaled him to disengage. Nelson took no notice (this being the occasion when he put his telescope to his blind eye), but Riou with his frigates withdrew from his exposed position and was killed in the process. Early in the afternoon Danish fire slackened, and Nelson sent a flag of truce ashore to the crown prince, regent of Denmark. Firing ceased and negotiations were begun for a formal

armistice, made easier for Denmark as a result of the assassination of the emperor Paul of Russia, the most forceful member of the league. Both sides had suffered; there were about 900 English and 1,700 Danish casualties. Nelson was in charge of negotiations and he officially replaced Parker on May 5. A convention was agreed in June, which ended the immediate campaign.

(ED. H.)

**COPEPODA**, one of the subclasses of the Crustacea (*q.v.*), the members of which, for the most part of microscopic size, are abundant in the sea and in fresh waters.

**Importance.**—They form one of the most important constituents of the plankton and it would be difficult to find a sample taken with the tow net in any part of the world that did not contain some representatives of the group. The bottom-living (benthic) species, which have been less studied, are not so numerous as individuals but probably include more species than the open-sea (pelagic) forms. A ten-quart pail of wash water from the sand of Katama bay, Martha's Vineyard, yielded 800 sand-dwelling copepods distributed among 25 species, with one exception (Cyclopoida) all Harpacticoida (see below). A large number of Copepoda are parasitic on other aquatic animals of all classes; these exhibit a wide range of modification in structure and life history. Copepods, in the economy of the sea, rank perhaps first as food for other marine animals because of their abundance; *Calanus* species, particularly *C. finmarchicus*, are an important link in many marine food chains. (See also MARINE BIOLOGY; PLANKTON.)

**Structure and Natural History.**—The typical free-swimming Copepoda have usually a somewhat pear-shaped body, divided into segments (somites) and narrowing behind to end in a caudal (tail) fork. There is no distinct carapace (a bony or horny dorsal shield), although one or two of the body somites are coalesced with the head. There are four or five pairs of two-branched, oarlike, swimming "feet." The unbranched antennules are generally large and many-jointed, the antennae smaller, sometimes two branched, and both are used in swimming. The mandibles are often of very primitive structure, the two-branched head appendage (palp) retaining the form and to some extent the function of a swimming "foot." The unpaired or larval (nauplius) eyespot is usually present (paired eyespots are not developed in the typical Copepoda). The eggs are usually carried by the female, cemented together into one or a pair of masses (ovisacs) attached to the genital openings. The young are hatched, as a rule, in the nauplius stage and attain the adult form by the successive addition of somites and appendages without any very sudden change. The antennules, antennae and mandibles may retain in the adult copepod, more nearly than in any other Crustacea, the form they have in the nauplius stage.

The parasitic habit has been acquired in the evolution of many unrelated families of Copepoda and the modifications of structure and of life history to which it has led are correspondingly diversified. In some parasites the power of swimming has been retained and the general form does not differ greatly from that of free-living species, the mouth parts only becoming modified for suck-

FIG. 2.—*LERNAEA BRANCHIALIS*  
One of the Lernaepodoida, a parasite found on the gills of the cod and other fishes. Above are the branched root-like processes of the head region, which are buried in the tissue of the host, and below the body proper are the two intertwined tubular egg masses

are species of *Pennella*, parasitic on whales, that sometimes exceed a foot in length.

**Branchiurans, Problematical Relatives.**—A small group of Crustacea ectoparasitic (parasites on the outside) on fish, both fresh-water and marine, and heretofore considered an order of Copepoda, the Branchiura (carp or fish lice), have been elevated to the rank of subclass, comprising an order Arguloida, named after the typical genus *Argulus*. Branchiurans differ from copepods in having paired compound eyespots, which, although characteristic of many Crustacea are not possessed by copepods; in lacking an ovicel in the female, the eggs being deposited on some suitable surface (a few copepods shed their eggs directly into the water); and in having the larvae, which much resemble a partly developed *Caligus*, well developed when hatched. Generally speaking, the broad, flat, oval body of branchiurans is not unlike that of some copepods. The segmentation of their body corresponds closely to that of the copepods; the appendages also are similar in number and grouping, but differ in having on some of the legs of some species an inward extension of the exopodite (the lateral branch of the two-branched appendage) not found in the Copepoda. On the underside of the head there is, in most of the species, a pair of suckers which are shown by their development to be modified maxillae (jawlike mouth parts). In front of the mouth in the genus *Argulus* is a sharp protrusible spine connected with a supposed poison gland.

**Classification.**—As the parasitic Copepoda do not constitute a single order and the details of the distribution of many of them among the free-living families have still to be worked out, the classification of the Copepoda is not yet settled. A working classification, however, recognizes seven orders: the Calanoida, almost exclusively planktonic; the Harpacticoida, for the most part bottom living; the Cyclopoida, both free swimming and parasitic; and the Notodelphyoida, Monstrilloida, Caligoida and Lernaepodoida, exclusively parasitic.

(W. T. C.; W. L. St.; X.)

**COPERARIO, JOHN** (real name, COOPER) (c. 1575–1626), English violist, lutenist and composer, especially of music for viols. Sometime before 1604 he went to Italy and, as a result, Italianized his surname and became influenced by the Italian manner of playing and composition. After returning to England he became musical tutor to the children of James I and to Henry and William

Lawes. He was later appointed royal lutenist and composer. He died in London in 1626.

Coperario composed songs and music for masques but is most famous for his fantasias for viols. These fantasias are more sectionalized than those of his contemporaries and show great contrapuntal ingenuity. Some are scored for "violins," an almost unique requirement in English music of this period. He published two collections of compositions (1606 and 1613) and contributed two anthems to Sir William Leighton's *Tears or Lamentations of a Sorrowful Soul* (1614).

(A. D. F.)

**COPERNICUS, NICOLAUS** (MIKOLAJ KOPERNIK) (1473–1543), Polish astronomer, propounded the Copernican theory which revolutionized planetary astronomy and laid the foundation stone for modern developments. He was born on Feb. 14, 1473, at Torun on the Vistula river where his father was a merchant of some social standing. In 1491 Copernicus went to the University of Cracow. There he came under the influence of the mathematician Wojciech Brudzewski (1445–97), a supporter of the geocentric system of Ptolemy, who is believed to have awakened his genius. Copernicus probably returned home in 1494, and his maternal uncle Lucas Waczenrode, elected bishop of Ermeland (Warmia) the same year, wished to confer on his nephew a canonry of Frauenburg (Frombork). He thus sent him for further training in Italy and in 1497 Copernicus became a student in the *Natio Germanorum* at Bologna. For three and a half years he studied Greek, became acquainted with the writings of Plato, and in due course was closely associated as friend and assistant with the astronomer Domenico Novarra of Ferrara (1454–1504) in spite of their disparity of age. Copernicus was thus encouraged to observe the heavens and his first recorded observation (an occultation of Aldebaran) was made on March 9, 1497. Copernicus went to Rome in the spring of 1500, the year of the great jubilee, and there he gave a course of lectures in mathematics. He had been elected (by proxy) a canon of Frauenburg in 1497 and in 1501 he returned to take his seat on the cathedral chapter. This year saw him return again to Italy, under special leave of absence, to continue his studies. He entered the University of Padua where, enrolled in the register of Polish students, he studied both law and medicine and, except for a short break in 1503 when he was granted the degree of doctor of canon law at Ferrara on May 31, he spent almost four years in Padua. Copernicus returned to Poland in 1503 and, after his stay in both Bologna and Padua, can be said to have been in possession of all the knowledge of the day in mathematics, astronomy, medicine and theology. On his return he revisited Cracow and later acted as adviser to his uncle, the powerful bishop of Ermeland, until the latter's death in 1512. Copernicus remained at Frauenburg acting as representative of the cathedral chapter, his medical skill being used especially for the poor. His fame as an earnest student of astronomy spread and in 1514 he was invited to give his opinion on reform of the calendar which was then being considered by the Lateran council, but he refused to express any firm views for he was of the opinion that the positions of the sun and moon were not known with sufficient accuracy to permit of a proper reassessment of the position.

Soon after his return from Italy, Copernicus appears to have planned a program of astronomical work. Although he carried out no extensive program of observations, he made such measurements as would enable him to redetermine the elements of the orbits of the sun, moon and planets. He published 27 such observations made over the years 1497–1529 and a few others have been found entered in books from his private library.

After settling in Frauenburg Copernicus became increasingly dissatisfied with the Ptolemaic system of astronomy. He was not alone in this dissatisfaction; indeed he himself said that the many divergent views prevalent in his day gave him cause for profound thought. These difficulties had arisen as the accumulated observations on the position of the sun, moon and planets had made it necessary to elaborate the arrangement of deferents and epicycles which the Ptolemaic system contained. It was therefore an increasingly laborious task to compute the future positions of these bodies and, of course, much of the elegance of the Ptolemaic hypothesis was lost. Ptolemy's system contained not only some

original work but also a synthesis of the views of previous Greek philosophers and was based on a purely geocentric basis. By the 16th century this geocentric idea had become not only firmly entrenched in astronomical thought but also had the virtual standing of an article of faith. Although certain Greek philosophers had, as far back as the third century B.C., suggested that the sun and not the Earth was the centre of the universe, their ideas had not been developed. However Copernicus concluded that, in view of the plethora of epicycles necessitated by the Ptolemaic system so that it might still account for the observed motions of heavenly bodies, it must contain some basic error. In consequence he read many original Greek authors and discovered that heliocentric hypotheses had been suggested. The idea of a moving Earth seemed absurd at first but when Copernicus used this assumption he found that a much simpler and aesthetically superior system resulted even though, as might be expected, he still believed that the planets moved with uniform circular motion. After many years of labour he became convinced of the truth of his new ideas, but made no attempt to publish them. It was only the efforts of his friends and, more particularly, those of his pupil and disciple Georg Joachim Rhäticus (1514-76), who studied with him for two years, that finally resulted in the publication in 1543 of the great *De revolutionibus orbium coelestium*. Although not widely accepted at once, the heliocentric views of Copernicus, as expounded in this work, in due course exerted a vital influence on astronomy. Thomas Digges (?-1595) appears to have been the first English supporter of the Copernican teachings, and the work of Kepler and Galileo helped, of course, to bring general acceptance.

However in 1530 Copernicus circulated a manuscript, the *Commentariolus*. This was, in effect, a summary of his ideas but it contained no diagrams or calculations. Lectures on the principles which the manuscript expounded were given in Rome by Johann Albrecht Widmanstadt, Pope Clement VII approved and a formal demand for publication was made. In 1540 Rhäticus, who himself had published an exposition entitled *Narratio prima de libris revolutionum*, was permitted to take the complete manuscripts to Nürnberg for printing. Because of opposition from Luther, Melancthon and others, Rhäticus left Nürnberg and went to Leipzig. He passed on the task of publication to Johannes Schöner and Andreas Osiander. The latter corresponded with Copernicus but, apparently fearing severe criticism of views which considered the Earth as having an annual motion around a stationary sun, Osiander inserted on his own responsibility a preface which emphasized that the heliocentric hypothesis was only a convenient means for simplifying planetary computation. A careful examination of the text makes it clear, however, that Copernicus himself really believed that the heliocentric theory, which originally he had viewed with disfavour, was a true picture of the system of the sun and planets. He placed the orbits of Mercury and Venus next to the sun, the Earth followed with the moon circling around it, then came the orbits of Mars, Jupiter and Saturn with the sphere of fixed stars outside. The *De revolutionibus* was written in six sections or books, the first proving that the earth is spherical and moving, as well as containing some remarks on spherical trigonometry and a catalogue of stars. In the second the ecliptic is discussed; the third deals with precession and the apparent motion of the sun. The fourth book concerns the moon and in the fifth and sixth the planets are discussed. The whole work was not completed until 1543 and is believed to have been brought to Copernicus on his deathbed. Copernicus died at Frauenburg on May 24, 1543.

Copernicus also published, in 1509, a Latin version of Greek epistles by Theophylact (fl. A.D. 610-629), and an exposition of principles of currency reform for certain Polish provinces was written in 1525 but not published until 1816 at Warsaw.

See **ASTRONOMY: History of Astronomy**; see also references under "Copernicus, Nicolaus" in the Index volume.

**BIBLIOGRAPHY.**—The only contemporary biography of Copernicus, which was written by Rhäticus, has perished. Various biographies have been published, especially in connection with the quatercentenary of 1543. These are: A. Armitage, *Copernicus, Founder of Modern Astronomy* (1939); S. P. Mizwa, *Nicholas Copernicus*, Kosciuszko Foundation (1943); Victoria University College, Wellington, N.Z., *Quadracentennial Addresses* (1943); J. Rudnicki, *Nicholas Copernicus*,

*Copernicus Quatercentenary Celebration Committee* (1943). Other works are: L. Prowe, *Nicholas Copernicus*, 3 vol. (1883-85); E. Rosen (ed.), *Three Copernican Texts: Commentariolus, Letter Against Werner and Narratio prima de Rhäticus* (1939). A facsimile text of *De Revolutionibus* and a reprinted text (Latin) with notes were prepared by F. Kubach (1944). (Cn. A. R.)

**COPIAPÓ**, capital of the north Chilean province of Atacama (q.v.), is located about 35 mi. from the coast in the fertile Copiapó river valley, an irrigated oasis which has been farmed at least since the Inca period. Pop. (1960) 37,224 (mun.). It is perhaps the most attractive of the northern cities with architecture that retains the provincial 19th-century style; the buildings are not original but were rebuilt after destruction by the serious earthquakes of 1819, 1822, 1851, 1918, 1922 and 1939. Settled about 1540 on orders of Pedro de Valdivia, the community was elevated to *villa* status in 1744, at which time it became San Francisco de la Selva de Copiapó. The settlers of Copiapó explored much of the nearby Atacama desert (q.v.). Their discovery and development of copper deposits and Juan Godoy's discovery in 1832 of the rich silver lode near Chañarcillo resulted in the town becoming a significant mining and political centre. Its position and wealth were also exemplified by the Caldera and Copiapó railway (one of the first in South America), built in 1850-51 by the American William Wheelwright (q.v.).

Local power and prestige, which had gradually eclipsed between 1875 and 1925, was fostered anew by copper mining. A local boon has been the construction and operation (1951) of the government's Paipote copper smelter, where there is a good mining school.

Railway and all-weather roads connect the city to the port and bathing resort of Caldera and to the adjacent provinces and Santiago. A road also connects with Tinogasta, Arg. The city has an airport. (J. T.)

**COPING**, in architecture, a capping or covering for the top of a wall to prevent the entrance of water. In those countries and times in which parapets were common, coping design became of great importance, especially in Gothic work, where copings were usually of stone with a steeply sloped, and sometimes molded, profile. Copings may be made of stone, brick, tile, slate, metal, wood or thatch. They are usually sloped so as not to hold water, and projected beyond the face of the wall they cover in order to prevent the wall below from becoming saturated.

**COPLAND, AARON** (1900—), U.S. composer whose great achievement is a distinctive musical characterization of American subjects in an expressive modern style, was born in Brooklyn, N.Y., Nov. 14, 1900. He studied harmony and counterpoint in New York with Rubin Goldmark (1917-21), and free composition and orchestration with Nadia Boulanger (1921-24) in Paris. His first published work, *The Cat and the Mouse* for piano (1919), is impressionistic in style. Upon his return to America, he wrote a symphony for organ and orchestra (1924). Much more advanced was his *Music for the Theater* for small orchestra (1925), employing asymmetric rhythms with striking effect. On Jan. 28, 1927, Copland was soloist in his piano concerto with the Boston Symphony orchestra under S. Koussevitsky, which produced a sensation because of its outspoken jazz idiom.

Then followed works of distinct American connotations. *Lincoln Portrait* for speaker and orchestra (1942) embodied thematic materials from contemporary songs; the ballet *Appalachian Spring* (1944) also utilized American tunes. Mexican folksongs form the materials of the tone poem *El Salón México* (1936), and Cuban rhythms permeate the *Danzón Cubano* for two pianos (1942). The ballets *Billy the Kid* (1938) and *Rodeo* (1942) make use of western cowboy tunes. In all these pieces the folksong materials are reworked in a highly individual manner. His operas *The Second Hurricane* (1937) and *The Tender Land* (1954) are also based on American subjects.

Much more austere are Copland's instrumental works; of these, the most important are *Symphonic Ode* (1929; revised in 1955); *Short Symphony* (1933; also arranged as a sextet for clarinet, piano and string quartet); and *Third Symphony* (1946), in which a quasi-atonal tension is enhanced by extremely mobile rhythms. In his *Quartet for Piano and Strings* (1950) Copland applies a

thematic series of 12 different notes. His *Piano Variations* (1930) and *Piano Sonata* (1941) are significant as examples of pure constructivism. The song cycle *Twelve Poems by Emily Dickinson* (1950) introduces a vocal line in widely disjunct intervals sustained in a framework of inherent tonality.

Copland wrote incidental music for the play *Quiet City* (1939) and for the films *Of Mice and Men* (1939), *Our Town* (1940), *The Red Pony* (1948) and *The Heiress* (1949); he also is the author of *What to Listen for in Music* (1939), *Our New Music* (1941), *Music and Imagination* (1952) and *Copland on Music* (1960). He traveled widely as conductor and lecturer in America, Europe, Russia and the far east.

See A. Berger, *Aaron Copland* (1953); J. F. Smith, *Aaron Copland* (1955).

**COPLEY, JOHN SINGLETON** (1738–1815), American-British painter, best among the pre-Revolutionary painters, was born (probably in Boston) on July 3, 1738. In 1748 his widowed mother married Peter Pelham, the limner and engraver, and Copley thereby had direct contact with painting, engraving and music. At 15 Copley signed an oil portrait and his only known engraving. He soon mastered miniature painting and pastel, with admirable results.

Copley's final decade in America (1764–74) was filled with portrait commissions and marked by two events important for him. In 1766 he sent "The Boy With the Squirrel" (privately owned) to London, where it received discriminating praise. In 1769 he married Susannah Clarke, daughter of a rich Boston merchant. His mature American style, exemplified in "Jacob Hurd" (Cleveland museum) and "Mrs. Thomas Boylston" (Harvard university), manifests strong drawing and rich colour in impressive designs.

A stay in Italy (1774–75) broadened his style. Settling in London, he succeeded (1778) in transcending portraiture with the notable "Watson and the Shark" (Boston museum). Elected to full membership in the Royal Academy (1779), he had a decade of fame and prosperity, in spite of several quarrels, from "The Death of Chatham" (National gallery, London) to "The Siege of Gibraltar" (Guildhall, London). His earlier painstaking technique was now lightened by considerable fluency. Thereafter skill and fortune declined; in his last years he experienced financial difficulties and suffered ill-health.

Copley died in London, Sept. 9, 1815.

**BIBLIOGRAPHY.**—J. T. Flexner, *John Singleton Copley* (1948); *Letters and Papers of John Singleton Copley* (1914); B. N. Parker and A. B. Wheeler, *John Singleton Copley: American Portraits* (1938).

(VL. B.)

**COPPÉE, FRANÇOIS** (1842–1908), French author, achieved success with his play, *Le Passant* (1869), and as a poet of the Parnassian school, but later became known as the *poète des humbles*. He was born in Paris, Jan. 26, 1842; held a number of posts, including that of archivist of the Comédie Française (1878–84); was elected to the Académie Française (1884); and died in Paris, May 23, 1908. From 1867 he published poems, plays, contes and novels, and achieved popularity by expressing commonplace emotions memorably. His reconversion to Roman Catholicism, described in *La Bonne Souffrance* (1898), and the part he played with the extreme nationalists in the Dreyfus case, added to his fame, which has not, however, been sustained.

See biographies by M. F. A. de Lescure (1889) and L. Le Meur (1932).

**COPPER**, one of the most useful of the nonferrous metallic elements, was discovered and first used by Neolithic man during the late Stone Age. The exact time of this discovery will probably never be known, but it is believed to have been about 8000 B.C. Copper is found in the free metallic state in nature and this native copper is the material which Neolithic man used as a substitute for stone. From it he fashioned crude hammers and knives and, later, other utensils. The malleability of the material made it relatively simple to shape implements by beating the metal into the desired shape. Pounding hardened the copper so that keener and more durable edges resulted and the bright reddish colour of the metal and its everlasting qualities made it highly prized.

The search for copper during this early period led to the discovery and the working of deposits of native copper. Sometime after 6000 B.C. the discovery was made that the metal could be melted in the campfire and cast into the desired shape. Then followed the discovery of the relation of metallic copper to copper-bearing rock, and the possibility of reducing ores to the metal by the use of fire and charcoal. This was the dawn of the metallic age and the birth of metallurgy. (See METALLURGY: History.)

The early age of copper probably had its greatest development in Egypt. As early as 5000 B.C. weapons and implements left in graves for the use of the dead were of copper. Definite records have been found of the working of copper mines on the Sinai peninsula by King Snefru about 3800 B.C., and the discovery of crucibles at these mines indicates that the art of extracting the metal included some refining. The art had also developed to the point where copper was hammered into thin sheets and the sheets in turn formed into pipes and other objects. During this period bronze made its first appearance. The oldest piece of this material known is a bronze rod found in the pyramid of Medum, the date of origin being generally accepted as about 3700 B.C.

Bronze, an alloy of copper and tin, possesses qualities of hardness and toughness superior to copper. This alloy was generally used as a material from which to fashion weapons and objects of art. The period of its extensive and characteristic use has been designated as the Bronze Age. From Egypt the use of bronze rapidly spread over the Mediterranean area; to Crete in 3000 B.C., to Sicily in 2500 B.C., to France and other parts of Europe in 2000 B.C. and to Britain and the Scandinavian area in 1800 B.C.

About 3000 B.C. copper was produced extensively on the island of Cyprus. These copper deposits were so great and so highly prized that control of the island passed successively to the Egyptians, Assyrians, Phoenicians, Greeks, Persians and the Romans. The Roman supply of the metal came almost entirely from that island, and the material was known as *aes cyprium* ("ore of Cyprus"), which was shortened to *cuprium* and later corrupted to *cuprum*. From this name comes the English name copper. The first two letters of the Latin name constitute the chemical symbol Cu.

When copper and bronze were first used in Asia is not known. The epics of *Shu Ching* mention the use of copper in China as early as 2500 B.C. but nothing is known of the state of the art at that time or of the use of the metal prior to that time. Bronze vessels of great beauty made during the Shang dynasty, 1765–1122 B.C., have been found, indicating an advanced art. The secret of the source of the metals, however, is probably forever locked in the sacred graves of the early Chinese.

The copper age in the Americas probably dawned between A.D. 100 and A.D. 200. Although native copper was mined and used extensively, some bronze made its appearance in South America, and the art developed slowly until after the arrival of Columbus and other explorers. Both North and South America passed more or less directly into the Iron Age.

As man learned to fashion his weapons from iron and steel, copper began to assume another role. Being a durable metal and possessed of great beauty, it was used extensively for household utensils, for marine uses, water pipes and other purposes where resistance to corrosion was important. The unusual ability of this metal to conduct electric current accounts for its greatest use during the 20th century.

## OCCURRENCE

Copper in nature occurs widely distributed and in many unusual places. It is found in many rocks and soils as well as in oceanic clays and river silts, in the ashes of seaweeds and many other plants, in the human liver and in many Mollusca and Arthropoda such as snails and spiders. It is believed that in plant life the metal is present because of mechanical storage, but that in Mollusca it forms the nucleus of a respiratory protein, and that in Arthropoda it is the nucleus of hemocyanin, which plays the same role as ferruginous hemoglobin in the red-blooded animals. Copper is also reported present in the sun and in many corals of the sea.

**Ores.**—The ores of copper are in general classified into three groups: the native coppers, the sulfide ores and the oxide ores.

Although commercial deposits of copper ores occur in every continent, four general areas contain about 90% of the world's known reserve. These areas are: (1) the Rocky mountain and

SPRAY OF NATIVE COPPER FROM THE LAKE SUPERIOR REGION, UPPER PENINSULA, MICHIGAN

Great Basin area of the United States; (2) the west slope of the Andes mountains in Chile and Peru; (3) the central plateau of Africa in the Republic of the (former Belgian) Congo and Northern Rhodesia; (4) the Precambrian shield area of central Canada and its extension into northern Michigan. These areas have been listed in the order of their importance, based on past production tonnages. The greatest known reserve of copper ore

supply for many years. Of the major producing areas of the world, the porphyry copper deposits account for the greatest tonnage of metal. These are disseminated deposits in which the copper minerals are more or less uniformly scattered through a large body of rock. The copper minerals in the upper portion of the deposits are in general oxides, but are sulfides in the lower levels. The host rock is porphyry, schist or other rock; but since the first deposits discovered were in porphyry, the deposits have been named "the porphyry coppers." One of the largest deposits in the world is located at Bingham Canyon, Utah.

The great deposits of the Republic of the Congo and Northern Rhodesia are second in importance only to the porphyry coppers. These deposits are also disseminated, but are characterized by sharp delimitations by barren wall rock. The copper content of the ore is higher than the porphyry coppers, and in general the oxidized zones have been extensive.

The mines at Butte, Mont., had produced by the second half of the 20th century more copper than any other single area in the world. The copper minerals in these mines occur in well-defined veins and are chiefly chalcocite, bornite and enargite.

The large copper-ore deposits in eastern Canada are complex and

TABLE I.—General Classification of the Ores of Copper

Name	Formula	% Copper (approximate)
Native copper ore:		
Native copper	Cu	99.9
Sulfide ores:		
Chalcocite	Cu <sub>2</sub> S	79.9
Covellite	CuS	66.5
Chalcopyrite	CuFeS <sub>2</sub>	34.6
Bornite	Cu <sub>5</sub> FeS <sub>4</sub>	63.3
Enargite	Cu <sub>3</sub> AsS <sub>4</sub>	48.4
Tetrahedrite	Cu <sub>4</sub> SbS <sub>4</sub>	46.7
Oxide ores:		
Cuprite	Cu <sub>2</sub> O	88.8
Tenorite	CuO	79.9
Malachite	CuCO <sub>3</sub> · Cu(OH) <sub>2</sub>	57.5
Azurite	3CuCO <sub>3</sub> · Cu(OH) <sub>2</sub>	55.3
Chalcanthite	CuSO <sub>4</sub> · 5H <sub>2</sub> O	25.5
Brochantite	CuSO <sub>4</sub> · 3Cu(OH) <sub>2</sub>	56.2

are either copper-nickel or copper-zinc-lead ores. The copper-nickel ores are the most abundant and occur as the sulfides. These ores produce large tonnages of copper and the majority of the world's supply of nickel and platinum as a by-product. Other deposits contain many complex ores. Copper frequently occurs in the ores of zinc and lead and may be produced as a by-product of operations for the recovery of these metals. Deposits of native copper as small grains in amygdaloid or conglomerate rock occur in the state of Michigan. Chalcopyrite is found in massive pyrite in the Riotinto deposits in the province of Huelva, Spain, and also in the state of Tennessee.

### COMMERCIAL PRODUCTION PROCESSES

The commercial production of copper is mainly by pyrometallurgical (smelting) methods or by hydrometallurgical (leaching) methods, usually followed by electrolytic refining or recovery. In general, the sulfide ores are treated pyrometallurgically, after flotation, and the oxide ores are treated hydrometallurgically. Most of the new copper produced by the latter 1950s was from sulfide ores. The sulfide minerals are usually found admixed with relatively large amounts of worthless rock or gangue. It is therefore economical to concentrate the valuable minerals into the smallest possible tonnage prior to smelting.

By the 1950s selective flotation was almost universally used on sulfide minerals for concentration, although gravity methods had been popular in the past. In selective flotation the finely ground ore mixed with water and selected reagents is subjected to violent agitation with air to produce a heavy froth. The reagents are so selected that great attraction exists between the surface of the valuable mineral particles and the air bubbles and only a small attraction between the gangue particles, which are readily wetted by the water, and the air. As a result the mineral particles cling to the bubbles of the froth and are carried to the surface while the gangue particles sink to the bottom of the container. It is necessary only to remove the froth from the container to separate roughly the minerals from the gangue material. Perfect separations are of course impossible, but with constant supervision, repeated treatment and exacting controls it is possible to concentrate 95% or more of the copper into 10% to 20% of the original weight, and to eliminate most of the gangue and much of the worthless sulfide.

The resulting concentrate containing the copper sulfides, some sulfides of other metals and a residue of gangue minerals if smelted in a reducing or neutral atmosphere with suitable fluxes will form two liquid layers. The upper layer is the slag which contains the gangue minerals and the fluxes, while the lower layer is a mixture of molten sulfides known as a matte (see below).

Some copper smelters continued to roast the concentrate before smelting, usually for the purpose of eliminating some of the sulfur from the concentrate by changing some of the sulfides into oxides and expelling the sulfur in the form of sulfur dioxide gas. The other purpose of roasting is to eliminate by volatilization as much as possible of the arsenic and antimony that may occur as impurities in the concentrate.

The partial elimination of sulfur from the concentrate will control the composition of the matte obtained upon smelting. When fusion takes place, all of the copper combines with sulfur to form

BY COURTESY OF KENNECOTT COPPER CORPORATION

ELECTRIC SHOVEL, USED IN STRIP MINING, WITH AN EIGHT-CUBIC YARD DIPPER CAPABLE OF LOADING 20 TONS EACH TIME THE BUCKET IS FILLED

$\text{Cu}_2\text{S}$ ; the remaining sulfur combines with iron to form  $\text{FeS}$ . Thus, if some sulfur has been eliminated by previous roasting, only a part of the iron can go into the matte as  $\text{FeS}$  and the remainder will be rejected to the slag. At one time all smelters roasted the concentrates in order to get upon smelting a matte high in copper and low in iron, about 45% copper being considered optimum. By the latter 1950s most new plants charged the concentrates directly to the smelting furnace with the thought that it is preferable to accept a lower grade of matte in order to avoid the cost and inconvenience of roasting.

**Roasting.**—Roasting is generally carried out in multiple-hearth furnaces. These furnaces consist of a refractory-lined vertical shell from 14 to 25 ft. in diameter with a central vertical shaft. The furnace is divided into a suitable number of horizontal hearths through which centre or outside drop holes are provided. The charge is fed to the top hearth, and is slowly raked across the hearth from the centre to the outside by a system of arms and rakes fastened to the central revolving shaft. The movement on each hearth alternates from centre to outside so that the material travels across each hearth before dropping to the hearth below. The material leaves the furnace from the bottom hearth. Suitable ducts connect the upper portion of the furnace with a flue system for the evacuation of the gases and to supply a draft to draw air into the furnace. Air is admitted to the furnace through doors on the various hearths.

Ores of high sulfur content will usually roast autogenously; that is, once the furnace has been brought to roasting temperature the heat liberated by the burning of the sulfur will maintain the temperature without the use of extraneous fuel. Ores with a low sulfur content must have fuel burners located on suitable hearths. The temperature of the roast is maintained below the temperature of coalescence of the charge.

The reactions in the roasting furnace are oxidizing. Sulfur is oxidized to the dioxide and eliminated as such. Metallic sulfides, primarily those of iron but also some copper, on losing sulfur are left in the solid charge as the oxides. The resulting material, known as calcine, is a fine mixture of the sulfides and oxides of iron and copper, gangue material and nonvolatile impurities. The total sulfur content has been reduced to that desired for the subsequent smelting operation.

**Matte Smelting.**—The object of the first step in smelting is to produce a molten artificial sulfide of copper and iron. This material is known as matte and should contain all the copper, the desired amount of iron, and must have a specific gravity sufficiently high to ensure a clean separation from the gangue material, other undesirable compounds and the balance of the iron. Metallic oxides in igneous fusion react as bases and will combine with acid anhydrides to form stable compounds of relatively low specific gravity. These compounds, known as slags, are usually formed by the use of silica,  $\text{SiO}_2$ , as the acid anhydride. The formation temperature and the fluidity of the slag is a function of its composition. The action of the slag on the furnace lining is a function of its acidity. It is necessary then to balance the composition of the slag to secure the desired results. This is done by the addition to the furnace of selected materials to give a slag of the desired composition and properties. These materials are known as fluxes, and the most common are limestone,  $\text{CaCO}_3$ , or silica,  $\text{SiO}_2$ .

Matte is generally smelted in reverberatory furnaces. These are large oblong furnaces from 20 to 30 ft. in width and from 90 to 130 ft. in length. They are usually constructed with heavy silica brick side walls reinforced with steel buckstays and tie rods, and with a low roof of the sprung-arch type if of silica brick or of the suspended-arch type if of magnesite brick. The furnace is equipped with from four to eight fuel burners at one end and flue connections at the other end. The charge is fed through the roof near the burner end and the molten material flows toward the flue end, where it collects in a large pool. The slag, being the lighter material, rises to the top, where it is drawn from the furnace through a hole in the wall. The slag is usually discarded. The matte collects in the bottom of the pool and is held until needed in the subsequent operation, when it is drawn out through a tap hole near the bottom of the pool. Large quantities of fuel are used in

these furnaces, and the temperature of the exhaust gases is high. Waste heat boilers are usually installed in the flue systems to recover a portion of this heat.

Matte may also be smelted in blast furnaces, but their use is restricted to a few locations. Although extensively used in the past, they are not easily adaptable to the smelting of the fine feed resulting from selective flotation. By the latter 1950s electric furnaces also were used for matte smelting.

**Matte Converting.**—Copper has a lower affinity for oxygen than has iron or sulfur. This, and the fact that the oxidation of iron and sulfur liberates large quantities of heat, is the basis of matte converting. Molten matte can be oxidized by introducing into it a stream of air. At the point where the air enters, iron, sulfur and copper will be oxidized. The copper oxide will immediately react with any iron sulfide still present to reform the sulfide of copper and form the oxide of iron. As air continues to flow through the molten mass, a time would arrive when all the iron would be present as the oxide, the copper as the sulfide, and the sulfur originally with the iron would have left the charge as sulfur dioxide. Since iron oxide will form a fusible slag with silica, it is necessary only to add to the molten mass sufficient silica to form the desired slag, and all the iron may be removed as an iron silicate slag while the heavy copper sulfide remains behind. The oxidation of the iron and its sulfur liberates sufficient heat to keep the material molten and melt the necessary silica and any other solid charge which it may be necessary to add. If air continues to enter the charge after the removal of the slag, the oxidation of the sulfur and the copper will continue and the copper oxide so formed will at once react with the copper sulfide remaining in the charge to form sulfur dioxide and metallic copper. These reactions liberate just sufficient heat to keep the charge molten. Ultimately a time will come when all sulfur has been oxidized, and metallic copper and a small amount of copper oxide will be present in the charge. Small amounts of minor impurities will also be present.

These reactions are carried out in the copper converter, usually of the Peirce-Smith type. These furnaces are a revolving refractory-lined horizontal drum about 13 ft. in diameter and about 30 ft. long. They are fitted with an opening at the top through which the furnace is charged and through which the gases escape when the furnace is in operation. Along one side is a large pipe which delivers compressed air to the furnace through a number of small pipes which enter the furnace through the side. These air ports are known as tuyères and are about 1½ in. in diameter and located from 12 to 18 in. apart along the entire length of the furnace. Air enters the tuyères at about 14-lb. pressure per square inch. The tuyères are so located that when the furnace is revolved to allow charging, they are above the level of the molten material in the furnace, and when the furnace returns to operating position, they are below the level of the molten charge. This introduces the air into the molten charge in a number of fine streams.

The matte is charged to the converting furnace directly from the reverberatory furnace and the blow begins at once. Silica as a solid flux is added as the temperature rises, and the slag is poured from the furnace as necessary. More matte is added as slag is removed, and ultimately the furnace is nearly full of molten copper sulfide. At this time slagging is complete and the final blow begins. Oxidation continues until all the sulfur has been removed and molten copper remains. If this metal is cast and solidified the surface will take on a rough blistered appearance caused by the liberation of dissolved gases as the metal cools. For this reason the material is known as blister copper. Blister copper can be cast and shipped to refining plants or it can be charged molten to refining furnaces adjacent to the converting plant. The latter is the more common practice.

The slag formed in the converting operation will carry an appreciable amount of copper. To avoid loss of this copper, the converter slag is returned to the reverberatory furnace, where much of the metal is converted to the sulfide and joins the matte, and the balance of the slag leaves with the reverberatory slag.

**Fire Refining.**—Blister copper, in addition to copper oxide, contains small quantities of other impurities. These impurities are best removed by fire refining. The furnaces used for this pur-

pose are either small reverberatory-type furnaces or revolving furnaces similar to the copper converter. They are equipped with fuel burners which melt the charge, if necessary, and maintain it in a molten condition throughout the refining operation. Air is forced through the molten material to ensure complete oxidation of all impurities, and then the oxides are allowed to rise to the surface of the quiet pool from which they are skimmed and returned to the converter. The oxidizing treatment is followed by a reducing treatment known as poling. This is done by forcing the ends of green logs into the pool of molten metal. The highly reducing gases resulting from the destructive distillation of the green logs reduce most of the copper oxide present in the metal. During this operation frequent samples are taken from the bath, cast and examined to determine the degree of deoxidation. When the proper stage has been reached, the sample has a distinctive metallic rose colour. This metal is called tough pitch, and may be readily cast into dense slabs.

Commercial tough-pitch copper is usable in this form. It will, however, contain any gold and silver recoverable from the original ore and traces of other impurities which are detrimental in many uses. The gold and silver often make their recovery economically attractive, and the removal of other impurities to produce a pure metal adaptable to all uses accounts for the final state of purification.

**Electrolytic Refining.**—When an impure copper anode and a copper cathode are immersed in a solution of copper sulfate and an electric current is imposed across the cell, copper ions from the solution will migrate to the cathode and be deposited as metallic copper, and copper from the anode will enter the solution. For each ion deposited on the cathode, an ion will enter the solution from the anode. Impurities in the anode will be liberated and will settle to the bottom of the cell as a slime. The net result will be the ultimate transfer of copper from the anode to the cathode, resulting in a deposit of pure copper and the formation of a cell slime which contains the gold, silver and other insoluble impurities. The rate of the transfer of the metal will be proportional to the quantity of electricity passing through the cell in unit time, and the total weight of copper deposited on the cathode will be proportional to the total quantity of electricity in accordance with Faraday's law.

This principle of purifying or refining is extensively used, and the molten copper from the fire-refining furnaces is usually cast into suitable shapes and sizes to be used as anodes in electrolytic refining cells. The size and weight of these anodes vary greatly in different plants, usually from 350 to 700 lb. in weight, 30 to 40 in. long and 24 to 36 in. wide.

Two general systems of electrolytic refining are in use, the multiple system and the series system. Economic factors dictate the system which will be employed. In the multiple system separate anodes and cathodes are used, the cathodes consisting of thin sheets of high-purity copper known as starting sheets. In an individual cell all of the anodes are connected in one parallel group and all of the cathodes in another. In the series system no starting sheets are used, the electrodes of impure copper being in series in a single cell and serving as both anode and cathode. This allows the impure copper to be corroded from the face of an electrode while pure copper is deposited on the back. The multiple system is the most widely used.

Starting sheets for use in the multiple system are prepared in special electrolytic cells known as stripping tanks. In these tanks regular anodes are used, but the cathodes are smooth rolled copper sheets with lightly oiled surfaces. The pure copper deposit is stripped from the sheets when of the proper thickness, straightened and used as cathodes in the regular cells. The current density, the intensity of the current per unit area, influences the physical characteristics of the deposit. In general, the lower the current density, the finer the grain and the greater the strength of the deposit. Stripper tanks operate on relatively low current density, usually from 14 to 18 amp. per square foot. Starting sheets are stripped when about  $\frac{1}{8}$  in. in thickness, and before insertion in the cells are fitted with copper strips at the top through which the bar serving as the electrical connection is passed.

The cells in the multiple system are connected in series. The number of cells in a single series is determined by the voltage drop across each individual cell and the total voltage at which the direct current is supplied to the system. The current passing through an individual cell amounts to several thousand amperes, and heavy conductors are required to carry it without overheating. These conductors, which lie along each side of the cell, are known as bus bars and are arranged so that the anodes contact the positive bus bar and the cathodes contact the negative bus bar. They are made of cast copper and are rectangular in cross section.

In operating the cells, the anodes are placed in position by an overhead crane; the starting sheets are placed by hand. The electrolyte is continually circulated through the system to prevent segregation of salts and to allow control of the composition of the solution and the removal of soluble impurities. Current density is usually between 18 and 24 amp. per square foot and is maintained until the cathode is about one-half inch in thickness. At this time the cathode is removed and a new starting sheet inserted. About four starting sheets are usually used for each anode and from 10 to 15 days are required for each cathode. When the anode has completely corroded, the remaining contact lugs and other scrap are remelted and recast into new anodes. The cell slimes are removed for treatment and the recovery of valuable materials.

The series system of refining usually employs electrodes smaller in size than those used for the multiple system, usually weighing about 100 lb. each. These electrodes are carefully cast and are sometimes rolled in order to make them as smooth as possible. The cells are larger than those used in the multiple system, and only the first and last of the electrodes are connected electrically. The current entering the tank at one end through the copper electrode passes through the electrolyte from electrode to electrode, corroding copper from the face of one and depositing it on the back of the next. This operation is allowed to proceed until nearly all the impure copper has been corroded, at which time the electrodes are withdrawn, and the small amount of impure copper remaining is scraped from the deposit of pure copper.

Electrolytic refineries are usually large plants consisting of several hundred cells, each using 25-35 anodes or electrodes. Large purification plants are often needed to maintain the proper analysis and specific gravity of the electrolyte.

After electrolytic refining, the cathodes are melted in furnaces similar to those used for fire refining or in electric furnaces, and are cast into the desired shapes for market. The most common forms are wire bars, cakes and ingots. This material is known as electrolytic copper and is suitable for practically all commercial uses. Special treatments can be used during the melting process for the production of oxygen-free copper. This involves the use of special apparatus to allow the melting and casting of the cathodes without any oxygen entering the copper.

**Hydrometallurgy.**—This involves the treatment of the ore with a suitable solvent which will take the copper into solution and leave all or a major part of the undesirable material unaltered. The copper must then be recovered in a relatively pure form from the solution.

The oxide ores of copper lend themselves to the foregoing treatment. Sulfuric acid readily dissolves the oxides of copper and has little effect on the common gangue materials, excepting some of the salts of iron. Many of the oxide ores are not amenable to concentration and it is necessary to treat or leach the ore as mined. The material is agitated or soaked with the leach solution. Elaborate systems of washing and filtering or settling are necessary to recover the optimum amount of copper.

The leach solutions are usually subjected to some type of purification for the removal of the soluble iron and other objectionable impurities. This often involves neutralization and oxidation followed by the removal of the precipitated ferric salts.

Direct leaching of sulfide concentrates can be achieved by the use of elevated temperatures and high pressures such as are attained in autoclaves. These procedures are usually limited because of cost to mixed nickel-cobalt-copper concentrates with high value; both acid and basic solutions are used.

Two systems of recovering the copper from the leach solutions are in general use: precipitation and electrolytic recovery.

**Precipitation.**—Since copper lies below iron in the electromotive series of the elements, iron will displace copper from the solutions of its salts. Metallic iron in any form if added to a solution of copper sulfate will enter the solution and displace metallic copper. This system of copper recovery is used where relatively small tonnages of copper are to be recovered and the smelting of the recovered copper is feasible. It is used extensively for the recovery of copper from mine waters.

The operation involves leading the solutions to be treated through suitable tanks or agitators in the presence of metallic iron. Scrap iron or detinned scrap from the manufacture of tin cans is most commonly used. Traps to collect precipitated copper are installed in the system. The spent solutions are usually discarded. The copper so produced is a fine brown powder and contains an appreciable amount of entrained iron and other impurities. Relatively high recoveries are made and the material lends itself readily to smelting with normal smelter feed.

In plants using pressure leaching techniques it is also quite feasible to precipitate copper from solution in the form of a granular powder by introducing hydrogen gas under high pressures.

**Electrolytic Recovery.**—When an insoluble anode and a copper cathode are immersed in a solution of copper sulfate and an electric current is imposed across the cell, copper will deposit on the cathode in the same manner as when a soluble copper anode is used. At the anode, however, a different reaction takes place. The hydroxyl ion ( $\text{OH}^-$ ) of the water is oxidized with the liberation of oxygen leaving a surplus of hydrogen ions ( $\text{H}^+$ ). The net cell reaction is the sum of the anodic and cathodic reactions and is the decomposition of copper sulfate and water and the formation of metallic copper, sulfuric acid and oxygen. This reaction is endothermic, absorbing heat. This heat, or its equivalent, is supplied by electrical energy theoretically amounting to 1.195 v. and is called the decomposition voltage of copper sulfate. It is necessary then to supply current to each cell at this voltage plus the necessary voltage to overcome the resistance of the electrolyte, contact losses and overvoltages. In practice this amounts to about two volts. The process requires large quantities of electrical energy.

Cathodes for these electrolytic cells are starting sheets prepared in a similar manner to those used in the multiple system of refining. Anodes vary greatly at different plants, the alloys of antimony and lead and the copper silicates being the most common. The electrolyte is continually circulated between the cells and the leaching plant in order to utilize the regenerated sulfuric acid, to allow purification of the solution and to avoid the electrolysis of solutions too depleted in copper sulfate. The cathode copper produced is of high purity and is melted and cast in the same manner as cathode copper from electrolytic refining.

Hydrometallurgical and electrolytic recovery plants are widespread over the world, the largest individual plants being located in Chile, Republic of the Congo and the state of Arizona. Most plants must adopt special methods and techniques to meet their individual problems and often combine in one plant many or all of the various methods for the winning of copper from its ores. (See also HYDROMETALLURGY.)

**Secondary Copper.**—As a result of its durability, large tonnages of scrap or reclaimed copper become available each year from obsolete or discarded machinery and equipment. This material is readily converted into usable metal by its addition to smelter feed, or by remelting and refining at secondary plants. See ALLOYS; BRASS; BRONZE.

(J. P. Sp.; A. W. S.)

## MANUFACTURE, USES, ALLOYS AND PRODUCTION

**Manufacturing Uses.**—The major portion of the world's production of copper is utilized by the electrical industries; of the remainder the greater part is combined with other metals to form alloys. This leaves a comparatively small portion of the total production to be absorbed for general purposes.

The division of copper, including copper contained in alloys, among the principal industries using it is as follows in the U.S.,

the figures in parentheses indicating the approximate percentage of the total consumption used for that purpose:

Electrical manufactures, including generators, motors, electric locomotives, switchboards, light bulbs, etc. (22%); telephones and telegraphs, light and power lines (13%); other rod and wire (9%); automobiles, not including starting, generator and ignition equipment (10%); buildings, excluding electrical work (10%); manufactures for export (11%); other uses (25%). Uses of copper included in the last item, stated approximately in the order of tonnage consumed, are ammunition, radio and television, air conditioning, refrigerators, railroads, shipbuilding, screening, copper-bearing steels, radiators and heating, clocks and watches and numerous others.

**Standard Electrolytic Copper.**—Typical samples of electrolytic copper contain from 99.92% to 99.96% copper. About 0.03% oxygen is purposely left in the copper, since this amount will slightly improve the density and the conductivity. Copper in this condition is known as tough pitch. Its conductivity is 100% to 102% of the International Annealed Copper Standard (I.A.C.S.). On this standard, 100% denotes a resistance of 0.15328 ohm for a length of 1 m. weighing 1 g., at 20° C.; the I.A.C.S. was universally adopted for industrial purposes.

A relatively small but increasing amount of copper is manufactured free from oxygen, because this type has sufficiently greater ductility to make it better for severe working operations, and because it can be annealed in reducing atmosphere without developing porosity and brittleness. Removal of oxygen may be accomplished with a deoxidizing agent, such as phosphorus contained in a phosphor-copper alloy; this method leaves a little of the deoxidizing element in the copper, which in the commonest product lowers its conductivity enough to make it unfit for electrical conductors.

Other methods were developed of making copper free of oxygen with approximately the same conductivity as tough-pitch copper.

**Copper Wire, Sheet and Strip.**—For making copper wire, electrolytic copper is first cast into wire bars, which are made in several standard sizes varying in weight from 135 to 500 lb. The wire bars are then reheated to 700° to 850° C. and are rolled without further reheating to rods approximately  $\frac{3}{8}$  in. in diameter. The rod is drawn cold into wire, through dies of successively smaller diameters until the desired size is reached. The dies are usually of tungsten carbide; for the finer wires diamond dies are often used.

Great advances have been made in the machinery used for wire drawing and multiple-die machines are in common use. In order to minimize oxidation and scaling, special types of furnaces are employed for annealing the coils between the drawing operations. A typical example is a gas-fired furnace chamber, the ends of which pass beneath water seals.

Much of the copper wire is marketed in the form of bare coils in the half-hard condition, but there is also a considerable tonnage which is subsequently covered with paper, fabric, rubber, plastic or other insulating material for use in the form of covered conductors. Much of the wire is also supplied stranded, and all these operations are carried out on special machines which are largely automatic in operation.

Copper cables, in many cases, have to undergo a special process to render them as resistant as possible to moisture, and at a later stage they may receive an outer protective covering, lead being the final protection in many instances. Lead covering is extruded onto the outside of the cable by means of a special extrusion apparatus. For immersion under water an additional protection sometimes has to be given in the form of hemp or metal armoring. Various designs of multiple-cored and other special types of cable are manufactured and supplied for various purposes. The electrical industries also use large quantities of bare copper strip for incorporation in electrical machinery. In the narrow widths and thicker gauges this form of the metal is produced mainly from wire bars which are rolled in a mill of a type similar to that used for the production of wire. In addition, copper strip of greater width and much thinner gauge is

produced in long lengths, and is usually supplied in the form of coils.

The term copper strip as distinct from copper sheet is usually assumed to apply to material less than 24 in. wide which is supplied in long lengths. The majority of the strip used is less than 12 in. wide. In the preliminary stages of manufacture, the copper castings are rolled hot, but in the later stages of manufacture all the rolling is carried out cold, the material being coiled on coiling drums on each side of the rolling mills. Material produced by this method is of very even gauge and possesses an exceptionally good surface finish. The coils can be handled easily and are in general use for the manufacture of stampings, both in the electrical and other industries. Copper strip is supplied in various degrees of hardness according to the rolling it has received subsequent to the last annealing. The usual grades of hardness or temper are termed soft, quarter-hard, half-hard, three-quarters-hard and hard. These various tempers are selected according to the amount of subsequent mechanical deformation to which they will be subjected. Copper sheets are produced by somewhat similar methods of manufacture; in the United States especially, the majority of copper sheets are made from electrolytic copper, but in Europe fire-refined arsenical copper is used frequently in the manufacture of sheets and plates.

U.S. and British practice is to use relatively small cast cakes of from 100 to 400 lb., which are rolled out and cut to size. Both hot-rolling and cold-rolling are practised, depending on the surface of the sheet required, but U.S. practice tended more and more to use cold-rolling for the final stages in sheet production, irrespective of the surface finish required. In Europe several finishes are marketed: the hot-rolled and descaled sheet is known as ordinary quality and has a distinct colour which is greatly valued in certain parts of the world. The red coloration is caused by a thin film of cuprous oxide, which is easily removed by immersion in dilute acid.

**Cold-Rolling.**—Cold-rolling is an operation carried out subsequent to hot-rolling, and gives a sheet with an exceptionally smooth, bright finish, suitable for working up into highly polished articles. Cold-rolled sheets are manufactured in a variety of tempers similar to those already quoted for strip copper. In Europe methods were developed to allow the use of large castings up to several tons in weight for sheet manufacture, and progress was also made in the manufacture by strip-rolling methods of much greater widths than had previously been attempted. In this method of manufacture the greater part of the rolling is a modified form of cold-rolling, and the resultant sheets show a surface finish which is smoother than that obtained by the ordinary methods of hot-rolling. In the thicker gauges, copper sheets find application in many industries, and are manufactured into pans and vessels of all kinds.

The high heat conductivity of copper is of great value for such purposes, in addition to which the malleable nature of the metal allows it to be worked into very intricate shapes. Where the metal is subjected to furnace gases and relatively high temperatures, it is generally considered that pure copper is not as satisfactory as arsenical copper containing approximately .5% arsenic. This applies also to the use of copper in locomotive fireboxes.

**Extrusion.**—Extrusion is commonly used as a method of manufacture of copper bus bars and similar elongated shapes of large or small cross section; also rods, either round, hexagonal or square, and some complex structural shapes of copper and copper alloys. In this process a billet is heated and then forced ahead, by the application of pressure, through a die, thus obtaining in one operation a cross section determined by the size and shape of the die.

**Alloys of Copper.**—In variety of uses these surpass all other nonferrous alloys and comprise mixtures of copper with zinc, tin, nickel, aluminum, lead, manganese and other elements. In some instances they consist simply of binary alloys formed by the addition of one other metal to copper, but in many cases two or more metals may be added in order to impart certain special properties. The most important series of alloys in which copper

forms the chief constituent are the brasses (copper-zinc), bronzes (copper-tin) and nickel silvers (copper-zinc-nickel). For these alloys see BRASS and BRONZE.

In addition to these better known alloys, there are many others which found application in industry as their properties became more widely recognized. Those of copper and nickel are important examples; their manufacture increased greatly during the 20th century. Because copper and nickel are completely miscible in the solid state, forming a complete series of solid solutions, the useful range of alloys is not confined within any definite limits of composition, although certain compositions came into general use. Additions of 2%-45% nickel to copper provide a series of alloys which are considerably stronger and more resistant to oxidation at high temperatures than is copper. Of these "cupronickels," that containing 30% nickel is the most important; it is widely used for condenser tubes. The U.S. five-cent coin, popularly called a "nickel," is 75% copper, 25% nickel.

The alloy formed of 20% nickel with the remainder copper is one of the most ductile of commercial alloys, and may be subjected to the most severe cold-working without the need of any intermediate annealing. It is also readily forged and rolled at a temperature above 800° C. These properties make it a very suitable alloy for drop forgings and cold stamping and pressing, and it found a variety of uses in automobile construction for exposed fittings, as it takes a high polish and is resistant to atmospheric tarnishing. Other uses include bullet sheathing, for which purpose it was used by many nations including Great Britain and France. In the form of tubes its use was rapidly extended for steam condensers, although the alloys containing 25% nickel and 30% nickel were stated by some authorities to give better results as condenser tubing than the softer and less resistant alloys of lower nickel content. Another alloy in this series containing either 45% or 40% nickel became widely known under the name constantan. It has a high electrical resistance which remains almost constant over an appreciable range of temperature.

Monel metal is a so-called natural alloy prepared by the reduction of a copper-nickel ore and containing 65%-70% nickel. In addition to copper and nickel it contains iron and manganese in small amounts, together with other impurities which influence its properties to some extent. It has been widely used for various engineering and ornamental purposes, and possesses exceptionally high strength at both normal and elevated temperatures. Alloys of similar nickel content are also manufactured by melting nickel and copper together.

Copper also forms an important series of alloys with aluminum which are classed under the general term aluminum bronzes. The properties of these alloys were the subject of numerous scientific investigations which showed that the useful alloys rich in copper contain up to 11% aluminum. They may be classified into two main groups: those containing up to 7.5% aluminum are extremely ductile, while those containing 8%-11% possess high tensile strength in the cast state. The ductile alloys containing less than 7.5% are especially useful for deep stamping, spinning and severe cold-working of all kinds, and found application as a substitute for brass, compared with which they possess greater strength and resistance to atmospheric corrosion. Bronze coinage such as that used in France contains 8.25% aluminum together with a little manganese, and this mixture approaches very nearly the upper limit for satisfactory cold-working. The alloys with 8%-11% aluminum usually contain in addition 1%-3% iron and are in general use for die castings, for which their high tensile strength and clean casting properties are a great advantage. They are resistant to corrosion by mineral acids and also resist oxidation at relatively high temperatures.

Copper alloys are often classified as those used for making castings and those used for wrought materials. Castings usually require machining, but the toughness of copper and most of its alloys make them difficult to machine. Machinability can be greatly improved by addition of lead, which is often a component of the casting alloys. Leaded brass, bronze and other alloys which may be wrought if the lead content is low, often contain from .5% to 10% lead.

Silicon bronze usually contains about 96% copper. The remainder may be silicon alone, but more often a little manganese, tin, iron or zinc is also added. These alloys were developed originally for the chemical industry because of their exceptional resistance to corrosion in many liquids. Their application later extended far beyond this field, chiefly because of their good casting qualities, satisfactory strength and hardness and ease of welding in addition to corrosion resistance.

Unlike many kinds of steel, most copper alloys are not susceptible to improvements of hardness and strength by processes of heat treatment. One useful exception is the heat-treatable alloy beryllium copper. This consists of copper with addition of about 2% of beryllium, with or without a smaller addition of nickel or cobalt.

When beryllium copper is heated to about 800° C., quenched in cold water and then reheated to 275° C., it develops a tensile strength up to 200,000 lb. per square inch, comparable with some of the stronger varieties of steel.

Manganese bronze is made in several varieties, exhibiting a range of compositions and properties. One type is in reality a brass to which a very little manganese has been added as a deoxidizer, less than .5% manganese remaining in the alloy. Another kind contains 2%–5% manganese together with 2%–4% iron and 3%–7.5% aluminum. It has exceptionally high strength, and is called high-tensile manganese bronze or manganese-aluminum bronze. Phosphor bronze is a true copper-tin bronze to which a little phosphorus is added as a deoxidizer and strengthener.

There are numerous other variations of the different copper alloys, and their development is an example of the progress of metallurgical science in providing materials to meet modern industrial requirements.

**Output.**—Ever since there has been any knowledge of the world production of metals, copper has exceeded all other metals except iron. During and after World War II, however, the production of aluminum grew more rapidly than that of copper, and by the mid-1950s aluminum had closely approached copper in world tonnage. A principal reason for this was the reversal in price position whereby copper, formerly cheaper than aluminum, became more costly. Though the output of aluminum increased more rapidly, copper also grew in production and use.

Just before World War I the annual production of copper in the world was about 1,000,000 metric tons. In 1939 it reached more than 2,000,000 tons, and in 1943, under the stimulus of demand for war purposes, it rose to almost 3,000,000 tons. It declined after World War II and then began rising to a new peak, reaching about 4,000,000 metric tons by 1960.

Before World War I considerably more than half of the world's copper came from the United States, but this proportion declined to one-third by mid-century. In order to meet the demand for copper, it became necessary to use ores of lower and lower grade, which accounted in large part for the increase in price.

See BRASS; BRONZE; ALLOYS; ZINC; ALUMINUM; etc.

(AL. BU.)

## CHEMICAL AND PHYSICAL PROPERTIES

Copper lies between nickel and zinc and is in subgroup Ib (copper, silver, gold) in the periodic classification of the elements. It is the ninth of the ten transition elements occurring between calcium and gallium and is the first element in which the atom has a complete third shell of 18 electrons. The electron arrangement indicates that the natural valence of copper is 1 and that the properties of its compounds in which the oxidation state is 1+ (cuprous) should resemble those of silver and to a lesser degree those of gold. This is true, since the cuprous salts resemble to a great degree those of silver, and some of the naturally occurring compounds of the two metals resemble each other and frequently occur together.

Copper lies below hydrogen in the electromotive series of the elements and consequently does not replace hydrogen from solutions. It lies below iron, zinc and lead, and these metals will displace copper from solutions of its salts. Platinum, gold, silver

TABLE II.—Properties of Copper

Physical constants:	
Atomic number	29
Atomic weight	63.54
Atomic volume	7.10

Valence	1 or 2
Periodic classification	Group 1, series 5, period 4

and mercury lie below copper and are displaced from solutions of their salts by copper.

Although copper is not soluble in acids with the evolution of hydrogen, it is readily soluble in oxidizing acids or in acids in the presence of other oxidizing agents; for example, nitric acid, hot concentrated sulfuric acid, or sulfuric acid and ferric sulfate. Copper is also soluble in ammonia and ammonium salts in the presence of air and in sodium and potassium cyanide.

Copper resists the action of the atmosphere and sea water to a high degree. Exposure to the atmosphere for long periods results in the formation of a thin coating of green basic copper carbonate known as patina. This beautiful green colour characterizes copper objects such as roofs and statuary, especially in the vicinity of the sea.

**Physical Properties.**—Many of the common gases such as oxygen, nitrogen, carbon dioxide and sulfur dioxide are soluble in molten copper. The degree of this solubility has a profound bearing on the mechanical properties of the solidified metal but presents a problem difficult to investigate.

Copper is one of the most ductile of the metals, and although not especially strong or hard, both strength and hardness are appreciably increased by cold-working. Soft commercial copper will vary in tensile strength from 30,000 to 36,000 lb. per square inch. This may be increased by severe cold-working to a maximum of about 70,000 lb. per square inch. Cold-working reduces ductility but annealing after cold-working will restore it.

Copper has no allotropic forms and therefore has no critical temperature at which changes take place in the crystalline pattern. The softening effect of annealing is simply the formation of a new crop of equiaxed crystals in place of the elongated crystals formed by cold-working. The lowest recrystallization temperatures lie between 200° and 400° C. The metal may be hot-rolled or formed at any temperature above the recrystallization temperature and below the melting point without work hardening.

Copper may be welded, brazed or soldered either with the electric arc or the oxyacetylene torch. The metal, however, cannot be cut with the oxygen lance in the manner of steel.

## CHEMICAL COMPOUNDS

Copper forms two series of compounds in which its oxidation state is 1+ (cuprous) and 2+ (cupric); several unstable compounds of the 3+ state are also known. Since the cuprous ion is unstable in aqueous solution, its salts readily decompose to form the metal and cupric salts:

The cuprous state is therefore maintained only in insoluble salts as CuI or in complex ions as  $\text{CuCl}_2^-$  and  $\text{Cu}(\text{CN})_3^-$ . The cupric ion in dilute water solution is hydrated  $\text{Cu}(\text{H}_2\text{O})_4^{2+}$  and is blue in colour. With ammonia it forms the deep blue complex  $\text{Cu}(\text{NH}_3)_4^{2+}$ .

**Oxides.**—Copper forms two oxides in accordance with its two valences: cuprous oxide,  $\text{Cu}_2\text{O}$ , and cupric oxide,  $\text{CuO}$ . Cuprous oxide, a red crystalline material, can be produced by electrolytic or furnace methods. It is reduced readily by hydrogen, carbon monoxide, charcoal or iron to metallic copper. It imparts a red

colour to glass and is used for antifouling paints. It is soluble in mineral acids to form colourless cuprous salts, most of which rapidly oxidize to the cupric state. Cupric oxide, a black powder, can be prepared by the ignition of suitable salts such as the carbonate, hydroxide or the nitrate of copper, or by heating of cuprous oxide. This compound will oxidize carbon compounds and finds a wide laboratory and commercial use for this purpose. Since it imparts a green colour to glass, it is used extensively for that purpose. It is soluble in mineral acids and forms with them blue or green solutions.

**Halides.**—Cuprous chloride,  $\text{CuCl}$ , can be prepared by treating metallic copper and cuprous oxide with hydrochloric acid, or by treating metallic copper and cupric chloride with hydrochloric acid. The hydrochloric acid solution of cuprous chloride readily absorbs carbon monoxide and acetylene and is used for this purpose in gas analysis. Cupric chloride,  $\text{CuCl}_2$ , can be prepared by dissolving cupric oxide in hydrochloric acid. This material finds some use as the base salt for the manufacture of pigments. Cuprous iodide,  $\text{CuI}$ , is prepared by the direct combination of copper and iodine. Cupric iodide,  $\text{CuI}_2$ , exists only in combination with ammonium salts or in complex organic compounds.

**Sulfides and Sulfates.**—Cuprous sulfide,  $\text{Cu}_2\text{S}$ , occurs in nature as the mineral chalcocite. The compound may be prepared by the direct combination of copper and sulfur at high temperatures. Cupric sulfide,  $\text{CuS}$ , occurs in nature as the mineral covellite and can be prepared in the laboratory by treating the solution of a copper salt with hydrogen sulfide. Both compounds are insoluble in mineral acids.

Cupric sulfate,  $\text{CuSO}_4$ , commonly known as blue vitriol, is the most important salt of copper. It usually crystallizes as  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  and has a bright blue colour. It is prepared by the treatment of copper oxides with sulfuric acid. While readily soluble in water it is insoluble in alcohol. The anhydrous salt is hygroscopic and is useful as a desiccating agent. Copper is readily displaced from aqueous solutions of the salt by metallic iron. Copper sulfate is the basic salt in the electrolytic refining of copper and it also finds a wide use in the preparation of pigments.

**Carbonates.**—Basic copper carbonates are formed when an alkaline carbonate is added to the solution of a copper salt. These compounds, which have a bright blue or green colour and are used in the preparation of pigments, occur in nature as the minerals azurite and malachite.

**Miscellaneous Compounds.**—Copper forms a series of salts with arsenic; all are bright green in colour and poisonous. Wide use has been made of these compounds in insecticides. Cupric nitrate,  $\text{Cu}(\text{NO}_3)_2$ , can be prepared by dissolving metallic copper in nitric acid. The hydrated crystals are deep blue in colour. Copper silicates occur in nature and impart a blue colour to many minerals.

**Detection.**—Solutions of copper salts take a characteristic deep blue colour when treated with an excess of ammonia. They impart a bright green colour to the flame of a Bunsen burner, and in dilute solutions produce a brown colour when treated with potassium ferrocyanide. The presence of minute quantities of the metal is readily detected with the spectrograph. For the quantitative estimation the electrolytic method and the potassium iodide method are widely used.

**Medical Uses.**—All salts of copper are poisonous and readily attack the mucous membrane even in low concentrations. They have limited uses, mainly as superficial antiseptics.

**COPPERAS** (Fr. *couperose*; Lat. *cupri rosa*, "the flower of copper"), a term formerly synonymous with vitriol and applied to the sulfates of copper, iron (ferrous) and zinc as blue, green and white copperas respectively. It is now applied exclusively to ferrous sulfate,  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ , a light green solid which has an

astringent, inky and somewhat sweetish taste and which is used in medicine, in dyeing and tanning, and in the manufacture of ink. See IRON: Compounds of Iron.

(J. B. Ps.)

**COPPERHEAD** (*Aghistrodon contortrix*), a venomous snake of the pit viper family (Crotalidae). It occurs in the eastern and

BY COURTESY OF SAN DIEGO ZOO

NORTHERN COPPERHEAD (AGHISTRODON CONTORTRIX MOKESON)

southern United States from Connecticut west to southeastern Nebraska, and south to northern Florida and western Texas. Four regional races (or subspecies) having different colour patterns are recognized. It is a small snake; although occasionally exceeding 4 ft., most adults are less than 3 ft. long.

Like its relative the water moccasin (see MOCCASIN), the copperhead (sometimes called the highland moccasin) bears living young, often four to eight at a birth. Mice comprise its preferred diet, but it eats other small mammals and lizards, frogs and insects. It favours rocky or woody habitats. In winter copperheads congregate for hibernation deep in ground fissures or rock crevices, often joined there by other snakes, including rattlesnakes.

In most areas copperheads are brightly coloured, with reddish head and body marked by brownish crossbands that are narrower along the back than along the sides. While usually mild-mannered, copperheads bite quickly if injured or frightened. Although rarely fatal, the bite should receive immediate medical attention, especially if the victim is a child. In Australia the name copperhead is applied to a quite different and far more dangerous snake, *Denisonia superba*, a species allied to the cobras and kraits.

(L. M. Kr.)

**COPPERHEAD**, a U.S. political epithet applied during the Civil War to those in the North who, deeming it impossible to conquer the Confederacy, were in favour of peace and therefore opposed the war policy of the president and of congress. The term "Copperhead" as one of opprobrium existed before the Civil War, but its first recorded use in the sense here described is believed to be in the *New York Tribune* of July 20, 1861. The name was adopted because of the alleged resemblance of the "peace democrats" to the venomous copperhead snake which does not rattle and strikes from concealment without warning, as: "A rattlesnake rattles, a viper hisses, an adder spits, a black snake whistles, a water-snake blows but a copperhead just sneaks!" Thus the antiwar Democrats were also called "sneak Democrats" and in the midwest, early in 1863, the terms "Copperhead" and "Democrat" had become virtually synonymous. Though applied opprobriously in this way, the term was willingly assumed by those upon whom it was bestowed, and some advocates of the peace policy, to emphasize it, wore Copperhead badges; these were generally made of one-cent copper pieces which had been cut away so that only the copper head remained, with Liberty written across the forehead. It is believed, however, that the badges did not appear until about six months after the term itself came into use.

The bases for antiwar sentiment were manifold, but differed in character and intensity with the region. In the midwest, there were factors such as an economic-based envy of industrial New England which was seen as fostering the war at the expense of the midwest; a continuing loyalty to the south, from which large segments of the midwest population had lately emigrated; a fear of growing centralization of government; and doubts about the possibly harmful consequences to themselves if slavery were abolished. In New England, it was largely a fear among merchants and manufacturers of losing a profitable commerce with the south should secession become a reality. In the middle eastern states, particularly New York and parts of New Jersey, there was the incentive among Democrats to make political capital out of the inevitable hardships of the war. And everywhere, of course, there were those who opposed civil strife under any circumstances.

In its organized aspect, the Copperhead movement was one of secrecy, quasi-military discipline, the taking of oaths, grandilo-

quent ritual, and, in its extremist form, terrorism and an arrogation of the law to private hands. It began in the middle west where it also remained strongest, but in the third year of the war it had spread to the east. To a lesser extent it also spread to the west where it did not, however, exercise any serious influence on the outcome of the war.

For the last two years of the war, branches of the secret anti-war society known as the Knights of the Golden Circle were on the whole localized. Originally, they sprang up mainly as agencies of mutual protection against arbitrary arrests, and shared, in addition, a common sympathy with the southern cause. They were and remained strongest in Ohio, Indiana and Illinois. In 1865 they merged into the Order of American Knights and became more actively defeatist in character and aim. They opposed conscription, gave aid to deserters, hindered shipments of men and supplies, and terrorized Union sympathizers. A year later the name of the order was changed to Sons of Liberty, the name of the secret associations in the American colonies during the opposition to the British Stamp act of 1765.

Leaders of the Copperhead movement included Clement L. Vallandigham (q.v.), their chief spokesman; Alexander Long of Cincinnati, O.; and Fernando Wood in New York. There was no formal dissolution of these societies after the war, but the Democratic party continued to suffer for some time from the aftermath of its association with the Copperheads. Almost a century later, and shortly before World War II, Pres. Franklin D. Roosevelt revived the epithet by applying it to the noninterventionist stand taken by Charles A. Lindbergh in 1941; as a result of the president's comment, Lindbergh resigned his colonelcy in the U.S. army air corps reserve.

**COPPERMINE RIVER**, in Mackenzie district, Northwest Territories, Can., rises in a small lake north of Great Slave lake. Flowing south through Lac de Gras and then northwestward, it joins a large number of irregular lakes to form Point lake. After flowing in rolling hill country, it breaks through the Coppermine and September mountains about 50 mi. from its shallow mouth on Coronation gulf, near which the settlement of Coppermine is located. The river is 323 mi. long and descends about 1,600 ft. Trees occur to within a few miles of the sea. Named by Samuel Hearne in 1771 who reached the mouth overland from Churchill while searching for copper, it was first traversed by Sir John Franklin in 1830. The lower 160 mi. is part of a formerly well-traveled route from Great Bear lake to the Arctic ocean. The largest lake drained by the Coppermine river is Takiyuak lake with an area of 410 sq. mi. (An. Kr.)

**COPRA**. Dried sections of the oil-bearing kernel of the fruit (nut) of the coconut palm (*Cocos nucifera*) are known in world commerce as copra. The less common drying of the intact whole nut kernel produces both edible oil and whole copra. Shredding of the fresh meat removed by thorough drying results in a food item, dehydrated coconut, in which the moisture content is somewhat lower and the oil content higher than that of copra. Copra, as known in trade, is a common food directly as human food, but is processed to extract the coconut oil of commerce, leaving a coconut cake, also called copra cake, poonac and *buangkil*, mostly utilized for livestock feed.

**History**. The coconut tree in its several varieties has a long history as a "tree of life," a regular supplier of food and other necessities of life. Because fresh coconut supplies were generally available throughout almost most of the year for the indigenous populations of the tropics, there was apparently little occasion to preserve it through long and overcast transport until northern Europe faced with a shortage of food fats in the 15th cen. began to experiment with copra as an economic source of cooking and table fats. As recently as 1875, though, this widely used in western Europe, coconut oil was practically unknown in the U.S. In the second half of the 19th century, world production of copra and coconut oil in oil equivalent was in the range of 2,200,000 to 2,400,000 short tons, about 1% of total world production of all fats and oils. Of that amount 1,300,000 to 1,500,000 tons per year

entered world trade, with western European countries and the United States the major importers.

**Production**.—Nuts gathered from naturally growing palms continue as the principal source of copra, though commercial coconut estates and smallholders' plantations provide significant quantities. The principal producing areas lie within 22° of the equator and below 900 m. altitude; temperatures must not fall below 20° C. (68° F.) and rainfall should exceed four feet per year. Cultivation of the coconut for copra is localized principally in the Philippines, India, Ceylon, Indonesia, Malaya and the Pacific islands. Under the most favorable practices, trees are spaced at 25-ft. intervals, with an expected harvest of 75 or more nuts per tree per year, or about 4,500 or more nuts per acre. Production begins in five to seven years after planting.

Nuts ripen throughout the year after they are about one year of age; they may be gathered as they fall, regardless of weather, in which case they must be processed promptly to obtain quality copra. The nuts also may be picked from the trees, in which case the greener nuts are seasoned for as much as four weeks in shallow piles. Eventually the nuts are husked by bringing them forcibly against a sharp point. This is in most areas hand work, though mechanical huskers are known. The shell is then cracked, normally into two halves, with a chopping knife, exposing the meat, which is about 28% by weight of the total nut and in its raw state is about 50% water and 30% to 40% oil. It requires about 10 nuts to provide meat for 10 lbs. of copra.

The earliest method of drying was to expose the kernels to the air and sun, a practice which is still extensively followed and gives a good quality white copra (sun-dried copra). A more primitive process, adopted particularly in districts where the humidity of the air is excessive, is drying by fire (kiln drying). The kilns consist essentially of a fire pit overlaid with a grid on which the copra is placed. The drying copra is sheltered from the rain by a roof. Such kilns are used generally in the Philippines, which supply 50% of the world copra exports. Broken coconut shells, wood and to some extent coconut husks are used as fuel. The copra is deliberately smoked in order to sterilize it, partially dried product and so modify the extent of self-heating and decomposition during subsequent natural drying in storage in the warehouse of the copra buyer. The copra does not remain in the kiln for more than two days. During this period the fire in the fire pit is kept going spasmodically.

Copra of better and more uniform quality is produced by another method—hot-air drying—first introduced in India and Samoa. The copra is drawn slowly through a heated tunnel, meeting a countercurrent of hot air. The method yields a fine, white copra of higher value than the sun-dried article. Well-dried copra as sold in world commerce contains 4% to 5% moisture. The proportion of oil in such copra ranges from 63% to 70%.

**Processing Copra**.—Coconut oil is obtained from copra by pressing in mechanical screw presses. In some areas hydraulic and box presses continue to be employed. Their use, however, is relatively limited, and the world production of coconut oil is largely obtained by use of continuous mechanical screw presses. In either instance, before processing the copra is passed through a cleaner which removes sand and trash. It is then passed through a crusher which breaks it into small pieces. The broken pieces move through a magnetic separator which disposes of any metal debris. The material is then ground finely and treated.

**Single Pressing**.—The finely ground copra is cooked in steam-jacketed kettles or compartments to a moisture content of about 1.5%. The meat passes from the driers into continuous mechanical screw presses which consist essentially of a cylinder or barrel, in which an impelling worm turns and continuously forces the tempered copra through a small terminal orifice. The barrel is composed of a series of rectangular steel bars, separated by spaces to form slots. Pressure and heat of friction force the oil which escapes through the slots of the barrel. Continuous mechanical screw presses may have a vertical and a horizontal pressing barrel, each operated by a separate motor. In the single type the horizontal barrel performs the entire copra-pressing operation. Continuous mechanical screw presses have a capacity

of copra per 24-hr. day. Before passing to the crude tanks the coconut oil is screened to remove fine particles of ground copra. It is then run through a filter press. The screening process and the filter press cake are returned to the screw presses for re-pressing.

**Solvent Extraction.**—In Europe and the United States some oil is extracted by means of petroleum solvents (hexane) from copra which has been prepressed through large mechanical screw presses. These screw presses, with a capacity of 25-65 tons per day, reduce the oil in copra from 65% to 10% before the cake is prepared for extraction. The oil-bearing material is treated continuously in a countercurrent flow solvent until the oil left in the extracted meal has been reduced to 1%. The solvent is removed from the extracted meal by means of steam-jacketed, agitated conveyers. The solvent oil is recovered by distillation and the last traces of solvent removed by steam distillation of the oil *in vacuo*.

**Copra Meal.**—The meal from pressed cake contains 21.3% oil on the average and 5% to 7% oil. Solvent-extracted cake contains less oil and a proportionately greater amount of protein. The meal is valued as a dairy feed. It is also satisfactory as a supplementary feed for fattening cattle and lambs.

**Coconut Oil.**—The oil is colourless to yellowish in appearance and melts at about 74° F. Crude coconut oil has a characteristic coconut odour. The fatty acids of coconut oil possess a lower molecular weight than those of most other fats. Thus the solubility of their sodium salts and the sulfated fatty acids derived from coconut fatty acids make coconut oil a valuable material for the manufacture of soaps and other products.

Crude coconut oil is the product of refining and deodorizing of coconut oil to remove free fatty acids and flavours. An important use of coconut oil arises from its high percentage of saturated (48%). The resistance of this saturated fatty acid to development of rancidity caused by oxidation prompts confectioners and bakers to use refined coconut oil in coatings and for baked goods and candy which may stand for a relatively long time between manufacture and consumption. Prior to World War I coconut oil had extensive use in margarine manufacture in the United States, but later it was largely displaced by domestic oils. Its use in margarine continues undiminished in Europe and elsewhere. Refined coconut oil is used in the manufacture of margarine and as a cooking fat.

Cooke, *Copra Processing in Rural Industries*, Food and Agricultural Organization of the United Nations, Technical Development Paper no. 63 (1958). (J.N.B.G.; J.K.R.)

**COPROLITE.** The name was originally given by William Smith to certain bodies in the Lias strata of Gloucestershire which formerly had been considered fossil fir cones (see JURASSIC). He showed that they possessed characters which could be explained on the supposition that they were the fossilized remains of reptiles (from Greek *kopros*, "dung," and *lithos*, "stone"). Chemical analysis showed that they were very rich in phosphatic minerals.

They are now known to be the fossilized excreta of a variety of organisms that differ greatly in size and habitat and include aquatic animals, fish, turtles, mammals and reptiles. In age they range from Permian to Pleistocene and have been found in many parts of the world in beds of marine and freshwater shale and limestone, in volcanic ash and in cave deposits.

Coprolites consist principally of tricalcium phosphate. Some contain extraordinarily well-preserved remnants of partially digested food, muscle fibres and the tissues and seeds of identifiable plants. Others contain a profusion of silicified bacterial cells.

**COPTIC CHURCH (COPTIC ORTHODOX PATRIARCHATE OF ALEXANDRIA)**, the chief representative of the Christian church in Egypt. The Copts are a people, the descendants of the original inhabitants of Egypt, as their language is the direct descendant of the ancient Egyptian language.

For the history of the language which may be properly termed "dead" as a spoken language and for the surviving Coptic literature, which is almost entirely religious, see COPTIC LANGUAGE and EGYPTIAN LANGUAGE.

The word Copt is the westernized form of Arabic *qubṭ*, Greek *αἰγύπτιος*, signifying the language and people of Egypt before the Arab conquest in the 7th century A.D. In later times the Muslims of Egypt ceased to call themselves *αἰγύπτιοι* and the word became the distinctive name of the Christian minority. From the 5th century onward this Christian minority belonged to the church which Eastern Orthodox and Roman Catholics term Monophysite (see MONOPHYTES). The church never called itself Monophysite, however; to its members it is simply the Egyptian church, other churches being foreign. In the 19th and 20th centuries some Copts have become Roman Catholics and Protestants, so that the members of the Coptic Church have come to call themselves Coptic Orthodox, in order that they may be distinguished from these Christians and also from the Greek Orthodox of Egypt (for which see ALEXANDRIA, GREEK ORTHODOX PATRIARCHATE OF).

In the 4th and 5th centuries a conflict arose in Egypt between those who spoke Greek and those who spoke Coptic. The relationship between this conflict and the contemporary controversy concerning the person of Christ is very complex, but it is clear that in the 6th century, if not before, the Coptic speakers were all against the Council of Chalcedon (451) while the Greek speakers for the most part supported it. There is a tendency among modern writers to treat this conflict as a political one between nations; but the people involved in the controversy, while it was alive, regarded it as theological. Various attempts were made by the Byzantine emperors and their advisers to bring about a settlement through a compromise formula; but insofar as these attempts meant giving up the authority of the Council of Chalcedon they were opposed by the Greek Orthodox and by the see of Rome. After the Arab conquest of Egypt such attempts ceased. It was then in the interests of the Egyptian Christians that the majority of them should be able to say that their form of Christianity was not the same as the Christianity of the Byzantine empire. The emperors had sought to alter the doctrines of the Coptic Church and to coerce it into union with other Christian churches; the Arab caliphs, although they tended to favour those who adopted Islam, did not interfere so much in the internal affairs of the Christian Church.

The few Chalcedonians left in Egypt were Greeks and were described as Romans or Melchites ("emperor's men"). The theological controversy between the Copts and the Melchites may be thus summarized: The Monophysite (Gr. "one nature") Coptic, Syrian, Armenian and Greek opponents of the Council of Chalcedon believed that their Greek, Roman and other Melchite adversaries, who supported Chalcedon, were preaching two Christs: God and man, instead of one Christ, the God-man. The non-Chalcedonians insisted that in no figure or sense had in reality "God was born" and "God died," and they accordingly suggested that the Chalcedonian formula of the "two natures" of Christ implied a denial of the reality of Christ's birth and death, and thus undermined the essential Christian faith. The Greek Orthodox, on the other hand, accused the Monophysites of denying that the humanity of Christ was temporal real. After the Arab conquest of Egypt the Copts ceased to speak Greek and the language barrier, in addition to the political conflict, gave a fixed form to the controversy, which slowly ceased to arouse interest. It has been described, with good reason, as a matter of phraseology rather than a matter of doctrine in conflict; but it is still a barrier in the way of reunion between the Eastern churches. (For the 5th-6th century Christological controversy, see further COUNCILS, MONOPHYTES, JESUS CHRIST, *The Dogma of Christ in the Ancient Councils*.)

Apart from the questions involved in this particular controversy the Monophysite churches and the Orthodox Eastern Church agree in doctrinal matters. In modern times the Copts and the other non-Chalcedonians have been on the defensive against western influence, both Latin and Protestant, in the near east and in this respect they have found the Greek Orthodox to be their allies.

Arabic is now used in the services of the Coptic Church for the lessons from the Bible and for many of the variable hymns. The part of the service which is not in Arabic consists largely of short refrains which churchgoing people all understand. The response "Lord have mercy" and the hymn "Holy God, holy and strong, holy and immortal, have mercy upon us" are sung in Greek. The Coptic Church uses the liturgies attributed to St. Mark, St. Cyril of Alexandria and St. Gregory of Nazianzus (see *LITURGY*). The service books are written in Coptic (the Bohairic dialect of Alexandria), with the Arabic text in parallel columns.

The Copts have shown little tendency to travel and carry their church with them. There is a Coptic church in Jerusalem and a few other Coptic churches were built in the Holy Land in the 19th and 20th centuries; there is also a Coptic bishopric in Khartoum for Copts living in Sudan. But no considerable body of Copts seems to have settled permanently in western Europe or the new world.

The Ethiopian Church is in full communion with the Coptic Church, having been founded by missionaries from Egypt, and until 1948 it had a Coptic archbishop as its sole bishop. Since 1948 it has had its own Ethiopian catholicos-patriarch, consecrated by and under the spiritual authority of the "pope and patriarch of Alexandria and of the preaching of St. Mark," who is the recognized head of the Coptic Church. The Armenian and Syrian Orthodox Churches also are in communion with the Copts.

The Coptic Church developed a democratic system of government after the 1890s. The finances of the churches and schools and the administration of the rules relating to marriage, inheritance and other matters of personal status among the Copts in Egypt are regulated by the patriarch and the diocesan bishops (of whom there are 12) with the assistance of community councils in which the laity is well represented. When the patriarch dies, an electoral college of which the great majority of members are laymen selects three duly qualified monks as candidates for the office of patriarch. Among these three the final choice is made by lot after prayer. Only a monk of many years' standing can be a candidate for the patriarchate or even become a bishop.

The patriarch resides in Cairo. The church has its own primary and secondary schools in many places in Egypt, as well as a strong Sunday school movement for education in Coptic Church tenets of children unable for any reason to go to Coptic schools. There is an Institute of Coptic Studies in Cairo, a theological college connected with that institute and a Coptic museum. Egypt appreciates the Copts as an important and thoroughly Egyptian element in the community, and the teaching of the Coptic Church has been the basis of the syllabus used in the religious instruction of Christian children in government schools. There are many Copts among government officials and professional men. Nevertheless Copts living in Muslim villages in Upper Egypt have shown a tendency to go over to Islam in the hope of getting work, and in some parts of the countryside the Coptic Church is struggling to keep alive.

**COPTIC LANGUAGE**, the descendant of ancient Egyptian, is called in modern times after the Arabic *qubṭ* (i.e., Egyptian); it is one of the Hamitic languages in origin. Its oldest documents belong to the 2nd and 3rd centuries A.D., being vernacular translations of the Scriptures by native scholars, who were well acquainted with Greek. They wrote their language not in their own current script (demotic) but in the Greek alphabet supplemented by seven symbols taken from demotic.

The vogue of this Coptic language and its dialects became progressively restricted after the Arab conquest of Egypt (A.D. 640). It was finally extinguished in the 17th century, apart from very scanty traces (19th century) in a few small localities in Upper Egypt (*Sa'id*), and except for its survival in the native Christian

church of Upper Egypt in the Bohairic dialect (originally of lower Egypt). The Arabic writer Maqriẓi (15th century) recorded that in his own day Copts in Upper Egypt spoke scarcely anything but Coptic; 200 years later a European traveler, P. Vansleb, found only a single family at the village Zeniya, a little north of Luxor, and one old man who spoke it.

**Classification.**—In word forms and sentence structure Coptic resembles the spoken Egyptian of the new kingdom from which it was derived and does not differ notably from literary demotic. A more popular demotic used Greek letters in which to write horoscopes and magical texts (usually omitting the vowels). The language of these, which has come to be known as Old Coptic, is different from Christian Coptic, being both more archaic and comparatively free from Greek loan words.

Coptic proper is classified into six dialects. Two are from Lower Egypt:

1. *Bashmuric* is unknown except in a few glosses. It appears to have been a pidgin language of mixed Coptic or Egyptian and Greek and was spoken along the eastern outlet of the Nile delta.

2. *Bohairic*, from Arabic *al-buhaira*, was spoken in the western part of Lower Egypt, including Alexandria, the Wādi el-Natrun and Memphis. It was this that later became the churchly and upper-class dialect of the Coptic hierarchy at first at Cairo (in the 11th century) and eventually of Upper Egypt. For a time it must have been current side by side with Arabic in Lower Egypt.

The remaining four dialects are from Upper Egypt:

3. *Fayumic*, spoken along the Nile valley, chiefly on the west bank, was the Arsinoë of the Greco-Roman period; it is linguistically close to Bohairic. But some of the documents from the Fayum show intermixed Bohairic and Sahidic elements. It survived for popular use in private documents as late as the 8th century, having been abandoned for literary use.

4. *Asyūtic* (also called Sub-Akhmimic) in Upper Egypt (around Assiut), is closely akin to Sahidic and Akhmimic. It flourished in the 4th century. In it are preserved a text of the Fourth Gospel and of the Acts, important religious texts of Mani and his disciples, and a number of Gnostic documents, the last in a somewhat different, but related, dialect.

5. *Akhmimic* proper is known from the city Akhmim (Chemmis, Panopolis) of Upper Egypt and its vicinity. There are 4th-century documents in a dialect that must be descended from the same source as Sahidic, but from which its phonological system differs markedly.

6. *Sahidic* (from Arabic *al-sa'id* "Upper Egypt") was originally the dialect of Antinoë and Hermoupolis and the Thebaid, and after the 5th century was the standard Coptic of the whole of Upper Egypt. It was supplanted by Bohairic for religious use after the 11th century. It is richly documented; it has a well-known and extensive vocabulary; and its grammar is that of a pure and early Coptic, being in fact what is usually meant by "Coptic" without qualification.

**Characteristics.**—Notwithstanding Greek and Arabic influence the Egyptian origin of Coptic is clearly seen in its system of sounds, inflections, syntax and vocabulary. Both consonant and vowel systems are rich and varied. The parts of speech are the noun, adjective, pronoun and verb, all of which are inflected; the adverb, conjunction, and preposition are decayed noun forms. There are two genders and two numbers. Roots are preponderantly triconsonantal (e.g., *wnš* "wolf"), exceptions being due to the loss of a laryngeal, the failure to write semivowels (consonantal *i* and *u*), or other uncertainties of the interpretation of the writing. As for syntax, although the so-called "nominal" type of sentence lacking a finite verb, which is characteristic of Egyptian, survived into Coptic, there is an extensively developed system of tenses (as in Greek and Latin). Coptic is further characterized by an increased use of auxiliary verbs and a conjugation system that employs prefixes, a feature found in the Egyptian of the new kingdom.

**Literature.**—Coptic literature (apart from mere business documents and letters in Sahidic and Fayumic expressed in monish language) is almost entirely religious and consists mainly of translations from Greek. Versions from the Old and New Testaments were made into Sahidic, Akhmimic and Fayumic before the Com-

cil of Chalcedon (451). Evidence about Gnostic beliefs, otherwise known chiefly through the attacks of opponents, is provided by the *Pistis Sophia*, extant in the 4th-century Askew Codex of the British museum, and by the texts in the Bruce Codex of the Bodleian library, also of the 4th century. These works are believed to be translations dating from the 3rd century and belong to an ascetic sect of the Gnostics which rose in Egypt itself. There is abundance of apocryphal works, apocalypses, patristic writings from those of Athanasius to those of the Council of Chalcedon (451), homilies, lives of saints and anecdotes of holy men, acts of martyrs, extending from the persecution of Diocletian (reigned 284–305) to that of the Persians in the 7th century, and lives of later ascetics and martyrs, to the 14th century. Unless some of the Egyptian *acta sanctorum et martyrum* should prove to have been originally written in Coptic, almost the only original works in that language of any importance are the numerous sermons and letters of Shenute, the long-lived and now celebrated monk of Atrepe near Akhmim. These works were written in the Sahidic dialect in the 4th and 5th centuries. After the Arab conquest, as a defense to the threatened church language and nationality, versifications of the Proverbs, of Solomon's Song and of various legends were composed, with other religious songs. They are mostly antiphonal, the numbers of stresses in a line marking the rhythm. There is no musical notation in the manuscripts, but traditional church tunes are generally referred to or prescribed for the songs. Of secular literature strangely little existed or at least has survived; only a few magical texts and fragments of a medical treatise, of the story of Alexander and of a story of the conquest of Egypt by Cambyses are known. According to all evidence available, the Coptic portion of the great library in the monastery of St. Marcarius, made after its restoration in the ninth century, contained only religious books. See also EGYPTIAN LANGUAGE.

**BIBLIOGRAPHY.** —G. Steindorff's *Lehrbuch der koptischen Grammatik* (1952) is a good up-to-date work, devoted chiefly to Sahidic. On the other dialects see W. Till, *Koptische Dialektgrammatik* (1931). (Cf. J. Simon, *Les dialectes coptes*, Actes IV Congrès internat. de Linguistes, 1936, pp. 182–186.)

## COPTOS: see QFT.

**COPYHOLD**, in early English law, a form of landholding defined as a "holding at the will of the lord according to the custom of the manor." Its origin is found in the occupation by the villeins or non-freemen of portions of land belonging to the manor of a feudal lord. The portion reserved for the lord was cultivated by labourers who also were allowed to cultivate portions of the land for their own use. In the course of time this privilege grew into an occupation by right. This type of interest in land was abolished in England in the Law of Property act of 1925. See MANOR; SERFDOM AND VILLEINAGE.

**COPYRIGHT** is the term generally used to designate the rights secured by the laws of civilized countries to authors of literary, dramatic, musical and artistic works, to protect against unauthorized copying of their works. The growth of the law of copyright protection closely followed the development of means

and media of reproduction, performance, exhibition, presentation and representation. Literary copyright received its great impetus from the invention in Europe of printing by movable type; artistic copyright from the expanded use of engravings and lithographs. Photography, sound recordings, motion pictures (silent and sound), radio and television have all affected copyright.

## UNITED STATES

Prior to any copyright legislation, protection—known as "common-law copyright"—was afforded to authors on common-law and equitable principles. Such protection, although abolished by statute in Great Britain and the dominions, is preserved in the United States for unpublished works. Thus the United States has a dual copyright system, with prepublication protection dependent substantially on common-law principles and postpublication protection available only under federal statutory copyright.

At common law, protection accrues automatically upon the creation of the work, vests in the author regardless of his nationality or the place of the creation of the work and includes full control over all uses of the work prior to publication. Upon publication (meaning the sale or general distribution of copies and not public performances, presentations, broadcasts and the like), common-law copyright ends, and protection is available thereafter only under the federal copyright statute.

Statutes for the protection of copyright were among the earliest laws enacted in the United States. Noah Webster, interested in protecting his *American Spelling Book*, promoted copyright legislation and has been called the father of such legislation in the U.S. On May 2, 1783, congress, which under the Articles of Confederation had no power over copyright, recommended to the states that they enact legislation to protect the authors or publishers of new books. From 1783 to 1786, all of the 13 original states except Delaware adopted copyright statutes patterned after the English statute of Anne of 1710. The federal constitution ratified in 1788 empowered congress "To promote the Progress of Science and useful Arts, by securing for limited Times to Authors and Inventors the exclusive Right to their respective Writings and Discoveries." In 1790 congress enacted the first federal copyright statute, giving protection to books, maps and charts, by authors who were citizens or residents of the United States, for a term of 14 years with the right of renewal for 14 years more. The author or his assigns were given the sole right to print, reprint, publish and vend the copyrighted work.

Gradually, during the 19th century, federal statutory copyright was extended to musical, dramatic and various forms of artistic works, and the scope of protection was broadened. Ineligible for federal statutory protection, however, were the works of nonresident foreigners. Finally, in 1891, after many years of controversy, such copyright protection was authorized for the works of foreign authors whose countries granted similar protection to U.S. authors; but to overcome the objection of the American printing trades, which feared their employment would be lost to lower-cost printers in other countries, the requirement was imposed that copies of books, photographs, chromos or lithographs must be manufactured in the U.S., and the importation of copies or plates made elsewhere was prohibited with minor exceptions. In 1909 all prior copyright statutes were replaced by a single comprehensive copyright act. In 1912, the act was amended to authorize expressly the copyrighting of photoplays and motion pictures other than photoplays. The 1909 act, as amended, was codified and re-enacted in 1947 as title 17 of the U.S. code, entitled "Copyrights." Title 17 of the code was amended after 1947 in several particulars.

**U.S. Copyright Law.**—The Copyright law provides copyright protection for "all the writings of an author," specifically enumerating books, periodicals, lectures, sermons or addresses prepared for oral delivery, dramatic or dramatico-musical compositions, musical compositions, maps, works of art, reproductions of works of art, drawings or plastic works of a scientific or technical character, photographs, prints and pictorial illustrations and motion pictures. Phonograph and other sound recordings are not copyrightable under the statute. The copyright owner is given the exclusive right to use the copyrighted work in several ways, vary-

ing to a considerable extent with the type of work involved. The exclusive right to print, reprint, publish, copy and vend is applicable to all types of copyrighted works; the exclusive right to translate or to make any other version applies only to a literary work; the exclusive right of public delivery for profit and of recording applies to a lecture, sermon, address or similar production, or other nondramatic literary work; to a drama attaches the exclusive right of converting it into a nondramatic work, of public performance and of recording; to a musical composition the exclusive right of arrangement and adaption, of public performance for profit and of recording, etc. To be copyrightable, a work must be original (in the sense that it is not copied from another work except where it is an authorized new version) but need not, as in the case of a patent, be novel. Copyright does not protect ideas or titles. Infringement exists only when there is substantial unauthorized copying and not independent creation by another. Special provision is made for a compulsory licence to record musical works: when the copyright owner has made or authorized a recording of a musical work for mechanical reproduction, as on a phonograph record, any other person may make a similar use of the work upon payment to the owner of a statutory royalty of two-cents per part manufactured.

Copyright is secured by publication of the work with the notice required by the statute, and this notice must appear in each copy of the work published in the United States by authority of the copyright owner. Such publication without the notice places the work in the public domain. The form of notice, which is required for literary, musical and dramatic works and may be used on any other works, consists of the word "Copyright" or the abbreviation "Copr." or the symbol ©, accompanied by the name of the copyright owner and the year in which the copyright was secured; e.g., "© 19—, by John Doe." For maps and artistic and pictorial works, however, because the longer form of notice on the face of such works might tend to detract from their aesthetic appeal, the notice may consist of the copyright symbol © accompanied by the initials or other mark of the copyright owner, provided that the owner's name appears in some accessible place on the copies or on their permanent base or mounting.

After copyright has been secured by publication of the work with the required notice, copies of the work are to be deposited in the U.S. copyright office together with an application and fee for registration of the copyright claim. The copies deposited are made available to the Library of Congress. Registration of the copyright claim is a prerequisite to any action in the courts for the infringement of the copyright. The copyright office issues a certificate of registration which is prima-facie evidence in any court of the facts stated in the certificate. The copyright endures for 28 years from the date of first publication and may be renewed for a second term of 28 years. Renewal is secured by filing an application in the copyright office during the last year of the original 28-year term. In the special cases of posthumous works, composite works (such as periodicals or encyclopaedias, in which the work of a number of authors is collected) and works made for an employer for hire, anyone owning the copyright may obtain the renewal. Generally, however, the right to secure the renewal belongs only to the author; or if the author is deceased, then to his widow or children; and if there is no surviving widow or child, then to the author's executor or in the absence of a will his next of kin. Such expectancy in the renewal term may be expressly assigned in advance, but such an assignment is effective only if the assignor would otherwise have the right to secure the renewal at the time of renewal.

The typesetting, printing and binding of printed books or periodicals in the English language must be done in the United States. However, a book or periodical in the English language first published abroad will be given ad interim copyright protection for five years if a copy is deposited and the copyright registered in the U.S. copyright office within six months after its publication. When ad interim copyright is so secured, not more than 1,500 copies of the book may be imported into the United States during the five years. If copies of the book are manufactured and published in the United States at any time within the five-year period,

the deposit and registration of that American edition will extend the copyright to the full term of 28 years with the right of renewal for another 28 years.

Works of specified classes not reproduced in copies for sale—lectures, sermons and addresses prepared for oral delivery, dramatic or dramatico-musical compositions, musical compositions, works of art, drawings or plastic works of a scientific or technical character, photographs, motion pictures—are eligible for statutory copyright prior to publication by registration and deposit in the copyright office. The initial 28-year copyright term therein runs from the date of registration, and the securing of such statutory copyright terminates common-law copyright. However, books, periodicals or other nondramatic literary material not prepared for oral delivery, maps, reproductions of works of art, prints and pictorial illustrations are not eligible for statutory copyright prior to publication, and hence any prepublication protection for such material can be based only upon common-law copyright.

The statute provides that a copyright may be assigned or mortgaged by an instrument in writing and may be bequeathed by will. Assignments are to be recorded in the copyright office. Records of all copyright registrations and recorded assignments and other instruments relating to copyright are maintained in the copyright office where they are open to public inspection. Upon request, the copyright office will conduct a search of its records and supply a report of the copyright information shown by its records regarding any particular work or works, for a statutory fee.

In 1955 the copyright office undertook a program of studies of the U.S. copyright law, which had been amended only slightly since 1909. Thirty-five studies were prepared and distributed to a Panel of Consultants on General Revision and other interested persons. In 1961 the copyright office issued a report containing its tentative recommendations for revision of the law. General revision bills were introduced in congress in 1964, 1965, and 1967, hearings were held and amended bills were reported by the house judiciary committee; the bill as amended was passed by the house on April 11, 1967, and referred to the senate judiciary committee. Meanwhile, renewed copyrights which otherwise would have expired were extended. (Ar. F.; Ha. G. H.)

## GREAT BRITAIN AND THE COMMONWEALTH

Up to 1911 the law of copyright in England had been the subject of a network of statutes, each relating to a particular aspect of the subject. Substantially the whole of the law was for the first time brought within the bounds of a single statute by the Copyright act, 1911, later replaced by the Copyright act, 1956. Some account of the earlier statutes may be useful before summarizing the law as it stands under the Copyright act, 1956. The English law of copyright applies to Scotland and Northern Ireland without modification. (See also PUBLISHING: *Printing and Publishing in Modern Europe*.)

**Historical Development.**—Literary copyright was protected by the Literary Copyright act, 1842, which provided that the copyright in every book published in the life of the author should endure for the life of the author and for seven years after his death, or for 42 years, if longer. Provision was made for registration at Stationers' hall, and no action for infringement could be brought without prior registration. "Book" was defined as including volume, part or division of a volume, pamphlet, sheet of letterpress, sheet of music, map, chart or plan separately published. Engravings were protected by three acts, the Engraving Copyright acts of 1734 and 1736 and the Prints Copyright act 1777, and were entitled to copyright for 28 years from publication. Registration was not required but the name of the proprietor and the date of the first publication had to be engraved on the plate and printed on each print. Copyright was given to sculptors by an act of 1814, provided that the name of the author and date of issue to the public appeared on each work. The last class to be protected was artists and photographers, whose protection was first secured by the Fine Arts Copyright act, 1862. The sole right to perform dramatic pieces was secured by the Dramatic Copyright act of 1833 and to play musical works by the act of 1842.

The Copyright act of 1911 repealed substantially the whole of the earlier copyright statutes. It provided that no person should be entitled to copyright except in accord with its provisions, so that the common-law copyright previously recognized in unpublished works was no longer in force. Copyright in published and unpublished works was in fact assimilated except for the provisions limiting the area and term of protection.

It is also important to observe that after 1911 registration at Stationers' hall was no longer necessary, so that copyright was thereafter secured to the author by the act of creation and no formality of any kind was acquired. The Copyright act, 1956, repealed the Copyright act, 1911, save for the provisions relating to the delivery of copies of books to the British museum and other libraries.

The Copyright act, 1956, besides re-enacting the main provisions of the Copyright act, 1911, created copyright in several fresh forms of endeavour, namely, in sound recordings, motion-picture films, television and sound broadcasts and in new editions of literary works. It also widened the scope of the protection given to all works, e.g., by making it an infringement to broadcast a work or cause it to be transmitted to subscribers to a diffusion service.

**Subject Matter of Copyright.**—Copyright, as provided by part i of the 1956 act, subsists in every original literary, dramatic, musical and artistic work. These expressions are defined in the act. It has been decided that the word "literary" does not connote style or literary finish but is used merely to indicate written or printed matter. The only limit would appear to be that the work in which copyright is claimed must be sufficiently extensive to have demanded some skill in composition. Copyright protection is given not to ideas but to literary forms. Compilations such as directories, dictionaries and also tables, which are included as literary works, are in a rather special position. The originality which entitles these to copyright resides not in any literary form but solely in the labour and skill which the author has expended in collecting, sifting and arranging information or in making calculations so as to produce the resulting work. Though much of the matter contained in such works may of itself be unoriginal, that which is protected is the product of the compiler's individual labour and skill in collation or calculation.

On the other hand, mere cutting down of a standard work into a form suitable for schools has failed to receive protection. There must be real exercise of labour and skill and not a mere commonplace selection of ordinary items of information. Artistic works are defined as including paintings, drawings, sculptures and photographs and engravings, and works of artistic craftsmanship and architectural works of art. An engraving or photograph may be made of a picture and it has been decided that such a work is original though depicting the same object or scene as the picture. The definition of dramatic work includes choreographic work or entertainment in dumb show, if reduced to writing. This definition excludes mere "gag" which has no fixed form, but it would include, for example, the movements of a musical-comedy chorus, which are often represented for the producer by a rough sketch or by symbols.

Under part ii of the Copyright act, 1956, copyright subsists in sound recordings, motion-picture films and television and sound broadcasts made by the British Broadcasting corporation or the Independent Television authority. It also subsists in every published edition of a literary, dramatic or musical work provided it does not reproduce the typographical arrangement of a previous edition.

**Rights of Owners of Copyright.**—Copyright is the exclusive right to do certain acts in relation to the work, known as "restricted" acts. In the case of literary, dramatic and musical works, the restricted acts are those of reproducing the work in any material form, publishing it, performing it in public, broadcasting it or causing it to be transmitted to subscribers to a diffusion service, and making any adaptation of the work. In the case of an artistic work, the restricted acts are reproducing the work in any material form, publishing it, including it in a television broadcast and causing a television program which includes the work to be transmitted to subscribers to a diffusion service. It is an infringement

to do or to authorize another to do any of the restricted acts in relation to the work without the permission of the copyright owner. Section 5 (1) of the 1956 act provides for the liability of persons dealing with articles which they know to infringe copyright by selling such works or by distributing or exhibiting them by way of trade. It is also an infringement of copyright to import for sale into the country any work which to the importer's knowledge would infringe copyright if made there. An additional protection to copyright owners is the provision in s. 18 (1) that any copy of a work which is an infringement of the owner's copyright is the property of the owner. The owner can therefore bring an action for recovery or damages against anyone in possession or who has been in possession of such copies.

There are three exceptions to the general rule that the author is the owner of the copyright: (1) Where a literary, dramatic or artistic work is made by the author in the course of his employment by the proprietor of a newspaper or periodical under a contract of service for publication in a newspaper or periodical, the proprietor is entitled to the copyright insofar as it relates to newspapers and periodicals. For all other purposes, however, the author remains the owner of the copyright. (2) A person who commissions any photographs, portrait, drawing, painting or engraving for good consideration is entitled to the copyright. (3) If a work is made by the author in the course of his employment under a contract of service, the copyright belongs to his employer.

The owner of copyright can assign his right or may grant interests therein by way of licence. He may assign any separate part of the rights given him by the act and he may assign his rights for a limited area or for a limited period of time. The assignee is in the position of an owner in respect of the right assigned. No assignment is effective unless it is in writing signed by or on behalf of the assignor. The 1956 act provided for the establishment of a performing-rights tribunal to decide disputes between licensing bodies and persons requiring licences or organizations claiming to represent such persons.

**Duration of Copyright Protection.**—Copyright in published literary, dramatic and musical works endures for 50 years from the year of the author's death. The period is the same for artistic works, except in the case of photographs, and of engravings not published at the death of the author, copyright in which runs for 50 years from the year of first publication. Copyright in works falling within part ii of the 1956 act lasts for varying periods dependent on the nature of the work in question, the most usual period being 50 years from the year of first publication. In the case of new editions the copyright lasts for 25 years from the year when the new edition was first published.

**Infringement of Copyright.**—Infringement of copyright under the act of 1956 is committed by any person who does or authorizes another to do any of the restricted acts in relation to the work in question without the licence of the copyright owner. As under the old law, it is essential for the owner of copyright to prove that a defendant has either copied his work or copied something which was itself a copy. Resemblance, though it may often lead to the inevitable conclusion that the defendant has in fact seen the plaintiff's work and so be excellent evidence that copying has occurred, is not in itself sufficient to substantiate a claim for infringement.

One of the most difficult questions which the courts have to determine is whether a defendant has so far copied the plaintiff's work that he can be said to have created a colourable imitation of it, or whether he has taken the idea only and clothed it in a new literary or artistic form. This problem arises forcibly in the case of plays which are alleged to infringe the copyright in a novel and in the case of motion-picture films. Because of the differences between the forms of expression in such cases, it is unlikely that much literal copying will be discoverable. The result of decisions on the subject appears to be that while the mere taking of a plot is not sufficient in itself to constitute an infringement, yet this, coupled with a close resemblance of situations and incidents, even without the taking of actual words or phrases, will be enough to give rise to a cause of action. In dealing with the question of colourable imitations of artistic works the following test has been

suggested: "A copy is that which comes so near the original as to suggest that original to the mind of every person seeing it."

The act provides that it is an infringement to take "a substantial part" of the original work. Cases dealing with the earlier acts which, though they did not use this exact phrase, were held to have implied it, have decided that "substantial" does not refer to quantity alone but also to the importance of the part taken in relation to the whole; a few bars out of a long piece of music may contain the essential melody or a few lines may hold the real beauty of a poem, and the taking of these bars or lines would certainly be prohibited.

A further question which arises is how far copyright can be infringed by reproductions in a different form of art. Under the act of 1911 it was an infringement to reproduce the copyright work "in any material form whatsoever." By virtue of these words a *tableau vivant* was in *Bradbury Agnew and Co. v. Day*, 32 Times L.R., 349, held to infringe the copyright in a picture; and by the decision of the house of lords in *King Features Syndicate, Inc. v. O. and M. Kleeman, Ltd.*, 58 Rep. Pat. Cas., 57, 207, it was clear that three-dimensional articles such as sculptures and two-dimensional works such as drawings or pictures might be infringements of one another respectively. Under the 1956 act it is necessary to contrast the words of s. 3 (5) (a), whereby "reproducing the work in any material form" is a restricted act, with the provisions of s. 9 (8), according to which "the making of an object of any description, which is in three dimensions, shall not be taken to infringe the copyright in an artistic work in two dimensions, if the object would not appear, to persons who are not experts in relation to objects of that description, to be a reproduction of the artistic work." The wide definition of artistic works in the 1911 act included works which were registrable under the Patents and Designs act, 1907, as industrial designs. An overlap was thus created between the two acts. This was dealt with by s. 22 of the Copyright act, 1911, which provided that if these works were used or intended to be used as models or patterns to be multiplied by an industrial process, the Copyright act should not apply to them, and such works could therefore enjoy only the protection given by the Designs act, for which they would require to be registered.

Under the 1956 Copyright act a similar overlap would still exist but for s. 10 of this act, which eliminates the factor of intention, and instead of depriving such works of copyright provides that the copyright in them shall not be infringed if they have been registered under the Registered Designs act, 1949, or if, being capable of registration, articles to which they were applied industrially have been sold by the copyright owner or with his consent. Section 10 applies to all works after June 1957 but not to works made before that date, in respect of which the provisions of s. 22 of the Copyright act still apply.

In *Dorling v. Honnor*, 1964, Rep. Pat. Cas., 160, s. 10 was applied, and it was held that plans, which are specifically excluded and therefore not capable of registration as designs, were infringed by reproduction in three-dimensional forms despite manufacture on an industrial scale and sale by the copyright owner.

**Permitted Reproductions.**—The Copyright act, 1956, expressly provides that certain acts shall not constitute an infringement of copyright. There is a general provision that any fair dealing with a work for purposes of criticism or review or for the purpose of reporting events in a newspaper, magazine or periodical or by means of handwriting or in a motion-picture film shall be allowed. Obviously "fair dealing" is difficult to define, but it would seem that the question of whether the two works compete is of importance in judging the fairness of the reproduction. A liberty of a similar nature is the publication of short passages from published literary works in collections for the use of schools. There are also special exceptions in the case of reproduction for the purpose of judicial proceedings and, in certain cases, by librarians.

There is a further provision which was also intended to protect the innocent, since it provides that if a defendant proves that at the date of the infringement he was not aware of and had no

reasonable ground for suspecting that copyright subsisted in the work the plaintiff shall not be entitled to damages. It was held, however, in *Byrne v. Statist*, 1914, 1 K.B. 622, that this provision did not assist a defendant who thought he had a licence to copy but was innocently mistaken. Since any work may be the subject matter of copyright, it is very difficult for any defendant to prove that he had no ground for suspecting that any particular work was covered, so that the section does not in practice afford much protection.

**Commonwealth.**—The scheme of the Copyright act of 1911 was that it should extend throughout the dominions as one comprehensive code. The act initially applied to British possessions but not to the self-governing dominions. It was provided that either the act might be declared to be in force in such a dominion by its own legislature or that, if a self-governing dominion enacted a similar act, the secretary of state for the colonies might by certificate cause the imperial act to apply to the colony, or, if the dominion legislature did not go so far in following the imperial act but gave adequate protection to British subjects residing elsewhere, an order in council could give protection in Britain to the subjects of that dominion. The dominions took different courses. Australia adopted the act but with certain modifications. New Zealand and Canada adopted their own copyright acts, but in both cases certificates were given by the secretary of state for the colonies. By orders in council made from time to time under the provisions of s. 28 of the act of 1911, that act was extended to certain protectorates. The 1956 act does not have such a wide scope territorially. It does not extend automatically to the colonies, though it may be so extended by order in council to protectorates. (F. E. S. J.; A. D. R.-C.)

## INTERNATIONAL COPYRIGHT

The early copyright laws of all countries limited protection to their own nationals or residents. The first International Copyright act of Great Britain was passed in 1838, and it was not until 1891 that the United States passed a statute enabling qualified nonresident foreign authors to have their works protected under U.S. copyright law. The international copyright relations of most countries are governed by multilateral conventions, the earliest being the Bern union of 1886, which has been periodically revised. More than 40 nations have adhered to one or the other of the latest revisions—the Rome revision of 1928 or the Brussels revision of 1948. The Copyright act of the United Kingdom, as revised in 1956, conformed the British domestic law to the requirements of the Brussels revision.

The United States has never been a party to the Bern union, but U.S. works are protected in Bern union countries if published in one of those countries simultaneously with their publication in the United States. Most U.S. books and musical compositions are simultaneously published in both the United States and Canada in order to ensure Bern protection. The most recent multilateral copyright treaty is the Universal Copyright convention, adopted in Geneva in 1952 and adhered to by both the United States and the United Kingdom. In addition to these world-wide conventions, 17 countries of the western hemisphere, including the United States, have adhered to the Buenos Aires convention of 1910. As of the later 1960s, there were no copyright relations between the United States and the Soviet Union, the People's Republic of China, Egypt, Iran, Turkey and Venezuela.

**The Bern Convention.**—The core of the Bern convention is its provision that each of the contracting countries shall provide automatic protection for works first published in other countries of the Bern union and for unpublished works whose authors are citizens of or resident in such other countries.

Each country of the union must guarantee to authors who are nationals of other member countries the rights which its own laws grant to its nationals. If the work has been first published in a Bern country but the author is a national of a nonunion country, the union country may restrict the protection to the extent that such protection is limited in the country of which the author is a national (art. vi). As of the early 1960s, this retaliatory provision had not been invoked. The works protected by the

Rome revision of 1928 include every production in the literary, scientific and artistic domain, regardless of the mode of expression, such as books, pamphlets and other writings; lectures, addresses, sermons and other works of the same nature; dramatic or dramatico-musical works, choreographic works and entertainments in dumb show, the acting form of which is fixed in writing or otherwise; musical compositions; drawings, paintings, works of architecture, sculpture, engraving and lithography; illustrations, geographical charts, plans, sketches and plastic works relative to geography, topography, architecture or science. It also includes translations, adaptations, arrangements of music and other reproductions in an altered form of a literary or artistic work, as well as collections of different works. The Brussels revision of 1948 added cinematographic works and photographic works. In addition, both the Rome and Brussels revisions protect works of art applied to industrial purposes so far as the domestic legislation of each country allows such protection.

One of the controversial features of the Bern convention is the protection of so-called "moral rights." The Rome revision provides that, independently of the author's copyright and even after transfer of such copyright, the author shall have the right to claim authorship of the work, as well as the right to object to any distortion, mutilation or other modification of the work which would be prejudicial to his honour or reputation. It permits every country, however, to determine the conditions under which these rights shall be exercised and the means of redress for safeguarding them (art. vi). The Brussels convention expressly provides that these rights shall continue after the author's death at least until the expiration of copyright and shall be exercisable by the persons or institution authorized by the domestic legislation of the country where protection is sought.

The term of copyright in the Rome revision for works other than photographic works, posthumous works, anonymous and pseudonymous works is the life of the author plus 50 years, but it was recognized that some countries might have a shorter term. With respect to works originating in such countries, the shorter term provided by their law governs in all other countries even though the latter have a longer term of protection. U.S. works first published in Canada (a Bern country) enjoy (in all Bern countries) the Canadian term of copyright, which is life plus 50 years, although the United States term of 56 years may expire sooner. In the case of works of joint authors, the term is measured from the date of the death of the author who died last. The Brussels revision of 1948 requires a minimum term of protection of the life of the author plus 50 years, provided that if a particular country grants a longer term its nationals cannot claim a term longer than life plus 50 years in countries which limit copyright protection to that period, and in no event may the term be longer than that in the country of origin. The Brussels revision permits domestic legislation to fix the term of copyright for cinematographic and photographic works and provides for a term of 50 years from the date of publication in the case of anonymous and pseudonymous works where there is doubt about the author's identity. The term for posthumous works is 50 years after the death of the author (art. vii of both revisions).

Both revisions protect the right of making translations (art. viii). With respect to articles in newspapers, news items have no protection at all; articles on current economic, political or religious topics may be copied by the press unless the reproduction is expressly forbidden, but the source from which they are copied must be clearly indicated (art. ix).

The specific rights accorded to authors are more clearly set forth in the Brussels revision than in the Rome revision. Authors of dramatic, dramatico-musical or musical works are guaranteed the exclusive right of authorizing the public presentation and performance of their works, as well as their public distribution by any means (art. xi). This protection is subject to the limitation that with respect to the right of radio diffusion or of communication to the public by any other means of wireless diffusion of signs, sounds or images, or the communication to the public over wires or loudspeakers, each country may determine the conditions under which the rights apply; provided, however, that such

domestic legislation must not be prejudicial to the moral right of the author or to his right to obtain just remuneration which, in the absence of agreement, shall be fixed by competent authority (art. xi). Such rate-fixing bodies are provided for in the laws of Great Britain, Canada, Australia and Turkey.

Additional rights are the right of public recitation and the exclusive right of authorizing adaptations, arrangements or other alterations (art. xi, xii). Authors of musical works have the exclusive right of authorizing the recording of their works and the public performance of such recordings, subject to domestic legislation which must not be prejudicial to the author's right to obtain just remuneration (art. xiii). Authors of all works have the exclusive and absolute right of authorizing the making, distribution and presentation of motion pictures (art. xiv).

The Brussels revision introduced a new doctrine called the *droit de suite*, which safeguards the inalienable right of an author to an interest in any sale of his work of art or original manuscript subsequent to the first disposal of the work by the author. In spite of the express grant of this right, it is not mandatory but exists only where enacted by domestic legislation. Such legislation may name the persons or institutions who become the beneficiaries of this right after the author's death as well as indicate the procedure for collection and the amounts to be collected (art. xiv).

The convention established an international office under the authority of the Swiss government to examine copyright questions and to publish a periodical report on the current changes in the law of copyright (art. xxi). Nonmember states may join the union by giving notice of their accession in writing to the Swiss government (art. xxv). In the early 1960s the following countries adhered to the Rome revision but not to the Brussels revision: Australia, Bulgaria, Canada, Ceylon, Czechoslovakia, Denmark, Finland, Federal Republic of Germany, Hungary, Iceland, Japan, Lebanon, Netherlands, New Zealand, Norway, Pakistan, Poland, Rumania, Sweden and Syria.

The following countries adhered to both Rome and Brussels: Austria, Belgium, Brazil, Denmark, Finland, France, Greece, Holy See, India, Republic of Ireland, Israel, Italy, Liechtenstein, Luxembourg, Monaco, Morocco, Norway, Portugal, Spain, Sweden, Switzerland, Tunisia, United Kingdom and Yugoslavia (subject to reservation with respect to translations into the national languages of Yugoslavia).

Cameroon, Congo (Brazzaville), Congo (Kinshasa), Cyprus, Dahomey, Gabon, Ivory Coast, Mali, the Philippines, Senegal, Turkey and Upper Volta have adhered only to the Brussels revision, Turkey taking a reservation with respect to the right of translation.

**The Universal Copyright Convention.**—The Universal Copyright convention of 1952 (U.C.C.), sponsored by the United Nations Educational, Scientific and Cultural organization, differs from the Bern convention in two important respects: (1) it does not provide for automatic copyright protection without formalities (although it limits formalities to a prescribed form of copyright notice indicated below); (2) it does not require adhering countries to ensure any minimum basis of protection to authors of other countries so long as domestic authors are not accorded more favourable treatment, except that all adhering countries must grant an exclusive right of translation for a seven-year period, subject to a compulsory licence under certain circumstances for the balance of the term of copyright. In addition, the minimum term of copyright in member countries (except for photographic works and works of applied art, which have a ten-year term) must be the life of the author plus 25 years. However, if the term of protection in any contracting state on the effective date of the convention in that state is less than life of the author plus 25 years, these shorter periods of protection will control, provided that the term of protection for any class of work shall not be less than 25 years from the date of first publication (art. iv). The U.C.C. thus depends on national treatment for the duration of protection of a work, unlike the Brussels revision of the Bern convention which requires a minimum term of the life of the author plus 50 years.

The only formality permitted is a copyright notice in all copies of the work, consisting of the symbol ©, the name of the copyright

owner and the year of first publication. The place of notice is not prescribed but the notice must be placed in such a manner and location as to give reasonable notice of the claim of copyright (art. iii). If the notice is properly given and the work is first published in any member country, each other member must accord the same protection to the author as it accords to domestic works first published by its own citizens (art. ii). However, each country may require other formalities for works first published in its territory or for works of its nationals wherever published (art. iii). Like the protection accorded by the Bern convention, photographs and works of applied art are protected only in those member countries which protect them by domestic legislation.

The convention did not abrogate any other multilateral or bilateral conventions or arrangements between two or more member states. Where there are any differences, the provisions of the

Universal Copyright Convention are to prevail except as regards the Bern convention, which takes priority over the U.C.C., and conventions or arrangements between two or more American republics.

As of the later 1960s, 50 countries had ratified or acceded to the U.C.C., including both the United States (which adhered in 1954) and the United Kingdom (which adhered in 1957). These countries were: Andorra, Argentina, Austria, Belgium, Brazil, Cambodia, Canada, Chile, Costa Rica, Cuba, Czechoslovakia, Denmark, Ecuador, Finland, France, Federal Republic of Germany, Ghana, Greece, Guatemala, Haiti, Holy See, Iceland, India, Republic of Ireland, Israel, Italy, Japan, Laos, Lebanon, Liberia, Liechtenstein, Luxembourg, Malawi, Mexico, Monaco, New Zealand, Nicaragua, Nigeria, Norway, Pakistan, Panama, Paraguay, Peru, Philippines (which adhered to and later denounced the

**Buenos Aires Convention.**—The Buenos Aires convention of 1910 comprises 17 western-hemisphere countries including the United States. Authors of member states, whether nationals or domiciled foreigners, are assured exclusive power of disposing of their literary and artistic works, of publishing, assigning, translating and reproducing them in any form whether wholly or in part (art. iv).

Although the convention appears to provide for protection of the reproduction rights of authors, two cases in the United States have held that, with respect to musical compositions, in the absence of a specific presidential proclamation for the country concerned relating to mechanical reproduction rights, the Buenos Aires convention does not secure the right of mechanical reproduction to nationals of other member countries (*Todamerica Musica, Ltda. v. Radio Corporation of America*, 171 F. 2d 369 [1938]; *Portuondo v. Columbia Phonograph Co.*, 81 F. Supp. 355 [1937]).

The Buenos Aires convention has eliminated all formalities except those required by the country of origin, provided however that a statement in the work indicates the reservation of the property right (art. iii). Copyright protection obtained in one member country secures protection in all other member countries. Authors enjoy in the different signatory countries the rights granted by the laws of those countries, not to exceed the term of protection in the country of origin (art. vi). Protection cannot exceed that granted by the country in which it is claimed.

Translations are protected as original works (art. iv and ix). The country of origin is the convention country of first publication, and if a simultaneous publication appears in several signatory countries the country which fixes the shortest period of protection is deemed the country of origin. The confiscation of publications infringing copyright is provided for (art. xiv).

The members of the Buenos Aires convention in the early 1960s were: Argentina, Bolivia, Brazil, Chile, Colombia, Costa Rica, Dominican Republic, Ecuador, Guatemala, Haiti, Honduras, Nicaragua, Panama, Paraguay, Peru, the United States and Uruguay. Nine of these countries were also members of the Universal Copyright convention: Argentina, Brazil, Chile, Costa Rica, Ecuador, Haiti, Nicaragua, Paraguay and the United States.

**Place and Length of Copyright.**—The table shows, for each country listed, the office (if any) charged by statute with responsibility for copyright matters (or which is the legal depositary of copyrighted works) and the duration of the copyright term in years as applied to published works. (In some countries a shorter duration applies for photographic works, works of applied art, anonymous, pseudonymous and posthumous works, and works by artificial legal entities such as corporations.) (H. FN.)

**COQUELIN, (BENOÎT) CONSTANT** (1841-1909), French actor, known as Coquelin aîné to distinguish him from his brother (see below), was born at Boulogne on Jan. 23, 1841, the son of a pastry cook. He studied acting at the Conservatoire in 1859 and on Dec. 7, 1860, made his debut at the Comédie Française as the comic valet in Molière's *Dépit amoureux*. At the age of 23 he was a full member of the Théâtre Français (Comédie Française). Mascarille in Molière's *Étourdi* and Figaro, comic valets of brilliant exuberancy, were his greatest parts in the classical repertory, but he did not confine himself to the drolleries and effronteries of agile servants. He could also be delicate and pathetic when he played Pierre in Théodore de Banville's *Gringoire* (1866), and a romantic lover in the title role of Charles Lomon's *Jean Dacier* (1877). The old Alsatian schoolmaster in Erckmann-Chatrian's *Ami Fritz* (1876) was likewise within his range, as well as the chief in Octave Feuillet's *Chamillac* (1886). Coquelin was equally at home in prose tirades, which he could build to an artful climax, and in the delivery of verse, which he handled with superb virtuosity.

In 1886 he resigned his position at the Comédie Française because he intended to tour in Europe and the United States, rejoining the Comédie in 1890. Two years later he left the House of Molière for good and toured the European capitals with a company of his own. He was a member of the Renaissance theatre in Paris from 1895 until 1897, becoming in the latter year director of the Théâtre de la Porte St. Martin, where he created Rostand's *Cyrano* (1897). In 1900 he toured in America with Sarah Bernhardt. During his last years he acted on the boards of the Théâtre Sarah Bernhardt. He died on Jan. 27, 1909, while rehearsing for Rostand's *Chantecler*. Coquelin aîné was the author of three treatises on the craft of the actor: *L'Art et le comédien* (1880), *Les comédiens par un comédien* (1882) and *L'Art du comédien* (1894).

His younger brother, ERNEST ALEXANDRE HONORÉ COQUELIN (1848-1909), called Coquelin cadet, was a member of the Comédie Française from 1879 until his death. He specialized in supporting comedy parts. (A. M. N.)

**COQUIMBO**, province and city of northern Chile. The province lies between Aconcagua and Atacama provinces and extends from the Pacific to the Argentine frontier. It is within the arid to semiarid region of east-west trending valleys and brush-covered ridges which is known as the Little North (Norte Chico). Area 15,308 sq.mi. Pop. (1960) 309,177. It is one of the eight original Chilean provinces created in 1826; nevertheless, alterations in boundaries and in administrative subdivisions have occurred. Present limits and internal administrative structure date from 1929 and 1939, respectively.

Pastoral activity (goats, sheep, cattle) is widespread, but the economically more important irrigation and dry farming are concentrated primarily in the valleys of the Elqui, Limarí and Choapa. Subtropical fruit, wines, small grains, edible legumes, early vegetables and alfalfa are produced, primarily for the national market. Mining is scattered, but large-scale operations exist near La Serena (q.v.), the provincial capital.

Iron ore (formerly at El Tofo and after 1956 at Romeral), gold and manganese are the most valuable minerals but apatite, silver, and copper and lead are produced also. There is a cement plant near Cerro Juan Soldado. From 1956 most of the iron ore has been shipped abroad or to the steel town of Huachipato, Concepción, through the mechanized loading facilities at Guayacán, although some is embarked at Coquimbo. The large iron-ore operation is foreign controlled; other mining activities and cement production are Chilean owned.

COQUIMBO, main port and second city of the province (pop. [1960] 41,538 mun.), was founded in 1850. Its industry includes fertilizer manufacture and ore concentrating. The roadstead and dock area, among the best sheltered in Chile, is winter haven for the Chilean navy as well as embarkation point for such cargoes as

cement, phosphate fertilizer, agricultural products and various ores and concentrates. Coquimbo and the adjacent La Serena have air, highway and rail communication to the north and south. Branch railways extend into the Choapa and Elqui valleys from the longitudinal line. Among the towns served by the Elqui branch is Vicuña (pop. [1960] 12,106 mun.), birthplace of the poetess Gabriela Mistral (Nobel prize, 1945). Other cities of note are Ovalle (46,553 mun.) and Illapel (21,662 mun.). About 23 mi. S.E. of Coquimbo is the small village of Andacollo famous for the shrine of the Virgen del Rosario de Andacollo, a place of pilgrimage.

(J. T.)

**CORACIIDAE**, members of the roller family, remarkably coloured old world birds belonging to the order Coraciiformes (*q.v.*). See **ROLLER**.

**CORACIIFORMES**, an order of birds comprising several families of doubtful mutual affinities: the Coraciidae (rollers; *q.v.*), Meropidae (bee eaters) and Upupidae (hoopoes; *q.v.*) of the old world; the Phoeniculidae (wood hoopoes) of Africa and Leptosomatidae (cuckoo rollers and ground rollers) of Madagascar; the Bucerotidae (hornbills; *q.v.*) of Africa and southern Asia; the Momotidae (motmots; *q.v.*) of tropical America and Todidae (todies) of the Greater Antilles; and the cosmopolitan Alcedinidae (kingfishers; *q.v.*). In the most recent classifications, the oil-bird, frogmouths and nightjars (*qq.v.*) or goatsuckers are separated as the order Caprimulgiformes, the swifts and hummingbirds (*qq.v.*) as the order Apodiformes (Micropodiformes), the colies (*coly*; *q.v.*) as the order Coliiformes, and the trogons (*q.v.*) as the order Trogoniformes. See **BIRD: Classification** for complete classification of birds.

**CORAL**, the stony skeletal structure built by any of several simple marine plants and animals, such as calcareous algae and the coral polyp. The skeleton of the polyp, for instance, is built by cells on its bottom and sides that extract calcium carbonate from the sea and deposit it as solid limestone at the polyp's bottom and upward from there to form the walls of the tube-shaped shell that encases the polyp. Limestone processes also are projected inward, creating an interior of stone-walled compartments that the body of the polyp occupies. The animal continues to build upward as it grows and only the top of its body appears over the edge of its stone house. Branching colonies of coral are formed by the budding of new polyps from the tops of older ones, each new creature undertaking the building of its own limestone shell. Coral polyps also are reproduced from eggs expelled by a parent and by a vertical division of the creature's body into two distinct polyps. When a polyp dies its skeleton of coral remains. (See **ANTHOZOA: Zoantharia: Order Scleractinia**.)

The famed precious red coral is found in Mediterranean waters and has been used for centuries as an ornamentation. The Gauls decorated their helmets and weapons of war with coral. The Romans not only prized it for its beauty but also attributed magical and medicinal virtues to it. Roman children wore necklets of coral to ward off danger. It was valued greatly in India and the far east also. India frequently provided so large and so lucrative a market for the substance that the supply in Europe was sometimes severely limited.

The richest yields of coral come from the coastal waters of Algeria and Tunisia. Other profitable deposits are found off the coasts of Spain, Provence, Sardinia, Corsica, Sicily, and in the Bay of Naples. Coral is found at depths ranging from 20 to 1,000 ft. The finest quality, however, is generally found at depths of 100 to 160 ft. Coral is attacked by worms and sponges that bore into it and cause discoloration and decay. Precious coral that is sound usually ranges in colour from white through pink to a deep red. Colour in single pieces of coral tends to be uniform and variations in shade are rare.

Coral fishing is chiefly a summer occupation. The best catches are usually made about five miles out to sea, although some coral can be found nearer shore. The fishermen drag for coral with systems of weighted nets. The catch is brought aboard the fishing boat and sorted out. Coral that shows decay or discoloration has only a marginal value and usually is returned to the sea. Pieces of ordinary red coral in varying sizes are in greatest number, but

there are generally some specimens of rare size and beauty. It is estimated that about ten years are required for a coral bed to replenish itself; consequently a bed is fished only once every ten years.

Coral is processed largely by Italian craftsmen who are skilled in the art of cutting, polishing and carving the material. Small pieces of different shapes are perforated and strung on cords as bracelets and necklaces. Beads, some of them carefully faceted, are fashioned, and domed pieces are formed to set in brooches. The skill of the craftsmen is demonstrated best in their expertly carved cameos and small figurines of coral. The coral industry is centred in the Neapolitan area, particularly at Torre del Greco.

A shining, jet-black coral found in the Indian ocean is highly esteemed in India. The name "king's coral" was conferred upon it because the sceptres of kings were made of it. From Japan comes a lovely shell-pink coral with a pearly sheen. Skilful Japanese craftsmen have created a considerable demand for their finely wrought products.

The coral reefs of the tropics provide limestone material that has been found useful in building roads. The great coral reefs are built by coral polyps and calcareous algae called nullipores. The reef is a mass of cemented skeletal material that has been modified by the placing into solution and recrystallization of its original calcareous content. The top of the reef is largely overlaid by shell and coral flotsam carried in by the sea, and few living creatures are present. On the seaward slope of the reef, however, healthy growths of coral polyps and nullipores increase and multiply, and proceed with their limestone building. Road-making material is obtained from the tops and faces of the reefs by dredging. Blasting is sometimes required.

The coral reefs have been the subject of much geophysical research. Efforts have been made to determine their geological age and to account for the particular nature of the coral atolls.

See **CORAL REEF**; see also references under "Coral" in the Index. (E. L. Y.)

**CORAL-BELLS**, a hardy perennial herb (*Heuchera sanguinea*) belonging to the saxifrage family (Saxifragaceae; *q.v.*).

J. MORACE MCFARLAND CO.  
CORAL-BELLS (HEUCHERA SAN-  
GUINEA)

It is exclusively North American ranging from Mexico to the arctic regions. Coral-bells, the best known of the alumroots (*Heuchera* genus), is a compact, bushy plant growing in tufts with flower stems about 18 in. tall. From its ornamental foliage rise graceful spikes covered with pendant flowers about the size of lily-of-the-valley bells, of a bright coral-crimson colour, blooming about the middle of the summer. The sprays of bloom make excellent cut flowers.

Coral-bells are most attractive when planted by themselves among shrubbery. They are effective also when planted in rockery, where they become robust and the foliage completely covers the rocks. They like a warm soil of medium texture, but will grow in almost anything but pure sand and heavy clay, and they prefer

an open or partly shaded situation.

Propagation is by division of the crowns during spring, the divisions being replanted in beds of sandy soil in a warm sheltered position and grown there for a year. (R. T. V. T.; X.)

**CORAL GABLES**, a residential city of Dade county, on the lower east coast of Florida, U.S., adjoining Miami on the southwest. George E. Merrick developed the city from a nucleus of his family's 160 ac. of citrus and farm land and named it in 1925, the year it was incorporated, for the family's gable-roofed "coral" (actually limestone) house. Well-planned from the beginning,

## A CORAL ATOLL IN THE INDIAN OCEAN

*Left:* A reef flat, exposed at low tide, forming a fringe of coral and containing varied marine life along the shore of one of the Keeling Islands

*Below:* West Island, largest atoll in the Keeling Islands, showing typical coral formation enclosing a quiet lagoon. The island is protected from the pounding surf by the outer reef in the foreground

Damselfish among clusters of coral which serve to protect them from larger predators. At top and left are colonies of staghorn (*Acropora*) corals; rounded corals in centre are *Porites*

A collection of deep-sea corals, photographed with ultraviolet light, glowing with fluorescence. Among them are mushroom, brain, rose and soft corals

### FORMATIONS OF CORAL

building is still controlled by a board of supervising architects. Winter residents live chiefly in their own winter homes or in apartments. There are 12.25 sq.mi. of land area and 22.75 sq.mi. of water in the city. Six miles of waterway navigable for small boats provide access to Biscayne bay and outside waters. Recreational facilities include the Venetian pool, five parks, an extensive youth centre and golf courses. Two private and one veterans hospital are in the city. The University of Miami, founded in 1925 in Coral Gables, is made up of seven schools and a graduate school. The Lowe Art gallery, the University of Miami Symphony orchestra and the "Miracle Mile" shopping area win patronage from greater Miami. For comparative population figures see table in FLORIDA: Population. (C. W. TE.)

**CORAL REEF**, a ridge formed in shallow ocean areas by the calcareous skeletons of certain coelenterates, of which coral polyps are the most important. The biology of these marine animals is discussed in ANTHOZOA and COELENTERATA. Coral polyps build a small skeleton around themselves, and also produce new polyps called buds, which remain attached to the parent skeleton, create a new skeleton of their own and form new buds. By repetition of this process a great mass of coral skeletons is produced, and the resultant form is called a coral reef. There are three chief types of reef: (1) the barrier reef, backed by a lagoon in which an island is located; (2) the atoll (*q.v.*), in which the reef, taking the shape of an irregular horseshoe or ring, encloses a lagoon with no island; and (3) the fringing reef, a sea-level flat, built out from the shore of a continent or island.

Corals can live only under fairly restricted conditions. Reef builders cannot live more than 300 ft. beneath the sea surface, and corals proper do not live below 150-ft. depth. Corals cannot endure temperatures lower than 65° F. nor higher than 96°, flourishing best between 77° and 86°. They cannot live out of water. Because they demand such warm water, corals are found mostly within the tropics, their maximum range being from about latitude 30° N. to a slightly higher latitude south. Corals prefer moving water because it brings more food and contains more oxygen. They cannot tolerate very silty water because it will bury them. Corals usually establish themselves by attaching to rocks, but in still water they can live directly on sand. The great area for coral reefs is the central, western and southwestern Pacific, but other extensive coral formations are found in the West Indies, along the coast of Brazil, in the Red sea, the western Indian ocean and Indonesia.

The outer edge of the coral reef pitches downward at a steep angle, sometimes to more than 1,000 ft. depth. In places the reef may overhang, having been built outward by the coral polyps in an effort to reach additional light. Where the surf is great, corals ordinarily cannot live at depths of less than six or eight feet, but certain kinds of algae, which can, add to the substance of the reef at the windward edge. The character of the reef's inner slope, dropping off into the lagoon, varies according to its exposure to waves. It is usually a gentle slope, covered with calcareous sand derived from the reef surface.

The surface of the reef varies from a few hundred feet to a few thousand feet in width. It lies nearly at sea level, and during periods of low tide the higher parts project above the surface of the water. Calcareous sand and blocks are strewn over the surface and caught in the hollows. On large reefs low islands sometimes develop from detritus derived from the reef surface.

The lagoons that lie behind barrier reefs and in the centres of atolls have mostly smooth, sandy bottoms, but some contain numerous (even hundreds) of little hills formed by coral erected from the bottom of the lagoon.

Barrier reefs usually are pierced by several channels which give access to the lagoon and island behind the reef. Around the leeward sides of most islands possessing fringing reefs there are large interruptions of the reef. The most famous of all barrier reefs is the Great Barrier reef of northeastern Australia (see BARRIER REEF), which is more than 1,700 nautical miles in length. Atolls range in size from less than a mile to more than 40 mi. in diameter. The parts of the reef are the same as those of the barrier reef. Chains of small atolls are called faros.

Coral reefs and their associated lagoons are commonly very beautiful and attractive places. The lagoons are generally calm and extremely clear and the water is an extraordinarily attractive and characteristic shade of blue. The inner slope of the reef thus exhibits an abundance of colourful and variegated animal life, and the often colourful coral, while out on the reef itself a giant surf may ceaselessly pound.

The problem of the origin of coral reefs is one of the most difficult in geomorphology. Since the 19th century attempts have been made to account for coral reefs by a single theory of origin, but students have begun to believe that several factors are important and that different reefs have had quite different histories. The first scientific theory to explain coral reefs was developed by Charles Darwin, who asserted that the reefs began to grow around

FROM T. J. STORER AND R. L. USINGER, "GENERAL ZOOLOGY"; REPRODUCED BY PERMISSION OF MCGRAW-HILL CO., INC.

**DARWIN'S THEORY OF FORMATION OF A CORAL REEF:** (A) FRINGING CORAL REEF ENCIRCLES A ROCKY OCEANIC ISLET; (B) BARRIER REEF ENLARGES AS SEA LEVEL RISES (OR LAND SINKS); (C) AS SEA LEVEL CONTINUES TO CHANGE, AN ATOLL, SURROUNDED BY THE CORAL REEF, REPLACES THE ISLET

islands as fringing reefs and that as the island gradually sank beneath the sea the coral grew upward and outward as rapidly as the sea rose. Thus the fringing reef became a barrier reef. As the island sank completely beneath the sea the barrier reef became an atoll. Numerous other theories have been developed, of which the most important is based on known fluctuations in sea level during the glacial periods. Darwin's subsidence theory, however, still explains more facts of coral development more rationally than any other. See also PACIFIC ISLANDS.

**BIBLIOGRAPHY.**—W. M. Davis, *The Coral Reef Problem*, American Geographical Society special publication no. 9 (1928); R. A. Daly, *The Changing World of the Ice Age* (1934); J. Y. Costeau, "Fish Men Explore a New World Undersea," *National Geographic Magazine*, 102:431-472 (1952); André Guilcher, *Coastal and Submarine Morphology*, trans. by B. W. Sparks and R. H. W. Kneese (1958). (W. C. C.)

**CORAL SEA, BATTLE OF THE** (May 7-8, 1942), the first naval engagement in which all losses were inflicted by air action and no ship on either side sighted an enemy vessel. The main objective of the U.S. forces was a Japanese fleet under Adm. Takeo Takagi en route from Rabaul to capture Port Moresby on the island of New Guinea. About noon on May 7, Japanese planes sank the U.S. naval tanker "Neosho" and the escorting destroyer "Sims." Planes from Adm. Frank Jack Fletcher's American carriers, "Yorktown" and "Lexington," sank the small Japanese carrier "Shoho." On the morning of May 8, planes from the "Yorktown" damaged the "Shokaku," another Japanese carrier, with two bomb hits. Both the "Lexington" and the "Yorktown" were hit by Japanese planes and the "Lexington" eventually sank. The Japanese force withdrew and returned to Rabaul. See WORLD WAR II: *The War in the Pacific*.

**CORAM, THOMAS** (1668-1751), English philanthropist who established the London Foundling hospital, was born at Lyme Regis, Dorset. He became a merchant sea captain, trading between England and America, but from about 1693 to 1703 he was a boatbuilder and farmer at Boston and at Taunton (Mass.), and he finally retired to England in 1720. Appalled at the number of infants abandoned in London, he enlisted the help of influential people and after 17 years' work obtained in 1739 a royal charter for a hospital for foundling infants (see FOUNDLING HOSPITAL). He had used all his money on the scheme and an annuity of 160 guineas was raised for him by public subscription. Coram also worked to promote the settlement of Georgia and Nova Scotia. He died in London on March 29, 1751.

See R. H. Nichols and F. A. Wray, *The History of the Foundling Hospital* (1935). (FR. C. B.)

**COR ANGLAIS**, a wood-wind instrument also known as the

**English horn.** It is a large oboe pitched a fifth below the ordinary oboe, from which it also differs in having a bulbous bell, and at the top end a bent metal crook on which the double reed is placed. Its music is written a fifth higher than it sounds. The name first appeared in Vienna, about 1760; "cor" refers to the curved or hornlike shape in which the instrument was then built, but "anglais" remains a mystery (an allusion to the Anglo-Hanoverian bugle horn has been suggested). The curved form survived locally up to 1900, though the modern straight form was first exhibited by Henri Brod of Paris in 1839. The veiled, pastoral tone has been romantically employed in many operas and symphonic works, and the instrument, played by an oboist, is a regular member of the orchestral wood wind and is used also for Bach's *oboe da caccia* parts. See also **OBOE**. (A. C. BA.)

**CORATO**, a town of southeast Italy, province of Bari, region of Puglia, lies on a slope descending to the Adriatic sea 41 km. (25 mi.) W. of Bari by road. Pop. (1957 est.) 43,554 (commune). The ancient centre of the town is surrounded by modern buildings. The chief features are the romanesque church of Sta. Maria Maggiore (13th century), the 14th-century church of S. Domenico, the Palazzo Catalano (15th century) and the Palazzo Ottinera. The main industries are agriculture, including vegetables, and the production of wine and oil. Founded by the Normans, Corato became subject to Alfonso V of Aragon at the end of the 15th century and later to the Carafa. In World War II it was captured by the Allies in Sept. 1943. (M. T. A. N.)

**CORAX** of SYRACUSE (5th century B.C.) is believed to have written the first Greek treatise on rhetoric. There is little reliable information about his life or his work, of which nothing survives. He was active at a time when democratic constitutions had replaced tyrannies in Sicily. He specialized in the theory of forensic oratory and is said to have advocated argument "from probability" and to have prescribed rules for the subdivision of speeches. Corax and his pupil Teisias were proverbially associated by the Greeks and Romans with legal quibbling.

See L. Radermacher, *Artium Scriptores* (1951). (H. L. H.-W.)

**CORBEIL** (CORBAIL, CORBEUIL), **WILLIAM OF** (d. 1136), archbishop of Canterbury, was born probably at Corbeil on the Seine and educated at Laon. He entered the order of St. Augustine, became prior of the Augustinian foundation at St. Osyth in Essex and in 1123 was chosen archbishop of Canterbury, being consecrated only after a long conflict with Thurstan, archbishop of York. After a dispute with the papal legate, Cardinal John of Crema, William himself was appointed legate in England and Scotland, an important precedent in the history of the English church. William built the keep of Rochester castle and finished the cathedral at Canterbury, which he dedicated with great pomp in May 1130. He died at Canterbury on Nov. 21, 1136.

See the article by T. F. Tout in the *Dictionary of National Biography*, where earlier work on the subject is summed up.

**CORBEL**, in architecture, a means of supporting a projecting weight; a bracket or weight-carrying member, built deeply into the wall so that the pressure on its embedded portion counteracts any tendency to overturn or fall outward. Corbels may be either individual pieces of stone, separated from each other like brackets, as in the case of many medieval cornices; or continuous courses of masonry, e.g., the corbels under projecting oriel windows. A corbel table is a projected band or string course carried on corbels. Corbels are favourite places for decoration. Medieval cornices frequently have corbels ornamented with leaves, animals or human heads, and the corbels common in Eng-

lish Gothic, to support vaulting shafts, are rich with leafage. The sides and faces of Renaissance corbels are carved with scrolls and acanthus leaves. In many cases corbels have molding, without other carving, especially those carrying medieval battlements. Corbels decorated with an S-scroll are known as consoles. See also **ARCH** and **VAULT**.

**CORBETT, HARVEY WILEY** (1873-1954), U.S. architect, one of the designers of Rockefeller Center, New York city, and other distinguished modern public buildings, was born in San Francisco, Calif., Jan. 8, 1873. He graduated from the University of California, Berkeley, in 1895 and from the École des Beaux-Arts, Paris, in 1900. As a member of the firm of Corbett and MacMurray he was instrumental in designing the Bush Terminal office building, New York; Bush house, London; and Holy Innocents church, Brooklyn, N.Y.

The firm of Corbett, Harrison and MacMurray collaborated with others in creating the imposing group of skyscrapers of Rockefeller Center. Constructed between 1932-40, the buildings represent the first skyscrapers built as a unified group. Corbett died April 21, 1954, in New York city.

His wife, **GAIL SHERMAN CORBETT** (1873-1952), a sculptor, was born in 1873 in Syracuse, N.Y. Her best-known works are the Hamilton S. White memorial and the Kirkpatrick fountain in Syracuse, N.Y., the bronze entrance doors of the municipal group at Springfield, Mass., and the medallion head of Washington in the pediment of the George Washington National Masonic memorial at Alexandria, Va. She died in New York city Aug. 27, 1952.

**CORBETT, SIR JULIAN STAFFORD** (1854-1922), British naval historian, was born at Imber court, Thames Ditton, Surrey, Nov. 12, 1854. After attending Trinity college, Cambridge, he was called to the bar by the Middle Temple in 1877 and practised law until 1882. He published a number of novels and then became a lecturer on history at the Naval War college. Corbett's fame rests on his naval writings, which include: *Drake and the Tudor Navy* (1898); *The Successors of Drake* (1900); *England in the Mediterranean, 1603-1714* (1904); *England in the Seven Years' War* (1907); *The Campaign of Trafalgar* (1910); *Some Principles of Maritime Strategy* (1911); and *The Official History of the Great War Naval Operations* (1920-23). He was knighted in 1917 and died Sept. 21, 1922. (J. B. HN.)

**CORBETT, RICHARD** (1582-1635), bishop of Oxford and Norwich, and one of the most fashionable minor Caroline poets. Born at Ewell, Surrey, in 1582, he was educated at Westminster school, Broadgates hall (later Pembroke college) and Christ Church, Oxford, with which college many of his poems are connected. In the controversy with the Puritan party in the university, Corbett supported the Arminians, under Laud, but he owed his advancement to friends like Sir Thomas Aylesbury, a patron of learning and secretary to the duke of Buckingham. In 1620 he became dean of Christ Church; his marriage to the daughter of a canon of the cathedral brought him a son, Vincent (to whom he addressed one of his happiest poems) and a daughter. Flattering verses written to Buckingham helped to procure him (in 1628) the bishopric of Oxford, whence Laud translated him (1632) to Norwich, a larger though hardly more lucrative see. Corbett constantly satirized the Puritans, but he did little to repress their activities in East Anglia. He died in Norwich, July 28, 1635. His memory survives partly because of several good stories told of him by John Aubrey, but more because of his felicitous "Faeries Farewell," from the first line of which Rudyard Kipling took the title *Rewards and Fairies*. Most of his other verses (including the long "Iter Boreale," in heroic couplets) were occasional, and no edition appeared till 1647; the value of this and later collections is discussed by J. A. W. Bennett and H. R. Trevor-Roper in their edition (1955), which includes a biography, notes and a list of manuscript sources.

See also O. Gilchrist's edition (1807), the only one between the 17th century and the 20th, a valuable work including a *Life*. (J. A. W. B.)

**CORBIÈRE, TRISTAN** (real name ÉDOUARD JOACHIM CORBIÈRE) (1845-1875), an important and original French poet, was born, July 18, 1845, at Coat-Congar, near Morlaix, Brittany. Educated at Morlaix and the lycées of Saint-Brieuc and Nantes

FROM F. S. MEYER, "HANDBOOK OF ORNAMENT"

SIDE VIEW OF CONSOLE FROM THE VATICAN, ROME

he settled in Roscoff where, apart from three years in Paris, he spent the rest of his life and wrote most of his only volume of poems, *Les Amours jaunes* (1873). The main themes are love, Paris, the sea and, above all, Brittany. But Corbière is more than the poet of Brittany and his realistic pictures of sea-faring life and the pilgrims at the *pardon* of Ste. Anne transcend the region that inspired them. He is original in his use of irony and of a familiar, spoken kind of poetry in opposition to the elevated lyricism of the Romantics whom he frequently parodied. His work has affinities with that of Charles Baudelaire, but he did not belong to any literary school and was almost unknown until Paul Verlaine included him in *Les Poètes maudits* (1884). His importance as an innovator and his greatness as a poet are generally recognized, as is also the influence he exercised on several French writers (notably Jules Laforgue; *q.v.*), on the development of French poetry and on the early works of Ezra Pound and T. S. Eliot. He died at Morlaix, March 1, 1875.

Sonnenfeld, *L'Oeuvre poétique de Tristan Corbière* (1960); C. F. Macintyre, *Tristan Corbière* (selections in Eng. trans., 1954.) (C. A. HA.)

**CORBRIDGE**, a town of Northumberland, Eng., is 17 mi. W. of Newcastle by road, on the north bank of the Tyne, there crossed by a seven-arched bridge of 1674. Pop. (1951) 2,434. The Roman station of Corstopitum lay  $\frac{1}{2}$  mi. W. on the line of Dere Street and was the principal Roman military and civilian settlement behind Hadrian's wall. It was abandoned in the 5th century, but by about 760 nearby Corbridge was again an important town in the Northumbrian kingdom, and its church dates partly from this period. It was the scene of a battle in 914, was occupied by David of Scotland in 1138, and ravaged by Wallace in 1296, by Bruce in 1312 and by David II in 1346. It has two peel towers, one the vicar's house, and many harmonious 18th- and 19th-century houses and market place. The Roman excavations and museum are open to the public. (M. G. C.)

**CORBULO, GNAEUS DOMITIUS** (d. A.D. 67), Roman general, gained successes on the Rhine in A.D. 47 over the German tribe of the Frisii and a reputation which led to his appointment by the emperor Nero as legate of Cappadocia and Galatia in 54 to recover Armenia, then occupied by Tiridates, brother of the Parthian king, Vologaeses (*q.v.*). At first Corbulo seems to have proposed that Tiridates should hold Armenia as a Roman vassal; only when this was rejected, did he invade Armenia (58-60), and install a Roman nominee, Tigranes, on the throne. Corbulo then retired to his province of Syria. But Tigranes provoked a new Parthian attack (61), and as he was unable to maintain himself without Roman aid, and Vologaeses still refused the proffered compromise, Nero sent out L. Caesennius Paetus, ostensibly to conquer Armenia from Cappadocia, while Corbulo defended Syria. Paetus, however, was forced to surrender at Rhandaia (62) and Corbulo once more had to enter Armenia with a larger army to restore Roman prestige. Vologaeses at last recognized that he could not secure Armenia for Tiridates by force (63) and after prolonged negotiations Tiridates went to Rome and did homage to Nero (66). Corbulo remained in Syria till 67, when his son-in-law Annus Vinicianus conspired against Nero. Corbulo was recalled and had to commit suicide. His exceptionally long tenure of command shows that he had till then enjoyed Nero's confidence; despite some modern theories, he must have been the trusted executant, if not the prompter, of Nero's Armenian policy.

See Tacitus, *Annals*, xii-xv *passim*; J. G. C. Anderson in *Cambridge Ancient History*, vol. x, ch. 22 and bibliography (1934). (P. A. BR.)

**CORBY**, a town and urban district of Northamptonshire, Eng., lies 22 mi. N.E. of Northampton by road. Designated as one of the New Towns (*q.v.*) in 1950, Corby grew from a village of 1,596 people (1931 census) to a community of 36,322 in 1961. The anticipated population is 70,000. The town centre, opened in 1954, is built on an "H" pattern comprising the three main streets, the market square and bus station and enclosed by the police station, courthouse, civic centre, technical college and library. The civic centre gives access to a public open space

of about 225 ac. Corby stands at the centre of an iron ore bed stretching from Lincolnshire to Oxfordshire, and the surrounding areas of woodland were originally part of Rockingham forest. The church of St. John the Baptist dates from the 13th century. The chief industry is the manufacture of steel tubes, the Corby works being one of the largest in Europe. (G. B. BL.)

**CORDAY, CHARLOTTE** (1768-1793), the assassin of the French revolutionary Jean Paul Marat (*q.v.*), was born at St. Saturnin, near Séez, in Normandy on July 27, 1768, of the noble family of Corday d'Armans. Educated in a convent at Caen and royalist by sentiment, with an easily excitable imagination, she is said to have derived ideas of grandeur and heroism from the literature of the Enlightenment. When the Girondins were being overthrown in the Convention in Paris (May-June 1793), she was living with an aunt in Caen. Caen then became the centre of a "federalist" movement in the Norman *départements* against the Convention, and the Girondin refugees J. Pétion de Villeneuve, François Buzot and Charles Barbaroux arrived to urge military action against Paris. Inspired especially by Barbaroux, Charlotte Corday decided to devote herself to the Girondin cause and set off for Paris. There she saw how Marat's newspaper was exercising a predominant influence on the masses. After writing to solicit an interview with Marat on the pretext of wanting to tell him of events in Caen, she went to his house and finally got herself admitted to his presence while he was in his bath. When she named persons connected with the dissidence in Normandy, he noted them and assured her that they would be guillotined in a few days. She then drew a knife from under her dress and stabbed him through the heart. This was on July 13, the very day on which the insurgent Normans marching on Paris were defeated by a column of Parisian *sans-culottes* at Pacy-sur-Eure. Arrested on the spot, Charlotte Corday was sentenced to death by the Revolutionary tribunal and executed on July 17, 1793. Her act of assassination had a very different effect from what she had expected: it prompted the Convention and the people of Paris to take effective measures against counter-revolution. These saved the republic.

See C. Vatel, *Charlotte Corday et les Girondins*, 3 vol. (1864-72). (A. So.)

**CORDELIERS, CLUB OF THE** (SOCIETY OF THE FRIENDS OF THE RIGHTS OF MAN AND OF THE CITIZEN), one of the popular clubs of the French Revolution. It was founded in the Paris district of the Cordeliers and at first held its meetings in the nationalized monastery of the Cordeliers (Franciscans of the strict observance). Its main aim, as quoted by the *Moniteur* of May 5, 1790, shortly after the club's foundation, was "to denounce to the tribunal of public opinion abuses of the various powers and all infractions of the rights of man."

In 1791, under the leadership of such men as Marat and Danton, the Cordeliers became a political force. Having denounced (April 17) Louis XVI's collusion with the resistance to the Civil Constitution of the Clergy and the support that this collusion was receiving from the mayor of Paris, J. S. Bailly, and inspired the demonstration (April 18) against the king's proposal to leave Paris for St. Cloud, the club was expelled from the convent on May 12. It then reassembled at the Salle du Musée in the rue de Thionville (now rue Dauphine). After the king's flight to Varennes (June), the club demanded his deposition and, to present their petition, organized the famous demonstration in the Champ-de-Mars (July 17), which was dispersed by the national guard, 50 demonstrators being killed. Some of the Cordeliers, including A. F. Momoro, editor of the club's *Journal*, were then arrested, others went into hiding, but the club was meeting again by August.

After the fall of the monarchy (Aug. 1792) Danton and his friends seem to have neglected the club, leaving such men as Momoro, F. R. Vincent, C. P. H. Ronsin and, most important, J. R. Hébert (*q.v.*) in control of it. In 1793 the Cordeliers took a preponderant part in the overthrow of the Girondins. Thenceforward they were the extremists of the popular movement, favouring autonomy for the local sections, direct democracy, the formation of the "revolutionary army" to terrorize Paris, and

the atheistic program of the Paris Commune. Conflict with the government ensued. When Vincent and Ronsin were arrested (Jan. 11, 1794) under pressure from the moderates, the Cordeliers reacted violently, expelled their own moderate members (including Camille Desmoulins) and secured the prisoners' release (Feb. 2). Then, on March 4, they attempted to seize power by insurrection. This failed. Hébert and his friends were arrested and, on March 24, executed.

The leaderless remnant of the club tried a *rapprochement* with the Jacobins but fell into stagnation and oblivion. By the end of 1794 nothing more was heard of it.

Mathiez, *Le Club des Cordeliers pendant la crise de Varennes et le massacre du Champ de Mars* (1910; supplement, 1913). For a list of the publications of the Cordeliers see M. Tournoux, *Bibliographie de Paris pendant la Révolution*, vol. ii (1894), no. 9795-9834. (A. So.)

**CORDIERITE**, a silicate of magnesia, ferrous oxide, and alumina, is a rock forming mineral named in 1813 by R. J. Haüy in honour of P. L. Cordier who discovered its remarkable pleochroism, or exhibition of different colours when viewed from different directions.

The natural mineral, sometimes known as iolite, has little or no commercial use, principally due to the large amount of ferrous iron in the crystals. Synthetic magnesian cordierite has a low thermal expansion and is valuable as a semirefractory thermal shock resistant ceramic material.

Cordierite occurs in igneous rocks only as a result of contamination of the magma by aluminous sediment. As such it is known in granites, norites, rhyolites, andesites and lamprophyres. The true home of cordierite is in the thermally altered argillaceous or clayey sediments surrounding igneous intrusions and in the paragneisses (see GNEISS) and schists. In the former it is the commonest constituent of the spots of spotted slates. In the hornfelses it is frequently associated with andalusite, sillimanite, spinel and corundum. Pre-Cambrian deposits of the Laramie range, Albany county, Wyo., contain more than 500,000 short tons of cordierite analyzing 8%-11% FeO, 6%-7% MgO, about 2% CaO, 28%-30% Al<sub>2</sub>O<sub>3</sub> and 50%-52% SiO<sub>2</sub>.

Fine, well-developed crystals of cordierite are rare. It crystallizes in the orthorhombic system, well developed crystals being usually short prisms with large basal planes. In rocks cyclic twins are common, giving crystals a pseudo-hexagonal habit. A. Miyashiro, T. Iiyama and their colleagues have claimed that at least two pseudo-hexagonal forms of cordierite occur in nature and that these forms differ from the more pure, practically iron-free synthetic compounds which have been called  $\alpha$ ,  $\beta$  and  $\mu$ -cordierite. They suggest that the synthetic forms be called  $\alpha$ ,  $\beta$  and  $\mu$ -indialite and that cordierite be reserved for the naturally occurring types.

In refraction, density and hardness, natural cordierite resembles quartz (*q.v.*), but it can be distinguished by its optical character when viewed under the petrographic microscope.

The formula of cordierite is 2(Mg,Fe)O.2Al<sub>2</sub>O<sub>3</sub>.5SiO<sub>2</sub>. Pure magnesian cordierite can be prepared artificially, a low temperature  $\beta$  form by hydrothermal methods (by H. S. Yoder at 490° C. and 5,000 lb. per square inch), a high temperature  $\alpha$  form by reacting MgO, Al<sub>2</sub>O<sub>3</sub> and SiO<sub>2</sub> above 1,300° C., and a metastable  $\mu$  form by crystallizing the finely powdered glass at 850° C. for 15 days. The  $\beta$  and  $\mu$  forms revert easily to the  $\alpha$  form when heated to 1,000° C. Synthetic cordierite will take silica into solid solution, forming a range of compositions from 2MgO.2Al<sub>2</sub>O<sub>3</sub>.5SiO<sub>2</sub> to MgO.Al<sub>2</sub>O<sub>3</sub>.4SiO<sub>2</sub>. The 2:2:5 composition melts incongruently to mullite (3Al<sub>2</sub>O<sub>3</sub>.2SiO<sub>2</sub>) and glass at 1,470° C. and it will completely melt at 1,530° C. (F. A. HL.)

**CORDILLERA**, a Spanish term for a range or chain of mountains, derived from the Old Spanish *cordilla*, the diminutive of *cuerda*, a cord or rope. The name first given to certain mountain ranges of South America, Las Cordilleras de los Andes, was applied to the extension of the system into Mexico. In North America the Rocky mountains, the Sierra Nevada and the mountains between them are collectively known as the Cordilleras, and the entire area has been termed the Cordilleran region. The name is not restricted to the Americas but is often used as a ge-

neric term for any long parallel ranges of mountains.

**CORDILLERA, LA**, a department of central Paraguay (area 1,910 sq.mi.; pop. [1960 est.] 184,415), was previously named Caraguatay. Its present name is derived from Cordillera de los Altos, the spur of the Brazilian plateau which reaches the Paraguay river bounding the department on the west. The principal road of Paraguay, the Mariscal Estigarribia highway, penetrates this hilly country where the capital, Caacupé, is situated. Piribebuy, the scene of a critical battle (Aug. 12, 1869) in the War of the Triple Alliance and a centre of a fertile agricultural district producing sugar, oranges, tobacco and cattle, is also in La Cordillera. San Bernardino on Lake Ypacaraí is Paraguay's most famous tourist resort. (G. J. B.)

**CORDITE**, a British propellant of the double-base type, so called because of its customary but not universal cordlike shape. Double-base propellants generally contain nitrocellulose (guncotton), a liquid organic nitrate (e.g., nitroglycerin) having the property of gelatinizing nitrocellulose, and a stabilizer. The amounts of these ingredients may vary but generally have contained 30% to 40% nitroglycerin and 5% petroleum jelly as a stabilizing agent. Cordite is soluble in acetone, which is used in colloidizing the mixture. The original cordite (Cordite Mark I), as manufactured at the royal gunpowder factory, Waltham Abbey, Eng., in 1890, was composed of 37 parts of guncotton, 57.5 parts of nitroglycerin and 5 parts of mineral jelly together with 0.5% of acetone. Because of its large content of nitroglycerin this cordite had a high temperature of explosion and produced considerable erosion of big guns. A modified composition, Cordite M.D., which was introduced in 1901, contained 64 parts of guncotton, 30.2 parts of nitroglycerin and 5 parts of petrolatum with about 0.8% of acetone. Cordite M.D. proved to be a very stable composition with long storage life. The nitrocellulose had a nitrogen content of 13.1%. Modified cordite compositions containing other organic nitrates, replacing the nitroglycerin, were introduced during World War II. Such nitrates include dinitrotoluene, nitronaphthalene, nitroguanidine and diethylene glycol dinitrate (DEGN). The use of these nitrates significantly lowered the burning temperature, which resulted in reduced gun erosion, permitting the firing of many more rounds from a gun barrel. See EXPLOSIVES; PROPELLANTS. (P. M. FE.)

**CÓRDOBA**, a central province of Argentina. Pop. (1960) 1,759,997; area 65,161 sq.mi. The western margins of the province contain the famous mountains, Sierras de Córdoba, which rise to an altitude of 9,462 ft. above sea level. The land slopes eastward to the great pampa, being drained by the five rivers rising in the sierras (Primero, Segundo, Tercero, Cuarto and Quinto). Only the Tercero reaches the Paraná; the others terminate in swamps or in the saline Mar Chiquita in northeast Córdoba.

Winters are mild and summers hot in Córdoba. Most rain falls between November and February. Except in their highest parts the sierras are forested, but the plains form part of the great pampa grassland. The wooded valleys and contrasting relief of the hills make the sierras a favourite holiday centre.

The principal settlements in Córdoba were founded in the 16th century, when trade was carried on with Bolivia and Chile. Cattle and mules were bred on the plains and in the irrigated valleys for the farms of the province of Salta. Córdoba was a stubborn centre of Spanish resistance in the war of independence but joined the republic in 1816. In 1852-62 it strongly supported the Argentine confederation against the dominance of Buenos Aires. The completion of the railway from Rosario in 1869 was the first important link with the east, but Córdoba remained a centre of provincial loyalties and played a significant part in the overthrow of Pres. Juan Perón in 1955.

Córdoba shared the general economic expansion resulting from the increased investment and immigration of the late 19th and early 20th centuries, which transformed the Argentine pampa. More than 15,000,000 ac. are devoted to the production of wheat, maize, flax, alfalfa, oats and barley. Stock-raising is of great importance; granite and limestone are quarried; and wolfram, mica and beryllium are mined in the sierras. The chief industria-

centres, which process foods and manufacture textiles, are the capital Córdoba, Río Cuarto (q.v.) and Villa María. Alta Gracia, Cosquín, La Cumbre, Capilla del Monte and La Falda are important tourist resorts in the sierras. A network of 3,000 mi. of roads, 3,000 mi. of railways and national and international airlines provide the province with excellent communications.

(G. J. B.)

**CÓRDOBA**, a department of northern Colombia facing the Caribbean sea. Area 9,720 sq.mi.; pop. (1964) 585,714. Córdoba was created out of the southwest portion of the department of Bolívar in 1951. It is one of the most important cattle-raising areas of Colombia, annually exporting thousands of head to interior and export markets. Cotton, rice and maize have been cultivated on extensive holdings along the Sinú river. The capital and chief town is Montería (pop. [1964] 70,531). It is connected with Medellín and Cartagena by daily air service and by river boat with Cartagena and the lower Sinú ports of Cereté and Loricá. During most of the colonial period the area was sparsely settled, the original dense Indian population, evidenced by archaeological remains, having disappeared by the time of the first major Spanish *entrada* in 1534. A large proportion of the settlers, especially in the area above Montería, come from Antioquia. See COLOMBIA.

(Js. J. P.)

**CÓRDOBA**, the third city of Argentina, capital of the central province of the same name, lies on the Río Primero, 432 mi. by rail northwest of Buenos Aires via Rosario. Pop. (1960) 589,153. The city stands on a high plain called the *altos*, 1,440 ft. above sea level, the older part being south and west of the river. Founded in 1573 by Jerónimo Luis de Cabrera, Córdoba was long the regional headquarters of the Jesuits and for a time capital of the Spanish *intendencia* of Tucumán. The Jesuit foundation of the university in 1613 made Córdoba the cultural metropolis of southern South America. It played an important part in the struggle between Buenos Aires and the provinces. Pres. Domingo Sarmiento (q.v.) completed the railway from Rosario to Córdoba, thus linking the city to the developing economy of the pampas. Córdoba remained the traditional centre of conservatism but after 1912 its control by the Radicals reflected the growth of the industrial population. In 1955 Gen. Eduardo Lonardi's capture of Córdoba initiated the downfall of Pres. Juan Perón.

Córdoba's rich colonial inheritance is displayed by the old *cabildo* (town council chambers), the cathedral, the viceroy's palace, and the Jesuit churches grouped near the core of the old city. The Plaza San Martín commemorates the liberator of Argentina.

The new town is built on a rectilinear plan. Colleges of mining and agriculture, the republic's premier astronomical observatory and numerous industrial plants indicate its regional importance. The Dique San Roque on the Río Primero is one of the largest dams in South America. It supplies Córdoba with water and makes possible the irrigation of orchards and grain fields. The dam also is the source of hydroelectric power for the city's leather, textile, glass and food-processing factories.

Córdoba is the railroad and highway hub of central Argentina, providing the principal links between the pampas and the important centres of the northwest. It has an airport, Pajas Blancas.

(G. J. B.)

**CÓRDOBA** (CÓRDOVA), capital of the southern Spanish province of the same name, lies on the southern slopes of the Sierra de Córdoba and the right bank of the Guadalquivir river (ancient Baetis), 132 km. (82 mi.) N.E. of Seville by rail. Pop. (1960) 198,148 (mun.). Córdoba is an episcopal see. It is a typically Moorish city with narrow winding streets, especially in the older quarter of the centre and west. Apart from several ruined towers and gates, few fragments remain of the ancient walls which once surrounded it, except in the southwest where they show traces of Roman foundations, and in the northeast. The hills behind the city are planted with olive and orange groves and there are gardens beyond the walls on the west. A Moorish bridge with 16 arches on Roman bases connects Córdoba with its suburb across the river. At the southern end of the bridge stands the

tower of La Calahorra; at the north a ruined gateway and near by an elevated statue of the city's patron, Archangel Raphael. West of the bridge, near the river, lies the Alcázar or palace quarter, probably the original nucleus of the town. Here stood the Roman civil and military buildings which the Arab caliphs converted into a royal residence. The site of the Old Alcázar, where the royal guards were quartered, was gradually built over by workmen's houses. The New Alcázar, which was the palace itself and later the residence of the Holy Inquisition, is now mainly in ruins, except one wing, which is used as a prison. Gardens overlooking the river, the bishop's palace and an ecclesiastical seminary also occupy part of the site. Other important public buildings are the old monastic establishments, the churches (notably S. Hipólito and S. Nicolás de la Villa), the city hall, the hospitals, the schools and colleges (including the academy for girls, founded in 1590 by Bishop Pacheco of Córdoba, which is empowered to grant degrees), a music conservatory, and museums of fine arts and archaeology.

But the glory of Córdoba, surpassing all its other Moorish or Christian buildings, is the *mezquita*, or mosque, now a cathedral (consecrated in 1236 to honour the Assumption of Mary), but originally founded on the site of a Roman temple and a Visigothic church by Abd-al-Rahman I, who wished to make his capital a great religious centre, rivaling those of the east. The growing population of the city soon rendered a larger mosque necessary and, by orders of Abd-al-Rahman II and al-Hakam II, the original size was doubled. After various minor additions, al-Mansur, the vizier of the caliph Hisham II, again enlarged the Zeca, or House of Purification, as the mosque was named, to twice its former size, rendering it the largest sacred building of Islam, after the Kaaba at Mecca. The ground plan of the completed mosque forms a rectangle, measuring 590 ft. by 425 ft., or little less than St. Peter's in Rome. About one-third of this area is occupied by the famous Patio de los Naranjos (Court of the Oranges) and the cloisters which surround it on the north, west and east. Passing through the courtyard, the visitor enters on the south a labyrinth of pillars in which porphyry, jasper and many-coloured marbles are boldly combined. Part came from the spoils of Nîmes or Narbonne, part from Seville or Tarragona, some from the older ruins of Carthage and others as a present to Abd-al-Rahman I from the Byzantine emperor Leo IV, who sent also from Constantinople his own skilled workmen, with 16 tons of tesserae for the mosaics. Originally of different heights, the pillars have been adjusted to their present standard of 13 ft. either by being sunk into the soil or by the addition of Corinthian capitals. The present 850 pillars divide the building into 19 north-to-south and 29 east-to-west aisles, each row supporting a tier of open Moorish arches of the same height (12 ft.), with a third and similar tier superimposed upon the second. The Moorish character of the building was unfortunately impaired in the 16th century by the erection in the interior of a *crucero*, or high altar and large cruciform choir, by the formation of numerous chapels along the sides of the vast quadrangle and by the addition of a belfry 300 ft. high in place of the old minaret. The removal of modern vaulting has revealed a wooden Moorish ceiling carved and painted and still practically intact. The most exquisite work in the whole mosque is found in the third *mihrab*, or prayer niche, a small octagonal recess roofed with a single block of white marble, carved in the form of a shell and with its walls inlaid with Byzantine mosaics.

Córdoba was celebrated in Moorish times for its silversmiths, its silk embroideries and for a peculiar kind of leather which took its name from the city, whence is derived the word "cordwainer." Fine gold and sil-

BELL TOWER OF THE CÓRDOBA CATHEDRAL, 1593. THE CATHEDRAL WAS BEGUN IN ABOUT 795

ver filigree ornaments are still produced but the leather industry has degenerated into an imitation of Moorish work. The chief modern industries of Córdoba are brewing and distilling and the manufacture of textiles. Besides some copper from neighbouring mines, the main trade is in filigree work and oil and rough clothing for sale in the Andalusian fairs. Tourist traffic forms an important source of wealth to the inhabitants.

**History.**—Corduba, probably of Carthaginian origin, was occupied by the Romans under Marcus Marcellus in 152 B.C., and shortly afterward became the first Roman *colonia* in Spain, later with the title of *Patricia*. After the battle of Munda in 45 B.C. the city was severely punished by Julius Caesar, and 20,000 of its inhabitants were massacred for having supported the sons of Pompey. Under Augustus, if not before, it became a municipality, and capital of the province of Baetica. Strabo (c. 63 B.C.—c. A.D. 21) testifies to its importance at this period. Its prosperity was due partly to its position on the Baetis, then navigable up to the city, and on the Via Augusta, the great commercial road from northern Spain built by Augustus, and partly to its proximity to mines and rich grazing and grain-producing districts. Under the rule of the Visigoths from the 6th century to the beginning of the 8th century its importance declined but, captured and largely destroyed by the Moors in 711, it entered 50 years later on its period of greatest prosperity. In 756 Abd-al-Rahman I made it the capital of Moorish Spain. Under the Omayyad dynasty the city was reconstructed and filled with palaces and mosques and the walls extended so that the enclosed area was doubled. It reached the summit of its splendour in the middle of the 10th century, under Abd-al-Rahman III (see CÓRDOBA, CALIPHATE OF). A period of decadence began in 1010 owing to rivalry for the caliphate, and in 1236 Córdoba was easily captured by Ferdinand III of Castile. The substitution of Spanish for Moorish supremacy rather accelerated than arrested the decline of art, industry and population; and in the 19th century Córdoba never completely recovered from the disaster of 1808, when it was stormed and sacked by the French. It was captured by Gen. Francisco Franco Bahamonde's nationalist troops early in the civil war of 1936–39.

The city is noted as the birthplace of the rhetorician Marcus Annaeus Seneca, and his more famous son Lucius (c. 4 B.C.—A.D. 65); of the poet Lucan (A.D. 39–65); of the philosophers Averroës (1126–98) and Maimonides (1135–1204); of the Spanish men of letters, Juan de Mena (1411–56) and Luis de Góngora y Argote (1561–1627); and of the painters Pablo de Céspedes (1538–1608) and Juan de Valdés Leal (1630–91). The celebrated captain Gonzalo Fernández de Córdoba (q.v.), the conqueror of Naples, was born in the nearby town of Montilla.

CÓRDOBA PROVINCE forms part of Andalusia (q.v.). Pop. (1960) 798,437. Area 5,296 sq.mi. The Guadalquivir river, flowing through the province from east-northeast to west-southwest, divides it into two very dissimilar portions. North of the river lies the Sierra Morena, a sparsely populated mountainous area which provides winter pastures for the Castilian sheep flocks. Coal mining is carried on at Peñarroya-Pueblonuevo, and silver-lead and zinc are also mined. South of the narrow Guadalquivir valley lie the fertile plains known as La Campiña, rising in the southeast through undulating country to the borders of the Sierra Nevada. These plains are adapted to the cultivation of cereals and provide grazing land for bulls and horses. There are fine vineyards and olive groves, and salt is mined at Rute. This region is the basis of the present wealth of the province and has a density of population twice that of the Sierra Morena. The climate exhibits great contrasts. Snow may lie for months on the mountain peaks while temperatures are mild in the plains, except in the few torrid summer months, when rain seldom falls. Apart from the provincial capital, the most important towns (pop. 1960) are: Puente-Genil (30,185), Lucena (28,287), Priego de Córdoba (25,168), Montilla (23,896), Cabra (20,739), Palma del Río (15,757) and Rute (13,106). The main Madrid-Lináres-Seville railway line follows the Guadalquivir valley and at Córdoba meets the north-south line from Almorchón to Málaga.

**CÓRDOBA, CALIPHATE OF**, the Muslim state that existed in Spain from Jan. 16, 929, when Abd-al-Rahman III assumed the supreme title of caliph, to 1031, when the puppet ruler Hisham III was deposed by his viziers and the caliphate disintegrated into the so-called kingdoms of the Taifa. During this century there were 12 caliphs, all except the first two of whom were puppets and most of whom died by violence.

Abd-al-Rahman III (q.v.) was followed by the studious al-Hakam II (961–976), who gathered a library of 400,000 catalogued volumes, founded 27 free schools in Córdoba and attracted scholars from the east to teach in the university. His reign was succeeded by the dictatorship of al-Mansur (Mohammed ibn abi-'Amir), a professional letter writer who achieved power through the favour of the Basque-born Sultanah Subh ("Dawn") during the minority of her son Hisham II. Al-Mansur's rule (981–1002) marked a period of brilliant military successes abroad and increasing unrest at home. With his mercenary army he won a series of spectacular but ephemeral victories against the Christians, capturing Zamora (981), Barcelona (985), Coimbra (987) and Santiago de Compostela (997), the shrine of the Moor-killing saint. Thence he returned with the cathedral bells to serve as braziers in the famous mosque of Córdoba. (See also MANSUR AL-) Popular opposition to al-Mansur's successors degenerated into partisan warfare between the Cordobans, the Berbers and the slave officials of the royal household, sometimes with Castilian intervention, all sides using the caliphs as pawns in the competition for control of the state. The last caliph was imprisoned with his family in a vault attached to the great mosque and reacted to the news of his deposition by begging for a crust of bread.

The collapse of the caliphate shortly after attaining its military zenith was due partly to the weakening of Omayyad authority by al-Mansur's dictatorship, but mostly to continuous hostilities among Arabs, Berbers, the slave officials, the Jews, the native Spanish converts to Islam (*muladtes*) and the Arabized Christians (*mozárabes*). Under the caliphate Muslim Spain was the most populous and prosperous country of Europe. Increased irrigation produced an agricultural surplus which, with manufactured luxury goods (Cordoban leather, Valencian pottery, "damask" arms and silk from Toledo), was exported mainly eastward.

For the literary and artistic achievements of the caliphate, see ANDALUSIA. See also SPAIN: History; CÓRDOBA.

See R. Altamira, *A History of Spain*, Eng. trans. by M. Lee (1950). (K. Ga.)

**CORDOVA**, a town of south central Alaska, U.S., is situated on the east shore of Orca inlet, a branch of Prince William sound, about 1,500 mi. N.W. of Seattle and 150 mi. E.S.E. of Anchorage. The supply and distribution point for a number of fishing and fur farming localities of Prince William sound. The docks and other fishery and cannery shore facilities suffered damage in the severe earthquake that struck Alaska on Good Friday, March 27, 1964.

Cordova was founded (1908) as a port for the Copper River and Northwestern railroad, which ran to the Kennecott Copper company's mines, 196 mi. away. These famous mines, four in number, reached a depth of about 2,500 ft., with more than 40 mi. of underground workings, and in the 30 years of their operation produced \$200,000,000 worth of copper from ore assaying a 70% metal. After the closing of the mines and the railroad in 1938, Cordova became dependent on its fisheries and salmon, crab and clam canneries. The population is about 1,000. (J. E. Cl.)

**CORDUROY**, a strong filling-pile fabric known for its excellent wearing qualities. The material has a rounded cord, rib or wale surface, with cut pile yarn providing the effect in the vertical direction. The back of the goods has a plain (tabby) or a twill (Genoa) weave. Corduroy is in the family of pile cloths that includes velvet and velveteen. It is made from any of the

major textile fibres and with one warp and two fillings. After corduroy is woven, the back of the cloth is coated with glue; the floats of pile yarn are then cut in their centre. The glue prevents the filling from drawing out of the goods during the cutting. The glue then is removed from the face of the goods, which are subjected to a series of brushings, waxings and singeing to produce a velvetlike ribbed finish. Corduroy is used for breeches, coatings, hunting apparel, millinery, slacks, jackets and trouserings. Its name is believed derived from the French *corde du roi*, "king's cord." (G. E. L.)

**CORELLI, ARCANGELO** (1653–1713), one of the leading violinist-composers of his day, was born at Fusignano, near Imola, Italy, Feb. 17, 1653, and studied principally at Bologna, then a centre of instrumental music. By 1675 he had settled in Rome, which remained his home for the rest of his life. He won a great reputation in society as a performer and composer, as a result of which he made extended visits to other Italian cities and, possibly, abroad. His music was published not only in Italy but also abroad, and he attracted several pupils who later became eminent, among them Francesco Geminiani. He died in Rome, Jan. 8, 1713.

His published chamber works consist of five sets of 12 sonatas; two of *sonate da chiesa* and two of *sonate da camera*, all for two violins, violoncello and continuo (respectively for organ and harpsichord), and one of solo violin sonatas with harpsichord continuo (see CHAMBER MUSIC). He also wrote a set of *concerti grossi*. Corelli seems not to have been on the whole a virtuoso violinist—the technical demands of his surviving violin music never go beyond the third position—but rather one who cultivated a pure, graceful, yet lively style. His slow movements are on the whole his finest, his fast movements tending to become somewhat mechanical. He used only the simplest harmonies within the then-new tonal system.

See M. Pincherle, *Corelli* (1933).

(N. Fo.)

**CORELLI, MARIE** (pseudonym of MARY MACKAY) (1855–1924), English writer who achieved great popularity by her melodramatic expression of Victorian moral fervour, was born in London in 1855. Her pseudonym was chosen for her early career as a pianist and singer. Her fame as a popular writer came with *Barabbas: A Dream of the World's Tragedy* (1893) in which her treatment of the Crucifixion was designed to appeal to popular taste. *The Sorrows of Satan* (1895), also based on a melodramatic treatment of a religious theme, had an even wider vogue, and the climax of her career was reached with *The Murder of Delicia* (1896). Thereafter she was frequently attacked by the more critical public for her sentimentality and poor taste. She had, however, amassed a fortune and in 1901 settled in Stratford-upon-Avon, where she staunchly opposed attempts at its modernization. She died there on April 21, 1924.

See B. Vyver, *Memoirs of Marie Corelli* (1930); E. Bigland, *Marie Corelli* (1953).

**COREOPSIS**, a genus of the Compositae (*q.v.*) family, commonly known as tickseed, containing more than 100 species native almost wholly to America, with a number cultivated in gardens for their showy summer and autumn flowers. They are annual or perennial herbs, seldom shrubs, with conspicuous yellow, rose, purplish-red or purplish-brown flower heads. (J. M. BL.)

**CORRESPONDENT:** see DIVORCE.

**CORFE CASTLE**, a large village and parish in the "isle" of Purbeck, Dorsetshire, Eng., is about 18 mi. E.S.E. of Dorchester. Pop. (1961) 1,381. The geology and scenery are varied, the principal features being two parallel ridges of chalk and Purbeck limestone enclosing fertile tracts, to the north of which lie sandy heathlands around Poole harbour. The region was exploited in Roman times for the pottery, "marble" and shale industries, and there are many early historic remains, including well-marked Celtic farmstead earthworks at Kingston. The great house at Encombe was the home of the celebrated Lord Chancellor Eldon.

The castle, dramatically situated to command a gap in the chalk hills, has been in ruins since it was dismantled by Parliamentary forces in 1646 after its heroic defense for six weeks by Lady

Banks. Much of its fabric dates from the 12th and 13th centuries, but there is early Norman work in the middle ward. There is little save legend to connect its site with the lodge of Elfrida or Aelfthryth at *Corfe gate* where her stepson, the Saxon king Edward the Martyr (*q.v.*; to whom the church is dedicated), was murdered in 978.

The town that grew up beneath the castle was once important enough to send two members to parliament (until 1832), and became a corporate borough; it was the centre of the Purbeck marble industry which reached its peak in the 14th century, when the stone was widely exported for interior embellishments, shrines, and tombs like that of Edward, the Black Prince. Quarries are reopened only for repair work, but the mining of clay continues in the heathlands. The stone-roofed village is a tourist attraction.

(R. A. H. F.)

**CORFINIUM**, in ancient Italy, the chief city of the Pacligni (*q.v.*), about 7 mi. N. of Sulmo (mod. Sulmona) in the valley of the Aternus (Aterno) river, near the modern village of Corfinio in the *regione* of Abruzzi and Molise. It is first recorded in Roman history in the Social War (90–89 B.C.), when it was adopted by the Italians as the capital and seat of government of their newly founded state under the name Italia. Thereafter it became a *municipium* (*q.v.*). In 49 B.C. L. Domitius Ahenobarbus tried in vain to hold it against Julius Caesar. Situated on the Via Valeria, and an important road centre in the imperial period, it was a town of some size. The origin of the imposing church of S. Pelino may be traced to the end of the 5th century A.D. when it was the cathedral of the see of Valva, the town which succeeded Corfinium.

See R. Gardner in *Papers of the British School at Rome*, vol. ix, 89 (1920).

**CORFU** (modern Gr. KERKIRA; Lat. *Corcyra*), an island of Greece in the Ionian sea, separated from the coast of Epirus by a strait from 2 to 15 mi. broad. With some small islands it forms a *nomos* (department) of modern Greece. The name Corfu is an Italian corruption of the Greek *koruphai* ("crests"). Its length is about 58 km. (36 mi.), its greatest breadth about 27 km. (17 mi.). The island consists of three districts, of which the northern is mountainous, the central undulating and the southern low lying. All are of limestone formation and have picturesque scenery. There are two principal ranges: one, the highest peak in which is Pantokrator (2,972 ft.) in the northeast, lies east and west from Cape St. Angelo to Cape St. Stefano; the other culminates in Santa Decca (Greek *oi Ayioi Deka*, "the Ten Saints"). Pop. (1951) 100,957 (isl.), (1961) 101,770 (*nomos*). Area 593 sq.km. isl.; 643 sq.km. *nomos* (229 sq.mi. isl.; 248 sq.mi. *nomos*).

Corfu is well watered, widely fertile and the most beautiful of the Greek isles, but the prevalent olives give monotony to its colouring. Myrtle, arbutus, bay and ilex form thick brushwood. Figs, oranges, lemons, vines and maize are cultivated and olive oil, fruit, grain and wine are exported. Stock is raised and there is fishing. In the town of Corfu, soap and textiles are manufactured.

The common form of land tenure is the *colonia perpetua*, by which the landlord grants a lease to the tenant and his heirs forever in return for a rent fixed at a certain proportion of the produce. The capital is the only city on the island, but there are numerous villages. Near Gastouri stands the Achilleion palace, built for the empress Elizabeth of Austria and later owned by William II of Germany.

The town of Corfu (pop. [1951] 27,431) stands on the broad part of a peninsula within the central bay of the east coast. The steep twin-peaked citadel has the sea on two sides and is cut off from the town by a natural gully with an artificial salt-water ditch at the bottom. The old fortifications were built in 1550 by the Venetians. The town is a labyrinth of narrow, tortuous, up-and-down streets, but there is a wide esplanade between the town and the citadel and a promenade by the seashore toward the suburb Castrades. The palace, of white Maltese stone, was built in 1816 by Sir Thomas Maitland, lord high commissioner of the Ionian Islands, 1815–24. A few houses survive from Venetian times with

traces of past splendour, but the modern buildings are in French or Italian style. The city is the seat of a Greek metropolitan and a Roman Catholic bishop. The cathedral is dedicated to Our Lady of the Cave, and St. Spyridon's church contains the tomb of the patron saint of the island. The church of St. Anthony is the only Roman Catholic church left and there were by mid-20th century only a few Roman Catholics in the city. The theatre was built between 1663 and 1690; the museum was transferred to the palace in 1931 and the library, which was housed in the gymnasium, was destroyed in World War II, together with many of Corfu's other buildings. The former university, inaugurated in 1824 through the efforts of Frederick North, 5th earl of Guilford, was disestablished when the British protectorate ceased.

The site of the ancient city is about 1½ mi. to the southeast of Corfu, between the lagoon of Calichiopulo and the bay of Castrades, the ancient Hylleic port and the port of Alcinous, the legendary king of the Phaeacians. The circular tomb of Menecrates (discovered in 1843) and the remains of the archaic Doric temple of Artemis (of which the famous Gorgon pediment was placed in the museum) are noteworthy. Of ancient Cassiope, the name is preserved by the village of Cassopo, but the temple of Zeus Cassius has disappeared. There are numerous monasteries on the island.

**History.**—In local tradition Corcyra was the Homeric island of Scheria, the home of the Phaeacians. The Corinthian colony was established about 734 B.C., supplanting a previous settlement of Eretrians. The position of Corcyra on the highway between Greece and the west favoured rapid growth and freedom of action, and its people, contrary to the usual practice of Corinthian colonies, maintained an independent and even hostile attitude toward the mother city. About 664 B.C. their fleets fought the first naval battle recorded in Greek history. The Corinthian tyrant Periander (c. 600) temporarily reduced Corcyra, installed a viceroy and induced the island to join in the colonization of Apollonia and Anactorium. However, it regained its independence and devoted itself to purely mercantile policy. During the Persian invasion of 480 it manned 60 ships but took no active part. In 435, in a quarrel with Corinth, it sought assistance from Athens. This was one of the immediate causes of the Peloponnesian War (q.v.), in which Corcyra was a useful naval station and supply base for the Athenians though it was twice nearly lost by internal feuds. On each occasion, 427 and 425, the popular party ultimately won. After a third rising in 410 it quit the war. A fresh Athenian alliance (375) resulted in hostilities with Sparta. Within the 25 years following 303, the island changed hands among Cleonymus the Spartan, Cassander, Agathocles of Syracuse, Pyrrhus of Epirus, Demetrius Poliorcetes and Pyrrhus again. Seized by the Illyrians in 229, Corcyra was delivered by the Romans, who retained it as a naval station and made it a "free state." In 31 B.C. Octavian used it as a base against Antony, but his victory foundation, Nicopolis, soon outrivalled it and Corcyra lost its prestige.

With the rise of the Norman kingdom in Sicily and the Italian naval powers, Corcyra again became a frequent object of attack. The Byzantines lost it successively to Robert Guiscard (1081–85), to Roger II of Sicily (1147–54) and to Genoese privateers (1197). These last were expelled by the Venetians after the establishment of the Latin empire in Constantinople, but in 1214 the island was annexed to the Greek despotate of Epirus. Thence it passed to Manfred of Sicily (1259) and subsequently to the Angevins of Naples (1267). From these the Venetians acquired a form of protectorate over Corcyra in 1386 and full sovereignty in 1401.

Though they encouraged the Corfiots to cultivate the olive, the Venetians prevented them from competing with Venice commercially, and the island suffered occasionally in the republic's wars with the Turks. The Greek population meanwhile was increased by refugees from the mainland and in 1732 the first modern Greek academy was founded in Corfu.

On the dismemberment of the Venetian republic under the treaty of Campo Formio (1797), Corfu was assigned to France, but the French garrison was expelled by a Russo-Turkish armament in 1799. Then, for a short time, Corfu was the capital of

the ephemeral Septinsular republic. Incorporated in the French empire under the treaty of Tilsit (1807), it was attacked by a British fleet in 1809. When the Ionian Islands were placed under a British protectorate by the treaty of Nov. 5, 1815, Corfu became the seat of the British high commissioner. Though the local senate and assembly were retained, British administration, although it improved conditions, displeased the inhabitants by its strictness and in 1864 Corfu was ceded with the other Ionian Islands to the kingdom of Greece, in accordance with the wishes of the populace. (See IONIAN ISLANDS.)

The neutral status of Corfu, stipulated in the treaty of cession to Greece, was maintained throughout the Balkan Wars. In World War I, however, as the Serbian resistance was collapsing on the Balkan mainland, French troops landed in Corfu in Jan. 1916, and within a month about 80,000 Serbs had joined them, with a number of Montenegrins. Corfu then became the seat of the Serbian government in exile. The pact of Corfu, which proclaimed the union of the South Slavs or Yugoslavs, was signed on July 20, 1917 (see SERBIA).

In 1923 Corfu was the scene of an incident which first tested the strength of the League of Nations. On Aug. 27 Gen. Enrico Tellini, the Italian member of the delegation appointed to settle the Greek-Albanian frontier under the auspices of the conference of ambassadors in Paris, was murdered on Greek soil, together with members of his staff. On Aug. 29 the Italian government sent the Greek government a humiliating ultimatum and on Aug. 31 Italian forces bombarded and seized the town of Corfu. The Greek government, though willing to accept several clauses of the ultimatum, appealed to the League of Nations on Sept. 1. The League referred the dispute to the conference of ambassadors, which decided (Sept. 7–13) substantially in favour of Italy, although there was as yet no evidence that the assassins were Greeks, still less that their crime was officially condoned. Greece accepted the decision, and the Italian occupation of Corfu ended on Sept. 27.

The peace of the island was next disturbed in World War II, when the town was bombed by the Italians and later occupied (1941–44) by the Italians and Germans in succession. After the liberation of the Greek mainland in the autumn of 1944, Corfu received a large number of refugees from Epirus when the Communist-controlled army of E.L.A.S. (see GREECE: Modern History) swept the loyal Greek forces of Gen. Napoleon Zervas off the mainland in the last week of December. Most of these returned to their homes when E.L.A.S. was defeated by British intervention. In 1946 the Corfu strait, which narrowly separates Greek from Albanian territory, was the scene of more than one attack by the Albanian Communist regime (using coastal artillery and mines) on British naval vessels. Corfu was not, however, directly involved in the series of guerrilla operations along the Greek-Albanian frontier during the Communist rebellion in Greece (1947–49). The island escaped the earthquakes which destroyed large parts of the southern Ionian Islands in Aug. 1953.

The text of most documents relevant to the crisis of 1923 is printed in *L'Europe nouvelle* (Oct. 6, 1923). For incidents of 1946–49 see the judgments of the International Court of Justice, *Corfu Channel Case*, 5 vol. (1949–50). See also A. Philippon, *Die gr. Landschaften*, vol. II, ch. ii, pp. 422 ff. (1959). (J. L. Mv.; C. M. Ws.; W. G. F.)

**CORI, CARL FERDINAND** (1896– ), biochemist and Nobel prize winner, was born in Prague, Czech., on Dec. 5, 1896. His scientific training was received in Europe (M.D., German University of Prague, 1920) but he emigrated to the United States soon after his graduation and became a naturalized citizen in 1928. After nine years as a biochemist at the Institute for the Study of Malignant Disease in Buffalo, N.Y., he became professor of pharmacology and biochemistry at the Washington university school of medicine, St. Louis, Mo., in 1931, and was appointed chairman of the biochemistry department of that institution in 1947.

His investigations have been of fundamental value in biochemistry and medicine. Most of his scientific work has been carried out in collaboration with his wife, Gerty Theresa (Radnitz) Cori (1896–1957), and they were jointly awarded the Nobel prize in medicine in 1947 for their studies of the metabolism of carbohydrates. They shared the award with Bernardo A. Houssay (q.v.).

of Argentina. The Coris have been concerned with the study of the detailed chemistry of the enzymic reactions involved in the conversion of glycogen to lactic acid. Noteworthy have been the isolation of the "Cori ester," glucose-1-phosphate; demonstration of the in vitro enzymic synthesis of glycogen from this intermediate; the in vitro effects of hormones on enzymic activity; and studies on the mode of action of the individual enzymes involved in lactic acid formation. (E. A. Es.)

**CORI**, a town and episcopal see of the province of Latina, Lazio region, Italy, 45 km. (28 mi.) S.E. of Rome, lies on the lower slopes of the Volscian hills (Monti Lepini) overlooking the coastal plain. Pop. (1961) 9,269 (commune). The ancient Cora, traditionally a Latin foundation, played an active part in Rome's early wars with the Volsci and the Aurunci, but the site lost much of its importance when the Appian Way was built in 312 B.C., 10 km. (6½ mi.) to the southwest. Sacked by the partisans of Marius and restored by Sulla, its later classical history was uneventful. In the 15th century, under the church, it enjoyed a further period of relative prosperity, but by 1811 its population had dwindled to 3,800. It was badly damaged in World War II. On the summit of the upper town stands the little Doric tetrastyle temple of Hercules (89–80 B.C.). Below, terraced down the hillside, are three concentric *enceintes* of cyclopean masonry, established almost certainly on a single occasion, although containing work of three distinct qualities and, presumably, dates, of which the latest may be attributed to the years following the final recapture of the place by Rome from the Volsci, about 330 B.C. Below the town there is a fine single-arched bridge of republican date, the Ponte della Catena. The church of Sta. Oliva has an elegant two-story cloister (1466–80), and there are 15th-century frescoes of the Roman school in the chapel of the Annunziata outside the town. (J. B. W.-P.)

**CORIANDER**, the fruit, improperly called seed, of an umbelliferous plant (*Coriandrum sativum*), a native of the south of Europe and Asia Minor, but cultivated in Europe, where it is also found as an escape from cultivation, as it is in many parts of the United States. The plant produces a slender, erect, hollow stem rising one to two feet in height, with bipinnate leaves and small flowers in pink or whitish umbels. The fruit, globular and externally smooth, having five indistinct ridges, is scarcely separable into its sections (mericarps).

Coriander is one of the few umbelliferous plants producing fruit with a concave face. It was once used in medicine as an aromatic and carminative, but its only modern use is to mask the unpleasant taste or odour of other drugs. The active principle of its volatile oil (coriandrol) is highly aromatic and a favourite ingredient in hot curries and sauces. The fruit is also used in confectionery and as a flavouring ingredient in liqueurs. The young leaves and shoots are frequently used in soups. (N. Tr.)

**CORINNA** (date uncertain), lyric poet of Tanagra in Boeotia, is the only writer in the Boeotian dialect of Greek of whose work any distinct idea can be formed. A number of anecdotes preserved by later writers make her out to have been a contemporary, a competitor and even a teacher of Pindar, in which case she must have been active about 500 B.C., but there is nothing in the fragments of her poetry or in any even approximately contemporary source to confirm this inference. The fragments, to which 20th-century papyrological discoveries made considerable additions, are written in an orthography which seems to have been current in Boeotia in the 2nd century B.C.; and though it is possible that the texts have been transcribed from an older orthography, such as is known to have been current in Boeotia in the 5th century, there is no conclusive evidence of this. The metrical evidence is as inconclusive as that of the orthography; on the one hand it is clear that Corinna's metrical ideas were strongly influenced by Anacreon, but on the other it has been argued that she was also influenced by Euripides. Her style is so simple as to be all but timeless, and her chief subjects are the local legends of her native Boeotia (her self-satisfied provincialism according to the anecdotists exasperated Pindar to such a pitch that he called her a sow; i.e., a Boeotian). Poems in a manner very like hers, but dealing with non-Boeotian legends, were found among papyri in

the 1950s; the papyri do not explicitly ascribe these poems to Corinna, and some scholars have therefore been inclined to doubt whether she wrote them. Further evidence was still needed to settle this problem; and also to decide the fascinating question of Corinna's date: certainty on this point would assist in the solution of several other problems, literary and metrical.

Lobel (ed.), *Oxyrhynchus Papyri*, xxiii, nos. 2370–74 (1956); Sir Maurice Bowra, *Problems in Greek Poetry*, pp. 54–65 (1953); M. F. Galiano, "La lirica griega a la luz de los descubrimientos papirológicos," *Actas del I Congreso Español de Estudios Clásicos*, pp. 120–126 (1958). (JN. A. D.)

**CORINTH, LOVIS** (1858–1925), German painter, a leader of the *Sezession* group and a great influence on modern German art through his teaching and writing, was born at Tapiau, East Prussia, on July 21, 1858. His training was academic and taken after 1884 in Paris under A. W. Bouguereau. There, however, he was influenced both by the French Impressionists and by the work of Rubens, and after he settled in Berlin in 1900 his pictures, sombre at first, gained brilliance from the former and vitality from the latter. Thus equipped he led the *Sezession* movement against the academic school in Berlin, with the collaboration of M. Slevogt and M. Liebermann. Though best known for his landscapes of the Walchensee area and for his portraits, he also painted religious scenes, often violent ones such as the "Golgotha" altarpiece (1909–11, Tapiau) and a "Deposition" at Leipzig (1907). He also painted themes from antiquity and studies from the nude and made etchings and lithographs. He died on July 17, 1925, at Zandvoort, Neth. See also **PAINTING: Expressionism and the German School**.

See A. Kuhn, *Lovis Corinth* (1926); L. Corinth, *Selbstbiographie* (1926); Gert von der Osten, *Lovis Corinth* (1955). (D. C. T. T.; X.)

**CORINTH** (Gr. KORINTHOS), a city of Greece. The ancient Hellenic city (see *History*, below) grew (after c. 1100 B.C.) from settlements round the citadel or Acrocorinthus, 2.5 km. (1½ mi.) S. of the isthmus which connects the Peloponnese and central Greece and separates the Saronic and the Corinthian gulfs (see **CORINTH, ISTHMUS OF**). The citadel rises precipitously above the old city to a height of 1,886 ft. and commands all routes into the Peloponnese.

**Modern Town.**—The modern town of Corinth, the chief town of the *nomos* of Corinth (Korinthia) and an episcopal see, is situated on the western side of the isthmus, 5.6 km. (3½ mi.) N.E. of the Hellenic city. Pop. (1961) 15,892. It was refounded in 1858 when old Corinth (i.e., the post-Justinian city) was destroyed by earthquake, and was itself almost wholly destroyed by earthquake in 1928. It is connected by railway with Athens (92 km.; 57 mi.), with Patras (140 km.; 87 mi.) and with Nauplia (64 km.; 40 mi.), the capital of Argolis, and also by main roads. After the opening of the ship canal in 1893 Corinth had sea communication with Patras, the Ionian Islands and the west coast as well as with Athens. It has few local resources. Its chief exports are currants (which have their name from the town), olive oil, silk and cereals from the northeast Peloponnese.

Corinth *nomos* includes the resorts of Loutraki (hot springs) and Xilokastron, the ruins of Sicyon (q.v.) and Stymphale and the currant-packing station and port of Sikionia.

**Archaeology.**—The ancient city occupies two natural terraces at the northern foot of Acrocorinthus to which it is joined in a circuit wall about 6 mi. in circumference. With its principal port, Lechaëum, on the Corinthian gulf (near the earlier site of Korakou), the city was connected by two parallel walls and a paved highway which led past the large public baths of Eurycles (2nd century A.D.) to the propylaea, the entrance to the agora. This propylaea was in its earlier form a long shallow building with five arches but was replaced after the refoundation of 46 B.C. by a single entrance in the form of a Roman triumphal arch. Immediately to the east lay the famous fountain house of Peirene which owed the most splendid of its many remodelings to the generosity of Herodes Atticus (q.v.; c. 175 A.D.). Most of the substantial remains in the agora, including the artificial terracing, the central row of shops and the bema or rostrum, scene of St. Paul's trial before Gallio, are also works of the Roman period, but it

mond, "The Heraeum at Perachora and Corinthian Encroachment," *Annual of the British School at Athens*, 49 (1954); E. Will, *Korinthiska*, with full bibliography (1955). (W. G. F.; N. G. L. H.)

**CORINTH, ISTHMUS OF** (Gr. *ISTHMOS KORINTHOU*), in Greece, dividing the Gulf of Corinth from the Saronic gulf. It is composed of heavily faulted limestone rocks, which rise from the south in terraces to a central plateau a little under 300 ft. above sea level. Its thin limestone soils are very parched and afford little opportunity for agriculture, which is generally limited to poor crops of wheat and barley, though here and there, on the upper edges of the terraces and along the stream banks, vineyards will thrive. Away from the fields the land carries only a light vegetation of stunted shrubs and occasional open woods of dwarf Aleppo pine. Ships were dragged across the isthmus in ancient times. Nero, in A.D. 67, began a canal through it. A ship canal begun in 1881 was opened in 1893 with its western entrance about 1½ mi. N.E. of New Corinth. It is 3.9 mi. long, 69 ft. broad at the bottom and 26 ft. deep. It shortens the journey from the Adriatic to Piraeus by 202 mi. for such vessels as can navigate it. Traces of an ancient wall may still be seen parallel to the canal. Just to the south of it lies the fortified sanctuary of Poseidon, where the Isthmian games were celebrated. The Gulf of Corinth is an inlet of the Ionian sea, separating Peloponnesus from mainland Greece. It is 80 mi. long and between 3 and 20 mi. wide. (Wm. C. B.)

**CORINTHIAN ORDER:** *see* ORDER.

**CORINTHIANS, EPISTLES TO THE**, two books of the New Testament addressed by Paul the apostle to the Christian congregation in Corinth, Greece, where he worked for more than 18 months after his apparently not very successful stay in Athens. By supplementing the connected report of Paul's activities at Corinth in Acts xviii with the incidental information in the two Epistles to the Corinthians, a more detailed picture of the historical background to these Epistles can be obtained.

**Historical Background.**—Paul arrived alone in Corinth (I Thess. iii, 1) and lived in the house of Aquila and Priscilla, a Jewish couple who may have been Christians before they were driven out of Rome by the emperor Claudius' decree. Paul taught first in the synagogue and then in the private house of a gentile "worshipper of God" nearby. His teaching seems to have been very successful mainly with the lower classes of the pagan population (*cf.* I Cor. i, 26–28; xii, 2), but a few Jews, including Crispus, the ruler of the synagogue, joined the Christian congregation.

When Paul had been in Corinth for 18 months he was accused by the Jews before Gallio (a brother of the philosopher Seneca), the Roman proconsul of Achaia, who refused to concern himself at all with a purely Jewish affair. Paul however shortly afterward felt that he should leave Corinth, together with Priscilla and Aquila.

Paul went first to Palestine, and then for three years to Ephesus, where Priscilla and Aquila had gone directly from Corinth. They had found there an Alexandrian Jew called Apollos who had learned "the way of the Lord" but knew only the baptism of John. After receiving their further instruction Apollos went with an introduction from them to Corinth, where he continued Paul's work ("I planted, Apollos watered," I Cor. iii, 6). While at Ephesus Paul must have sent to Corinth a letter which is no longer extant (*cf.* I Cor. v, 9) and the Corinthian reply must have posed various moral and doctrinal questions (*cf.* I Cor. vii, 1; viii, 1; xii, 1). This letter may have been brought personally by Christians from Corinth (perhaps by "Chloe's people," I Cor. i, 11, or by Stephanas, Fortunatus and Achaicus, I Cor. xvi, 17); in any case Paul was informed by Corinthian visitors about the affairs of their congregation (I Cor. i, ii; v, i; xi, 2, 18). This letter from Corinth and the news brought verbally led Paul to write the first extant Epistle to the Corinthians before Pentecost in the year of his departure from Ephesus (*i.e.*, probably A.D. 56). Before writing Paul had apparently sent to Corinth his close friend Timothy, who had previously been his companion there, in order to remind them what they had learned from him; as Paul expects that Timothy will arrive after the letter, it must have

been written in response to sudden need and sent by the quickest route to Corinth.

After sending this letter Paul must have received bad news from Corinth, perhaps when Timothy returned to him, so he decided to pay another visit to the city (II Cor. ii, 1; xii, 14; xiii, 2). But this short stay must have caused him grief (II Cor. ii, 1), for a member of the church wronged him, or rather the whole congregation, in some way which is not made explicit (II Cor. ii, 5; vii, 12). After departing earlier than he had intended Paul wrote a letter "with many tears" (II Cor. ii, 4; vii, 8) asking for the punishment of the wrongdoer, and at the same time sent his disciple Titus to Corinth. As a result the majority of the Corinthians excluded the wrongdoer from the congregation (II Cor. vii, 6 ff., 14). But Paul was so eager to get fuller news that he left his preaching in Troas and went into Macedonia, where he met Titus and heard from him that the situation in Corinth was much improved. Paul then wrote the second extant Epistle to the Corinthians in the autumn of A.D. 56 (*i.e.*, about six months after writing the first Epistle). It is not known how the second epistle was received by the Corinthians, but at least there is no mention of any difficulties at Corinth when Paul wrote his Epistle to the Romans six months later during a stay in Corinth.

**First Epistle.**—This is probably the fourth of the extant letters of Paul, coming chronologically after the two Epistles to the Thessalonians and the Epistle to the Galatians. It differs in structure from his other letters in that there is no real sequence of thought, several unconnected subjects being treated in succession. This is due to the fact that he is answering the miscellany of questions which had been put to him by the Corinthians in their letter or through the members of their congregation who had visited him. The Epistle however is ruled by one central theme. The newly converted pagans were still strongly influenced by the conviction that man must be delivered from his material existence by receiving some supernatural saving quality, while his moral behaviour was unimportant to his salvation. In his Epistle Paul tries to combat this "gnostic" attitude still lingering in the minds of the Corinthian converts who had not really understood his message of the saving action of God through the historical Jesus Christ at the end of this transitory evil age, and had not been convinced that man could be renewed by this eschatological action of God and thereby enabled to lead a new life.

**Summary.**—Paul puts in the foreground the "word of the cross" (I Cor. i, 18), the "gospel . . . by which you are saved" (xv, 1 ff.), which is his central proclamation in dealing with the single problems that have arisen in the life of the newly converted congregation. The Corinthians were divided into several groups, respectively called after Paul, Apollos, Cephas and Christ (i, 12), the first three being the baptizers of each group, though the special character of the last group is not clear. Paul condemns this splitting up of the one body of Christ, and points out that the identity of the person who preached them the gospel or baptized them is quite irrelevant (i, 12–iv, 21). Marriage with one's stepmother (v, 1–13), going to law before pagan judges (vi, 1–11) and sexual intercourse with a prostitute (vi, 15–20) are all said to be out of the question for members of the body of the crucified Christ. Against the inclination of some Corinthian Christians to reject marriage entirely Paul claims that marriage is necessary and indissoluble for those who have not the gift of continence, but as the end of the world is very near it would be better not to marry if possible (vii, 1–40). Joining in sacrificial meals with pagans is not in itself harmful to Christians, but if taking part in such meals offends the conscience of the weak who cannot convince themselves that sacrificial meat has no connection with demons, then these meals should be avoided (viii, 1–xi, 1).

Paul then turns to three questions concerning the assemblies of the congregation. He defends the oriental custom of praying with the head covered against the desire of women members of the church to appear bareheaded in the assembly (though his reasoning here is hardly convincing to the modern mind!) and he stresses the necessity of courtesy and respect when they come together for "the Lord's Supper" by reminding them of the con-

nection between this communal meal and the death of Christ (xi, 2-34). As the Corinthians have a high regard for ecstatic speech in their assemblies, Paul, who himself has the gift of speaking with tongues, points out that such speech is not to be encouraged because it is unintelligible to the congregation as a whole, which is thus not edified by it (xii-xiv). It is in connection with edification that the famous chapter in praise of love (or charity) is inserted (xiii). Finally, as some of the Corinthians were denying the resurrection of the dead, including the resurrection of Christ, Paul stresses the historical fact of Christ's resurrection as accepted by all the apostles and argues from it that the future resurrection of all Christians is a certain hope (ch. xv). The final chapter concludes the letter with personal news and greetings (ch. xvi).

**Unity of the Epistle.**—The apparent contradictions in Paul's advice about the eating of sacrificial meat, which is both forbidden in some circumstances and permitted in others, has led some scholars to suppose that this Epistle is a combination of two or three separate letters. This hypothesis is strengthened by the fact that there is little connection between the different sections of the Epistle and the fact that a lost letter did precede this "first" Epistle. But the difficulties raised by this theory are greater than the seeming inconsistencies which it is supposed to explain, and no one has been able to give a satisfactory reason why two or three separate letters should have been dovetailed together to make a new one. It is more probable therefore that the first Epistle to the Corinthians has survived in its original form.

**Second Epistle.**—This letter is quite different in character from the other, for in it Paul does not deal with a series of independent subjects. Instead, the whole Epistle is a discussion with the congregation to strengthen them in their new enthusiasm for the gospel Paul had preached to them and to warn them against the opposition to him which still remains in the congregation.

**Summary.**—The first and longer part of the Epistle (II Cor. i, 1-ii, 13 and vii, 5-16) discusses the situation that has developed between the congregation and Paul. He defends his past actions, speaks of the joy the news brought by Titus gave him and explains why he has not yet paid another visit to Corinth. This argument is broken by a long defense of his own apostolic office (ii, 14-vii, 4), at the end of which he warns against co-operation with unbelievers (vi, 14-vii, 1). Again and again Paul defends himself against attacks on his behaviour in general and to the Corinthians in particular, and against criticism of his apostolic office. He contrasts the human frailty and transitoriness of the Christian teacher (iv, 7-v, 10) with the glory of his commission to preach the gospel of reconciliation (v, 11-21). The next two chapters, which follow without any clear connection, contain two parallel summons to collect money for the poor of the Jerusalem church (viii-ix). Paul says he will send Titus with two others to Corinth for this purpose, and praises the congregation for their enthusiasm in the matter. Then follows a severe warning to those in the congregation who attack Paul and doubt his apostolic office (x-xiii); Paul calls them "superlative apostles" (xi, 5), and threatens to take strong measures against them as soon as he comes to Corinth. He warns the congregation of the danger of listening to such persons. Against these attacks Paul defends himself by pointing to his unselfishness and asserting that he can boast of all the distinctions which his opponents also possess, though such distinctions are quite irrelevant (hence he admits to speaking "as a fool," II Cor. xi, 17). It is in this context that Paul lays claim to ecstatic experiences (xii, 1-4) and gives a sober list of his apostolic sufferings (xi, 23-28). The Epistle ends with the well-known triadic formula: "The grace of the Lord Jesus Christ and the love of God and the partaking in the Holy Spirit be with you all" (xiii, 14).

**Composition of the Epistle.**—As the connections of thought are not always clear, in spite of the all-pervading theme, it has been suggested that this Epistle too is composed of two or three original letters. In particular some scholars maintain that II Cor. vi, 14-vii, 1 either could not have been written by Paul or must be inserted from another context. It is still more strongly maintained that II Cor. x-xiii cannot have belonged originally to this Epistle but must be part either of the letter Paul wrote between his first

and second Epistles to the Corinthians (the "hypothesis of the four chapters") or of a letter written after the second Epistle. But here too the difficulties raised by these hypotheses are greater than the problems they are supposed to solve, so it seems wiser to regard the traditional form of the text as original, although some difficulties remain puzzling.

**Paul's Opponents.**—The much-discussed historical problem of the second Epistle to the Corinthians is the identity of the opponents whose attacks Paul criticizes in the first part of his letter and whom he assails personally in the three final chapters. It does not appear that they were "Judaizers," for they did not demand the fulfillment of the whole law like the "Judaizers" condemned in the Epistle to the Galatians. Nor does it seem that they were only the "gnostics" whose misinterpretation of the Christian message is corrected in the first Epistle to the Corinthians. Their fierce polemic against the apostolic office of Paul, their pride in their own Jewish privileges and their personal knowledge of Jesus (II Cor. xi, 22 ff.; xii, 11 ff.; v, 16) show that these opponents must have been connected with the Jerusalem church. It is likely that after Paul's first visit to Corinth Jerusalem Christians had come to Corinth and attacked Paul's apostolic position from the stronghold of their own connections with Jesus and their irreplicable Jewish behaviour. On this hypothesis Paul is defending himself in the second Epistle to the Corinthians against both gnostic and Jerusalem Christian opponents.

**Importance of the Epistles.**—The Epistles to the Corinthians have a fourfold importance. In them Paul provides chronologically the earliest information about Jesus and the beginnings of the church when he quotes from the oldest tradition about the Last Supper (I Cor. xi, 23 ff.) and about the first appearances of the risen Christ to the disciples (I Cor. xv, 3 ff.). Both Epistles show the difficulties caused in an early pagan-Christian congregation by the necessity of combining the implications of a religion that proclaims both a historic revelation and the imminent end of the world with the traditions of naturalistic piety inherited by the pagans. The consequence of this difficulty is seen in the abuses and exaggerations that occur in the life of the congregation or of the individual Christian not only in their dealings with sexual relationships, law suits and congregational assemblies but also in their inability to understand the proclamation of the resurrection of Christians, in their unwillingness to accept Paul as he is and in their underrating of those functions in the life of the congregation that are not ecstatic.

Still more important is the assurance with which Paul distinguishes between the Christian belief in God's salvation through a historic act of reconciliation and deliverance and the naturalistic aim of self-redemption in the Hellenistic religions. It is especially instructive to see how he masters the difficulties arising from the necessity for a completely new approach to nearly all the moral problems that beset the life of the young Christian community. The second Epistle reveals details of Paul's missionary methods, his biography, his character, his personal difficulties and the deep power of his faith. Thus these two letters are an important source both for the history of early Christianity and the life of Paul on the one hand and for the essence of the Christian faith on the other. CORIOLANUS, GAIUS (GNAEUS) MARCIUS (5th cent.

ture B.C.), legendary Roman hero of patrician descent. According to tradition, his surname was due to his bravery at the siege of Corioli (493 B.C.) in the war against the Volsci. In 491, when there was a famine in Rome, he advised that the people should not share the corn obtained from Sicily unless they would consent to the abolition of their tribunes. For this he was accused by the tribunes and, being condemned to exile, took refuge with the king of the Volsci and led the Volscian army against Rome. In vain the Romans prayed for moderate terms. At last, however, persuaded by his mother, Veturia, and his wife, Volumnia, he led back the Volscian army. He either died at an advanced age in exile among the Volsci or was put to death by them as a traitor or took his own life.

The legend is open to serious criticism. At the traditional date (493 B.C.) Corioli was not a Volscian possession but a Latin city in alliance with Rome, while it is improbable that the Volscians would have succeeded in reaching the gates of Rome immediately after Rome and the Latins had strengthened their powers of resistance through the Cassian treaty of 493. Further, Livy himself states that the chroniclers knew nothing of a campaign against the Volsci in which Coriolanus is said to have served. The conquest of Corioli by Coriolanus seems to have been invented to explain the surname. Many details of the story are suspect (e.g., the flight of Coriolanus to the Volscian king bears a suspicious likeness to the story of Themistocles, while his clash with the tribunes is more typical of the 2nd than of the 5th century B.C.), but the legend at least testifies to the fact that in the early 5th century Rome suffered from Volscian pressure and from a shortage of corn.

See Plutarch's *Life*; Livy, II, 34-40; Dionysius of Halicarnassus, vi, 92-4, vii, viii; Cicero, *Brutus*, x-xi. The story is the subject of Shakespeare's *Coriolanus*. For a critical examination of the story see T. Mommsen, *Römische Forschungen*, II, pp. 113 ff. (1864-79); W. Schur, in Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, supplement v., pp. 653-660 (1931); E. T. Salmon, *Classical Quarterly*, for 1930, pp. 96 ff. (H. H. Sp.)

**CORIOLIS, GASPARD GUSTAVE DE** (1792-1843), French engineer and mathematician, who described the inertia force called after him the Coriolis force, was born in Paris on May 21, 1792. In 1808 he entered the École Polytechnique and continued his studies at the Écoles des Ponts et Chaussées, graduating in highway engineering. Shortly thereafter (1816) he joined the staff of the École Polytechnique as assistant professor of analysis and mechanics, a position he held until 1838, when he became director of studies. He was elected a member of the mechanics section of the Academy of Sciences in 1836. He died in Paris on Sept. 19, 1843.

Coriolis was prevented by ill-health from realizing his full potentialities as a scientist. Despite this handicap, he made a number of significant contributions in his field. The one for which he is best known is described in the *Journal de l'École Polytechnique*, vol. xv (1835), under the title "Sur les équations du mouvement relatif des systèmes de corps." In this paper he showed that the ordinary laws of motion of bodies may be used in a rotating frame of reference if an inertia force, acting to the right of the direction of motion of the body for counterclockwise rotation of the frame, or to the left for clockwise rotation, is included in the equations of motion. This result is of great significance, particularly in meteorology and oceanography, for motions over the earth's surface are studied relative to the earth, which is a rotating frame of reference. The Coriolis force appears prominently in practically all studies of the dynamics of the atmosphere and oceans; it is also an important factor in ballistics.

See MOTION, PRINCIPLES AND LAWS OF.

Coriolis' works include two substantial treatises: *Calcul de l'effet des machines* (1829), republished posthumously under the title *Traité de la mécanique des corps solides*, etc. (1844); *Théorie mathématique des effets du jeu de billard* (1835). (E. W. He.)

**CORIPPUS, FLAVIUS CRESCONIUS** (6th century A.D.), important Latin epic poet and panegyrist. Of African origin, Corippus later migrated to Constantinople; he was for a time a *grammaticus* and may subsequently have been a civil servant. His literary reputation is based on two poems. The *Johannis*, an epic hexameter poem in eight books, treats the campaign con-

ducted against the insurgent Mauretanians by John Troglita, the Byzantine commander, and is the principal source for these events. The poem, written about 550, also shows the tenacity of the classical tradition in Africa, and the continuance of the poetic revival which took place under Vandal rule. Corippus succeeds in achieving a pleasing fluency of style: he closely models his epic on the *Aeneid* of Virgil; while some modifications are imposed by his Christian viewpoint, he introduces many traditional features of the epic such as the catalogue and the embodied narration of events prior to the poem's commencement. Claudian's influence is also apparent, and there are echoes of Ovid, Lucan and Statius and some imitation of Dracontius. Corippus' other poem, *In laudem Justinii*, the four books of which eulogize Justinian I's successor Justin II, was written after the arrival of Corippus in Constantinople when he found himself in straits. This rhetorical poem contains elaborate description and excessive detail; it is interesting for the account which it gives of the death of Justinian and his successor's accession and of the embassy of the Avars. Corippus' hexameters show considerable knowledge of classical standards, and in this he may be compared with the grammarian-poet Priscian: there is however some neglect of the caesura, and quantities are sometimes distorted.

See edition by J. Partsch, *Monumenta Germaniae historica. Auctores antiquissimi*, vol. 3, part 2 (1879). (D. R. Br.)

**CORISCO**; see EQUATORIAL GUINEA.

**CORK, RICHARD BOYLE, 1ST EARL OF** (1566-1643), English colonizer of Ireland whose singular capacity for lining his pocket brought himself and his children land, power and titles, was born at Canterbury on Oct. 13, 1566. He was educated at King's school and at Bennet (Corpus Christi) college, Cambridge, and studied law at the Middle Temple. Seeing no prospect of acquiring wealth in England, he went to Ireland in June 1588, possessing only £27 3s., a diamond ring and a bracelet. He became subsheriff to John Crofton, the escheator general, and grew so prosperous that accusations of embezzlement were soon being made against him. However, the Munster rebellion (1598) temporarily ruined him; he returned to England and was employed by the earl of Essex. Charges were again brought against him, but after two months' imprisonment he cleared himself before the Star Chamber and Queen Elizabeth I appointed him clerk of the council of Munster in May 1600.

Boyle bought in 1602 the whole of Sir Walter Raleigh's estates in Cork, Waterford and Tipperary. He encouraged settlers from England, started manufactures and industries and used much of his profits for improving the towns, building bridges and castles and for maintaining free schools and almshouses. Meanwhile, his advancement was rapid. Knighted in 1603, he became a privy councillor for Munster (1606) and for Ireland (1613), and was created Lord Boyle, baron of Youghal, County Cork (1616), and earl of Cork (1620). He was appointed a lord justice in 1629 and lord high treasurer in 1631. When Thomas Wentworth (afterward earl of Strafford) became lord deputy in Ireland in 1633, Cork's power and wealth declined; he steadily, albeit quietly, opposed Wentworth but remained loyal to the English crown and interest and fought against the Irish rebels of 1641. He died at Youghal on Sept. 15, 1643.

By his second wife, Catherine, daughter of Sir Geoffrey Fenton, Boyle had eight daughters and seven sons, four of whom received independent peerages. Richard (d. 1698), as well as inheriting his father's titles, was, by virtue of his marriage (1628) with Elizabeth, Baroness Clifford in her own right, created Baron Clifford (1644) and was made earl of Burlington in 1664. Lewis (d. 1642) was created Viscount Boyle of Kinalmeaky (1628); he was killed fighting the Irish rebels at the battle of Liscarroll. In 1660 two other sons, Roger (d. 1679), baron Boyle of Broghill (1628), and Francis (d. 1699), were created respectively earl of Orrery and Viscount Shannon. Another son was Robert Boyle (q.v.), the natural philosopher and chemist.

**BIBLIOGRAPHY.**—Earl of Cork, "True Remembrances" in T. Birch (ed.), *The Works of Robert Boyle*, vol. i (1744); A. B. Grosart (ed.), *The Lismore Papers* (1886-87); D. Townshend, *The Life and Letters of the Great Earl of Cork* (1904).

**CORK** (*CHORCAICHE*), a county in the province of Munster, Republic of Ireland, is bounded on the south by the Atlantic ocean, east by counties Waterford and Tipperary, north by County Limerick and west by Kerry. With a land area of 2,880.1 sq.mi., it is the largest county in Ireland.

**Physical Features.**—The county has long east-west ridges forming uplands and, in some places, hills over 2,000 ft.; e.g., in the Bogra, Derrynasaggart and Caha mountains. However, less than three-tenths of its area is rough pasture, while farmlands climb over the ridges to as much as 800 ft. and fill the valleys of eastward-flowing rivers, such as the great Blackwater, the Bride, the Lee, the Bandon and many tributaries and lesser rivers. The hills are mainly formed of Devonian (Old Red) sandstones and the valleys of Carboniferous limestones. In the south there are also slates and shales of the Carboniferous period which stand up in ridges, though many of the lesser ridges, such as those of Cork harbour and the area immediately east of it, are formed of Devonian sandstones. The hills are anticlinal ridges, but the beds dip more steeply than the relatively gentle slopes of the valley sides. The Carboniferous rocks preserved in the valleys are generally covered with drift or alluvium, but in places appear at the surface. The broad valleys and lowlands of east and central Cork give way in the west to narrower valleys with coastal lowlands backed by high mountains. Around Bantry bay and Dunmanus bay the long peninsulas have some scenery of great fame, e.g., near Glengarriff. In this area the exceptionally mild winters allow a subtropical vegetation to survive, and the woods have a richness of moss and plant growth that resembles that of the famous woods in the sheltered valleys near Killarney. (T. W. FR.)

**History.**—The city of Cork was of Norse foundation and, with its immediate hinterland, remained for centuries virtually an independent entity. Outside that small area the Irish followed their traditional way of life. In 1127 Tordelbach O'Connor divided the kingdom of Munster (*q.v.*) between an O'Brien and a MacCarthy, the latter receiving the Kingdom of Desmond (*q.v.*). In the later 12th century, after the arrival of the Anglo-Norman invaders, Dermot MacCarthy made his submission to Henry II. The crown reserved the city of Cork, and Dermot was the last king of Desmond. Most of Desmond fell to the FitzGerald who, as earls of Desmond, became increasingly Irish in their ways. Their descendants came to grief in Tudor times, when a new type of adventurer sought to possess their lands, for their revolt in the time of Gerald, 14th earl, brought about their final ruin (*see* FITZGERALD). In 1586, under the scheme for the plantation of Munster, large estates were allocated to English "undertakers" among whom Sir Walter Raleigh, associated with Youghal, was prominent. Edmund Spenser completed the first three books of the *Faerie Queene* while leasing Kilcolman castle near Buttevant. The scheme was destroyed by Hugh O'Neill's forces in 1598 in the course of the Ulster war. A turning point of this war was marked by the failure of the Irish to relieve their Spanish allies who occupied Kinsale in 1601. Afterward the rising power was that of Richard Boyle, created earl of Cork in 1620, who had bought up ruined estates of the old Munster plantation (*see* CORK, RICHARD BOYLE, 1st Earl of). The Boyle family supported Cromwell but made advantageous terms with the restored Stuarts. Cork was the scene of much disturbance during the later 18th century and also during "the Troubles" and the Civil War in the 20th century. (HU. S.)

**Population and Administration.**—In 1961 the population of County Cork was 330,106, less than half the 854,118 of 1841. More than one-third of the people live in the city and county town of Cork (77,860) and its suburbs (37,648). Another 79,583 live in the 15 country towns or in villages, the chief towns being Cobh (5,266), Mallow (5,520), Youghal (5,043) and Fermoy (3,427). Administration is by county manager and elected county council, Cork county borough having its own city manager. The county is divided by both the Church of Ireland and the Roman Catholic Church into three diocesan units, Cork, Cloyne and Ross, the Church of Ireland having one bishop for the three. Apart from the city of Cork, the county town, there are four electoral areas, North, South, East and West Cork, each returning three

NEILL WELLS FROM PAUL POPPER

BLARNEY CASTLE, 1446. LOCATION OF THE "BLARNEY STONE," COUNTY CORK, REPUBLIC OF IRELAND

members to *dail eireann* (house of representatives).

**Industries.**—In the east and centre the county has good farms, many of them 70 ac. or more, with such crops as oats, potatoes, even wheat (though this is not prominent), and roots such as turnips and mangels and sugar beets for the factory at Mallow. The farmers' main cash resource is livestock, either for meat, or for milk sold to the creameries which are numerous in the north and west of the county. Pig rearing is traditional, though less general now than formerly because of feeding difficulties. In the extreme southwest the farms are far smaller than in the richer lowlands to the east, but around Skibbereen, and all along the south coast, there are good agricultural lands with well-tended farms of 50 ac. and more. The fishing, so prosperous at the beginning of the 20th century, has now almost disappeared, though there is salmon fishing in the rivers. Kinsale has been spoken of as a town "so depopulated, so stagnant as to be almost dead," though it now has some small factories. In the city of Cork (*q.v.*), agricultural industries such as brewing, bacon curing and flour milling are prominent, but there are also a car and tractor assembly plant, a rubber works, clothing factories, woolen mills and a large fertilizer industry. Cobh, on Cork harbour, was formerly a British naval base. Mallow is the railway junction for Killarney with a lively market trade and some small industries. Kanturk has a large hosiery works and Mitchelstown a cheese and bacon factory. Some fine tweed is still made in several rural factories near Cork, while a recent development is an earthenware factory at the village of Carrigaline. Another economic advance is the opening of a large oil refinery at Whitegate, on Cork harbour. So far tourism brings only a limited profit to the county, though Youghal and Blarney have many summer visitors.

The county has railway lines from Cork through Mallow to Dublin and Limerick; at Mallow lines run east to Waterford and west to Killarney and Tralee. (T. W. FR.)

**BIBLIOGRAPHY.**—C. B. Gibson, *The History of the County and City of Cork*, 2 vol. (1861); W. O'Sullivan, *The Economic History of Cork City From the Earliest Times to the Act of Union* (1937); M. Robertson, *County Borough of Cork and Neighbourhood*, Town Planning Report (1941); W. Holland, *The History of West Cork and the Diocese of Ross*, 2nd ed. (1950).

**CORK** (*CORCAIGH*), a county borough, seaport and county town of County Cork, Republic of Ireland, at the head of the inlet of Cork harbour, on the Lee river, 159 mi. S.W. of Dublin by road. Pop. (1961) 77,860 excluding North City and South City suburbs (37,648). It ranks as the second largest city (after Dublin) in the republic. The nucleus of the city occupies an island formed by the North and South channels, two arms of the Lee river. The name Corcaigh signifies a swamp and its original site seems to have been

in the vicinity of the cathedral of St. Finbarr, whose 7th-century ecclesiastical foundation attracted many students and votaries. According to the *Annals of the Four Masters*, a fleet burned Cork in 821; in 846 marauding Danes appeared to have been in possession of the town, for a force was collected to demolish their fortress; and in 1012 Cork again fell in flames. The Danes eventually settled and founded a trading centre on the banks of the Lee. It was anciently surrounded with a wall, an order for the repair of which is found as late as 1748 in the city council books (which date from 1610). The town under Dermot MacCarthy, Lord of Desmond, submitted to Henry II in 1172, and was granted its first charter by the king. It was subsequently held by the English for a long period. Cork showed favour to Perkin Warbeck, pretender to the English throne, when he visited Cork in 1492, a gesture resulting in the hanging of the mayor and conspirators at Tyburn, and the town being deprived of its charter. In 1649 its garrison revolted in favour of Cromwell and in 1690 it surrendered to the earl of Marlborough.

Cork has often been a principal focus of nationalist politics, and during the upheaval of 1919-20 it became the main centre of resistance to military repression. In the bitter conflict which followed the murder by a constabulary band of Lord Mayor MacCurtain and the death by a 75-day hunger strike in Brixton prison (in London) of his successor, Terence MacSwiney, the Cork city hall and most of the main shopping centre were burned down by the British in retaliation for the ambush of a military convoy. After the Anglo-Irish treaty had been concluded in Dec. 1921, the city was for a time held by the Republican forces, who would not accept the treaty settlement. Much devastation followed. Conflict between local and national authorities resulted in the temporary supersession of local councils by city and county managers. This was first tried in Cork city with such success that the Cork City Management act was passed in 1929, which restored the city council with modified powers. The county borough of Cork returns five members to *dail eireann* (house of representatives).

Natives of Cork include William Maginn, the poet; Thomas Crofton Croker (*q.v.*), the antiquary; Francis S. Mahony, "Father Prout"; and the painters James Barry and Daniel Maclise (*q.v.*).

The Protestant cathedral, built 1865-69, is in the Early French (pointed) style. Dedicated to St. Fin Barre or Finbarr, who founded the original cathedral in the 7th century, it replaced a structure erected in 1735 on the site of the ancient cathedral. The Roman Catholic cathedral, dedicated to St. Mary and conspicuous on the north side of the city, dates from 1808. Large Roman Catholic churches were built in various districts of Cork after the Catholic Emancipation act of 1829. About the same period there was agitation for a university college in Cork, and the Queen's college was opened in 1849. As University college, Cork, it became a constituent college of the new National University of Ireland in 1908. Built in Tudor style, it stands near the river where Gill abbey (12th to 16th centuries) formerly stood, and in its grounds are the Honan Collegiate chapel and the Institute of Dairy Science. Cork city has the Crawford school of art with public galleries of paintings and sculptures. The city museum was established in the garden of Fitzgerald park.

Cork harbour, behind a narrow entrance sheltered by islands, is considered one of the finest natural harbours in Europe. The entry is about 1 mi. wide, increasing within to about 3 mi. with a length of about 10 mi. The port of Cobh (*q.v.*) is on Great Island, at the head of the outer harbour. Direct trade to and from Cork is chiefly with ports in England, Wales and Scotland; but there is also regular trade with the Netherlands, France, Scandinavia, Spain and other European countries. Imports include wheat and maize (corn), timber and building requisites and raw materials. Exports are chiefly of cattle, provisions, butter and fish. The Cork butter market has been famous since the early 17th century. The present market was built in 1769.

Established industries include distilleries, breweries, tanneries, iron foundries; the manufacture of woolen and leather goods, tweeds, gloves, hats and chemical fertilizers, and bacon curing. During World War I, Henry Ford, who had family connections in

County Cork, built on the disused racecourse his first factory in Europe for producing agricultural tractors. His enterprise gave rise to a new industrial area in Cork, which includes the principal rubber factory in Ireland, grain silos and oil storage depots and an electric power station. Other flourishing industries, including nylons, carpets, tiles and paints, have arisen on the western and southern outskirts of the city. (D. G.)

**CORK.** Cork consists of the irregular-shaped, thin-walled, waxy-coated (suberized) cells that make up the bark of many trees. Although the winged ridges along a hackberry trunk or the peeling bark of the birch are by this definition cork, in its restricted commercial sense only bark of the cork oak (*Quercus suber* and its varieties) merits the designation. Small amounts of commercial cork are harvested in Brazil from the "Pau Santo," *Kielmeyera coriacea*, and a little in Japan from a native oak, *Quercus variabilis*.

**Distribution.**—The cork oak is native to the Mediterranean region, where it grows abundantly in Portugal, Spain, parts of southern France and Italy, and in north Africa. Spain alone has over 2,000,000 ac. of cork forest. It has been introduced into the southern United States, the more important plantings being in California. Trees scarcely yield significantly for at least 20 years, and at 50 years produce only about 100 lb., as compared with 500 lb. or more for octogenarians. Hence it is not surprising that chief production comes from extensive natural and a few cultivated stands in southern Europe and north Africa.

In general, continued exploitation, and some use for wood and charcoal, with only little reforestation, has gradually diminished stands and supply. The custom of letting hogs and cattle run in the cork forest, to feed on acorns, plus in many cases cultivation between trees, tends to prevent establishment of new seedlings. World production averages close to 300,000 tons annually, some 50% or 60% exported to the U.S.

**Description and Properties.**—The inner bark of the cork oak develops an especially uniform and continuous regenerative tissue. After the outer bark is peeled this tissue proliferates sufficient cork cells to the outside that, in a healthy tree, one to two inches of a uniform new cork sheathing (new bark) forms anew in from three to ten years. Stripping this regenerated layer yields commercial cork slabs. The original bark or first stripping is rough and uneven, fit only for grinding. Even the second stripping may not be top quality, with third and subsequent strippings producing cork fit for bottle stoppers.

The uniqueness of cork stems from the impervious air-filled cells, as much as 35% fatty acid; each is a watertight, flexible compartment. En masse they are a remarkably effective insulating medium, impervious to liquids. This is undoubtedly an adaptive response to the harsh natural environment, where the cork oak trunk needs protection from heat and drying winds in summer.

When cork is cut, the cut surface presents a myriad of closely packed half spheres each analogous to a rubber suction disk such as is often used to hold against glass or other smooth surfaces. Wet or dry, clean or greasy, these miniature suction cups adhere upon slight pressure. This attribute, combined with excellent insulating and wear-resistant qualities, makes cork a favourite medium for nonslip handles, catwalk flooring, bobbins and rollers. Constructed as it is of thin-walled cells forming a matrix of air pockets, it is among the lighter substances in weight, only one-fifth as heavy as water.

An obvious use is for floats, indeed reportedly used by the Romans as early as the 1st century. Life preservers of cork were an almost inevitable adaptation of a later age. Since the tiny cells act like balloons, compressing with pressure, then expanding back to original size upon release, cork shows excellent resiliency without set. It has been extensively used to cushion heavy machinery, and for gaskets sealing machine parts and pipe joinings.

Cork cells are chemically inert, deteriorated little or not at all by the weaker acids and bases or most organic solvents; thus cork's traditional importance as bungs and stoppers, including the familiar bottle corks. Cork suffers no breakdown with age, nor will it support combustion. It is tasteless, odourless, and of pleasant "feel" and colour.

**Harvesting.**—Regulation has been imposed upon harvest of cork in most production areas, in order to preserve and protect existing stands as much as possible. It is generally illegal to strip bark from trees of less than a prescribed diameter, or more frequently than at 8 to 11 year intervals. One tree in California, however, recouped and was ready for another stripping in three years' time. There is 3% to 5% mortality among trees at first stripping.

Stripping is done by hand, in summer, and has changed little through the ages. Girdling cuts ring the trunk or branch at convenient distances, after which a longitudinal slit is made with a specially designed ax or curved saw. Starting at this cut the outer bark is carefully pried loose from the inner tissues, and peeled away with the help of various levers and wedges. Care is taken not to injure the deeper regenerative layer (cork cambium); otherwise new cork will be warty and of little value. Strippers can harvest 1,200 lb. in a day.

The removed peel is usually like a hollow cylinder cleft on one side. It is traditionally steamed or boiled and pressed flat, although experiments in California have shown that the boiling step is not really necessary. Boiling or steaming removes soluble tannins, while the rough "woody" surface is scraped clean by hand.

**Marketing and Uses.**—In Algeria, one of the leading cork producers, cork auctions proceed much as with tobacco in the United States, a novel twist being that prices start at the "top" and come progressively downward until a bid is made. A buyer must anticipate when a competitor is likely to bid, while maintaining an unrevealing stoic attitude himself.

Whether purchased at auction or under contract, cork is usually shipped without further processing to industrial centres throughout the world. There superior sheets may be used for stamping out bottle corks, always cut in the long direction, from the end rather than across the sheet, so that the natural pores (lenticels of bark) run crossways, not through the closure (which might permit some leakage).

The bottle stopper has long been the most familiar use of cork. Its biggest modern uses include insulating sheet and floor coverings. Insulating sheet and cork "board" may be made by compressing ground cork or cork trimmings at elevated temperatures, or mixing it with adhesive binders. Linoleum utilizes pulverized cork flour mixed with drying oils, which is bound to a burlap backing.

Essentially a mass of air bubbles, cork has excellent insulating and soundproofing qualities, for such uses as refrigeration chambers; with suitable binder cork makes an attractive and resilient floor and wall tile. Colour and texture make it appropriate for decorative purposes. Other familiar uses are for gaskets, floats, handles, beverage cap liners, buffers and various small pads as insulators.

(R. W. Sv.)

**CORK AND ORRERY, MARY MONCKTON, Countess of (1746-1840)**, whose witty conversation and infectious enthusiasm made first her mother's house and later her own a meeting place for the great men of the day, was born on May 21, 1746, daughter of the 1st Viscount Galway. Samuel Johnson, Sheridan, Joshua Reynolds, Edmund Burke and Horace Walpole constantly visited her at her mother's London house, and Mrs. Siddons was her closest friend.

In 1786 she married Edmund Boyle, 7th earl of Cork and Orrery (d. 1798), and continued to hold "conversation parties" at which Canning and Castlereagh, Lord Byron, Sir Walter Scott, Lord John Russell, Sir Robert Peel, Theodore Hook and Sydney Smith were regular guests. She is supposed to have been the original of Lady Bellair in Benjamin Disraeli's *Henrietta Temple* (1837) and of Mrs. Leo Hunter in Charles Dickens' *Pickwick Papers* (1837).

She died in London on May 30, 1840.

**CORKSCREW**, an instrument for boring into a cork and extracting it from a bottle on exertion of a pull, which is found in many forms throughout the world. Corkscrews have an endless variety in screw shapes and handle styles.

Studies in the U.S. indicated that relatively few corkscrews could be relied upon invariably to remove tightly seated corks

THREE CORKSCREW SHAPES (A) AUGER TYPE WITH METAL CORE. (B) WIRE TYPE, BENT AROUND HOLLOW CENTRE; (C) WEB TYPE

from wine bottles. The Wine Institute, in California, variously tested 23 corkscrews and the best specimens were found to have more than twice the gripping power of the poorest. It was recommended that a corkscrew be long enough to penetrate fully through a long wine cork and also to provide a lifting surface below it; that the point be so situated as to make a path through the cork that the centre of the threads would follow; that the distance between threads be uniform; that the edges of threads be not sharp. Best results were observed with corkscrews having a diameter of .35 in. or slightly more, a distance between threads (measured along the axis) of .40 in. and a point tapered down for a distance (measured along the axis) of not more than .40 in.

Screws formed by rigid wire spirals performed at least as well as the steel-web types; auger types with thick central shafts, which apparently weakened the cork centres, pulled out through the corks too easily. The tests showed that it was sometimes necessary to exert as much as 300 lb. of force to extract a cork from a wine bottle in a straight pull, and that therefore a leverage device was desirable. Leverage devices recommended were those that drew the cork without the need of a continued turning of the screw.

The kind most popular with restaurant and hotel personnel was a folding jackknife or boot-lever type equipped with a binged boot, which stood on the bottle rim and provided a fulcrum while the other end of the lever was pulled upward. (L. B. L.; X.)

**CORKWOOD**, the name given to several tropical American trees and shrubs with light porous wood, especially to the alligator apple or pond apple (*Annona glabra*), found in the Everglades of Florida and widely in the tropics; the magaguabush (*Hibiscus tiliaceus*) of the Florida keys, the West Indies and other warm regions; and the balsa (*Ochroma lagopus*), widespread in tropical America. The North American corkwood (*Leitneria floridana*), a small tree with pale-yellow wood, is confined to semitropical swamps in Florida and Texas and to muddy sloughs in southeastern Missouri. In New South Wales, Austr., a tree, *Duboisia myoporoides*, of the nightshade family (Solanaceae) is called corkwood. The buoyant wood of these trees is utilized for floats and numerous other purposes, especially that of the balsa (q.v.).

**CORMORANT**, a long-billed sea bird, larger than the duck, of the genus *Phalacrocorax* and the family Phalacrocoracidae. The cormorant (*P. carbo*) and its subspecies are distributed throughout the world. They frequent rocky ledges of cliffs along sea coasts, estuaries and coastal lakes and sometimes inhabit inland lake islands and trees. The cliff nests consist of a large mass of seaweed and guano, and the tree nests consist of twigs.

The eggs, from four to six in number, are small and have a thick, soft, calcareous shell, bluish white when first laid, but soon becoming discoloured. The young are hatched blind and covered with an inky black skin. As squabs they are highly esteemed for food by the northern islanders of Europe. Their first plumage is of a sombre brownish black above and more or less white beneath. They take two or three years to assume the fully adult dress, which is deep black, glossed above with bronze, and variegated in the breeding season with white on the cheeks and flanks besides being adorned by filamentary feathers on the head and a bright yellow gape. The brilliant gape is displayed in courtship. The flesh of the adult is uneatable.

Taken from the nest, this bird is easily tamed and can be trained to fish for its keeper, as was in former times commonly done in England, where the master of the cormorants was one of the officers of the royal household. The practice is obsolete in Europe, though still common in China and other areas of the far east, where

cormorant fishing is done at night, the scene being lighted by colourful torches. A strap is fastened round the bird's neck so as, without impeding its breath, to prevent its swallowing its catch. The activity the bird displays under water is almost incredible. Being propelled chiefly by its webbed feet, the cormorant wheels and turns with ease in pursuit of its prey.

Nearly allied to the cormorant, and having much the same habits, is the shag or green cormorant (*P. aristotelis*). The shag is about one-fourth smaller, is much more glossy in plumage, and its nuptial embellishment is a nodding plume. Its tail feathers number 12 instead of 14. In the south of Europe a much smaller species (*P. pygmaeus*) is found. This is a fresh-water bird. Further species, to the number of more than 30, have been recorded from other parts of the world, but all have a great similarity; New Zealand and the west coast of northern America are particularly rich, and the species found there are the most beautifully decorated of any.

All are remarkable for their curiously formed feet with all four toes connected by a web, for their long, stiff tails and for the absence in the adult of any exterior nostrils. Their voracity is proverbial; when gorged they are fond of sitting on an elevated perch, with partially extended wings. In this attitude they will remain motionless for a considerable time.

Besides the common cormorant, the crested cormorant (*P. auritus*) is found in the eastern United States, with a more southerly distribution. Brandt's cormorant (*P. penicillatus*) inhabits the North Pacific; the pelagic cormorant (*P. pelagicus*), the North Pacific and the coasts to western Mexico. The white-breasted guanay or Peruvian cormorant (*P. bougainvillei*) is one of the chief producers of guano fertilizer (see GUANO; PERU).

**CORN (MAIZE OR INDIAN CORN [*Zea mays*]).** The word "corn," originally meaning a small, hard particle or grain as of sand, gunpowder, or salt (for example: "corned" beef, i.e., preserved by salting), came to be applied to the small, hard seed of plants. In agriculture it generally referred to the seed of the cereal plants; e.g., corn laws.

Corn is often locally understood to mean that kind of cereal which is the leading crop of the district; thus, in England it refers to wheat, in Scotland and Ireland to oats. "Corn in Egypt," a world-wide expression for plenty, when first used probably meant wheat, but may have meant barley as well, these being the only two cereals in cultivation in contemporary civilizations. Maize, the principal cereal of the new world, was first known as "Indian corn" and later as "corn."

This article discusses corn in terms of its history, botany and types, the development of hybrid corn, and distribution, uses and production. For information on various insects and other pests that may damage corn see CORN BORER; ENTOMOLOGY: Principles of Insect Control; FUNGI; SMUT AND BUNT.

**Origin and History.**—Corn, a plant of the tribe Maydeae of the grass family (Gramineae) is undoubtedly a plant of American origin, since there is no evidence of any kind—archaeological, linguistic, pictorial or historical—of the existence of corn in any part of the old world before 1492. In contrast, cobs and ears of corn, as well as funerary vases and other objects ornamented with figures of corn are frequently encountered among archaeological remains in both North and South America.

Through an ingenious method developed by W. F. Libby of The University of Chicago, it became possible to estimate the age of ancient vegetal remains by measuring the decay of radioactive carbon which the original plants had absorbed from the atmosphere (see RADIOCARBON DATING). Such measurements showed

ALLAN D. CRUICKSHANK FROM NATIONAL AUDUBON SOCIETY

A NORTH AMERICAN CORMORANT  
(*PHALACROCORAX AURITUS*)

that the oldest corn found in South America by the middle of the 20th century went back to about 1000 B.C. and the oldest in North America to at least 2000 B.C. Wild corn probably occurred much earlier than this, for E. S. Barghoorn of Harvard university, in 1954, identified fossil pollen grains of corn in a drill core taken from a depth of more than 200 ft. below the present site of Mexico City.

The modern history of corn begins Nov. 5, 1492, when two Spaniards whom Christopher Columbus had delegated to explore the interior of Cuba returned with a report of "a sort of grain they call maize which was well tasted, bak'd, dry'd and made into flour." Later explorers to the new world found corn being grown by the Indians in all parts of America where agriculture was practised from Canada to Chile. The seminomadic hunting and fishing Indians in both North and South America augmented their diet of fish and game with corn from cultivated fields. The more advanced mound builders of the Mississippi valley and the cliff dwellers of the southwest were corn-growing and corn-eating people. The highly civilized Maya of Central America, the warlike and energetic Aztecs of Mexico and the fabulous Incas of Peru and Bolivia all looked to corn for their daily bread. The abundant harvest that this cereal yielded gave these ancient people leisure for weaving beautiful fabrics, molding exquisite pottery, building magnificent highways and towering pyramids, inventing a system of arithmetic and perfecting a calendar more accurate than the old world calendar for the same period. Corn was indeed "the grain that built a hemisphere."

**Spread of a Cultural Complex.**—Later corn became the bridge over which European civilization traveled to a foothold in the new world. To many of the early colonists, who learned its culture from the Indians, it became the daily bread by which they were nourished. Modern American corn growing is founded to a large extent upon an elaborate cultural complex taken from the American Indians, for not only did the European colonist adopt the corn plant but he also embraced the methods of culture, harvesting and utilization which the Indian had developed through generations of trial and error.

The planting of corn in hills, its interplanting with beans and squashes, the use of husking pegs in harvesting, the storing of the ears in ventilated cribs, the use of green corn for roasting ears, the removal of the hull with lye to make hominy are only a part of the Indian inventions adopted with slight changes by the settlers.

Introduced into Europe by Columbus and into Africa by the Portuguese, corn spread rapidly throughout the old world. Within one generation after the discovery of the new world it was known over most of Europe. Within two generations it had spread through Africa, India, Tibet and China, and when European ships began to reach the Chinese coast corn was already being extensively grown there and was being taxed by the emperor.

The first references to corn in literature appear early in the 16th century. The first botanical illustration of the plant occurs in the herbal of Leonard Fuchs, in 1542. The earliest Chinese illustration is found in the *Pen Ts'ao Kang Mu* of Li Shih-chen, which is dated at 1578. Of all the manifold products of the new world, corn spread the most rapidly, even more rapidly than tobacco.

**Botanical Origin.**—The botanical origin of corn is less clear than its geographical origin. Earlier botanists were virtually unanimous in the opinion that corn had originated from pod corn, a primitive type in which the grains are enclosed individually in chaff. A second principal theory has corn originating from a plant called by the Aztecs *teocentli*, now anglicized to teosinte.

Teosinte is undoubtedly the closest wild relative of cultivated maize. Like corn it has tassels and ears borne separately, although its "ears" contain only five or six seeds, each enclosed in a hard bony shell—characteristics that make teosinte a most unpromising food plant. Also like corn, it has 10 chromosomes, the bearers of heredity, indicating that it is a closely related species. Teosinte can readily be crossed with corn to produce hybrids that are completely fertile or almost so. Still another theory postulates that corn, teosinte and *Tripsacum*, a third American genus of the tribe

to which maize belongs, have originated along independent and diverging lines of descent from a remote common ancestor now extinct.

After 1940 evidence from genetic experiments and archaeological remains accumulated to show that none of these theories was completely correct and none wholly wrong. Archaeological specimens of corn in the early stages of domestication, discovered in Bat Cave in New Mexico in 1948 by Herbert Dick of the Peabody museum of Harvard university, proved that the ancestor of corn was not teosinte but a form of pod corn. The small cobs of this corn, scarcely longer than the diameter of a one-cent piece, once bore about 50 tiny kernels partly enclosed in chaff. Teosinte, however, played an important role in the evolution of corn under domestication, for genetic experiments demonstrated that characteristics of teosinte can be introduced into corn through hybridization, and archaeological material from other caves in New Mexico and Arizona showed that sometime in its history corn hybridized with teosinte to produce radically new types which comprise the majority of modern corn varieties of North America.

When crossed with corn, teosinte contributed to the progeny some of its own hardness and toughness and provided the strength necessary for the evolution of greatly enlarged ears.

**Botanical Characteristics.**—The corn plant is a tall, annual, grass with a stout, erect, solid stem, a fibrous root system, large narrow leaves with wavy margins, spaced alternately on opposite sides of the stem, and male and female flowers borne on separate inflorescences (fig. 1).

The male or staminate flowers are borne on the tassel which terminates the main axis of the stem (fig. 1[C]). As in all grasses, the flowers occur in small clusters called spikelets, usually arranged in pairs, one borne on a short stem, the other not (fig. 1[D]). Each floret contains three anthers (fig. 1[D]); each anther, approximately 2,500 pollen grains. A single tassel may shed several million pollen grains. These are barely visible to the naked eye, approximately 1/250 inch in length and are ovoid in shape. They are light and easily carried by the wind and this accounts for the fact that corn is naturally cross-pollinated.

The female or pistillate inflorescence, which when mature is called the "ear," is a unique structure among the grasses. Botanically, it is a spike with a thickened axis, the "cob," on which the paired spikelets are borne in longitudinal rows. Each row of paired spikelets normally gives rise to two rows of grain; hence the number of rows of grain on the ear is always an even number: 8, 10, 12 and higher, up to 36.

The pistillate inflorescence is enclosed by "shucks" or "husks" which are modified leaves (fig. 1[B]). The familiar "silks" which

emerge in a pendulous mass from the end of the ear shoot are the styles attached to the ovaries (fig. 1[E]). There is a single silk for each potential seed, and the number of seeds on the ear may equal but can never exceed the number of silks which have emerged. Pollination occurs when wind-borne pollen falling upon the fine hairs of the silks germinates and sends its pollen tube down the tissues of the long styles.

**Principal Types.**—The diversity in corn is enormous and probably exceeds that of any other cultivated plant. There are early maturing varieties, Gaspé Flint from the Gaspé peninsula of Canada and Cinquantino from the Pyrenees mountains of Spain, which mature in 60–70 days; there are very late varieties in Colombia which require 11 months to reach maturity.

The number of leaves on a single plant varies from 8 to 48; the number of tillers or suckers from none to 12. The height of the stalk may vary from less than 2 ft. to more than 20 ft. The number of rows of grain on the ear may range from 4 to 36, and the size of the ear varies from the diminutive ears of popcorn varieties, some of which are smaller than a man's thumb, to the gigantic corn grown in the Jala valley of Mexico which produces ears up to 2 ft. in length.

Accompanying the variation in vegetative characteristics is a corresponding array of distinct colours. Stalks, leaves and husks may be green, red, purple, brown, golden or striped. The silks may be green, salmon or various shades of red. The grain may be yellow, white, various shades of red, blue and brown or variegated.

Because of the great diversity of form and colour, the botanical classification of corn has presented unusual difficulties to the systematist. But beginning in 1951 substantial progress has been made in classifying the corn of the world into races which correspond approximately to breeds of livestock. Thirty more or less distinct races were recognized in Mexico, approximately the same number in Peru, and it was estimated that there are between 100 and 150 races of corn in the world. A commercial classification of corn based largely on the texture of the kernels has long been in use and five principal types have usually been recognized (fig. 2):

1. *Dent corn* is characterized by a depression or indentation in the crown of the kernel, which may vary from a dimple to a rough crease, and which is caused by the unequal drying of the hard and soft starch of which the kernel is composed. Dent corn is the principal type grown commercially in the United States, especially in the corn belt. Although dent corn may occur in any of the known grain colours, the majority of commercial varieties are either yellow or white. Before 1920, yellow corn was preferred in the north, white corn in the south, but with the discovery that yellow corn is richer than white in carotin, a precursor of vitamin A (that is, the carotin can be converted to vitamin A in the body) and hence frequently more valuable as a feed, there was a decided trend toward yellow varieties. White dent is still preferred for many industrial purposes, especially the manufacture of hominy.

2. *Flint corn* differs from dent corn in containing little soft starch, hence it does not become indented upon drying. The early-maturing flints are extensively grown in the northern United States and Canada, since they germinate more readily in cold soils than dent corn. The tropical flints, which because their hard seeds resist damage by weevils, are the preferred type in tropical lowlands.

3. *Flour corn*, also known as "soft" or "squaw" corn, is usually similar to flint corn in vegetative characteristics, but differs from it in the texture of the kernels, which are composed largely of soft starch. Because of its soft and mealy kernels, which are easily ground or chewed, flour corn is preferred by Indian tribes wherever it can be grown. It is of little commercial importance in the United States, but is the predominating type in the Andean region of Peru, Bolivia and Ecuador, where many large-seeded varieties, some with kernels an inch in length and almost equally broad, are known.

4. *Sweet corn* is distinguished by its wrinkled, translucent seeds, a condition resulting from the fact that the sugar manufactured by the plant is not converted to starch as it is in other types. Sweet corn is used almost exclusively for human consumption as green corn or roasting ears and as canned or frozen corn.

5. *Popcorn* is actually an extreme type of flint corn, and is in-

cluded with the latter by some authorities. It is characterized by small hard kernels, completely devoid of soft starch. When heated, the moisture in the cells expands, finally causing the kernels to explode or pop. Popcorn is used extensively in the U.S. confectionery industry. Most of the commercial crop is grown in several counties in Iowa and Nebraska.

**Hybrid Corn.**—An important factor in the evolution and improvement of corn under domestication has been hybridization between distinct races. The American Indian through trade and migration created numerous opportunities for hybridization and for the development of new hybrid races. The white man continued the process, often unconsciously.

The world's most widely grown corn, the corn-belt dent of the United States, is the product of hybridization which occurred in the 19th century between the late, long-grained, many-rowed, "gourd seed" corn of Virginia carried into Ohio and Illinois and the early, eight-rowed flint corn of the northeast brought into the same region by settlers from New England.

Beginning about 1920 a new method of improving corn through hybridization (fig. 3) and the controlled utilization of hybrid vigor was widely adopted and became extremely effective. The method is based upon discoveries in genetics made by G. H. Shull of the Carnegie institution, E. M. East of Harvard university and D. F. Jones of the Connecticut Agricultural Experiment station (see PLANT BREEDING).

The first step in the production of hybrid corn is the isolation of superior inbred strains. This is accomplished by artificial self-pollination under bags, which represents a form of inbreeding approximately three times as intense as brother and sister mating in livestock. Inbreeding reduces vigour and productiveness, but results in great uniformity within the strain. The second step involves the crossing of inbred strains by pairs ( $A \times B$ ,  $C \times D$ , etc.) to produce single crosses. Single crosses are exactly as uniform as the parental inbred strains, but because of the phenomenon of hybrid vigour (see HYBRIDISM), much more productive. Single-crossed seed of sweet corn is extensively used in the production of green corn for commercial canneries where uniformity in size and shape of the ears is important. Single-crossed seed is usually too expensive, however, for general farm use. A third step is necessary to reduce seed costs. This third step, the production of double-crossed seed, involves the crossing of two single crosses ( $AB \times CD$ ). Double crosses are slightly less uniform than single crosses, but almost equally productive.

Hybrid corn does not breed true; but once a satisfactory combination of inbred strains has been identified the hybrid seed can be produced anew each year from the true-breeding parental inbred

strains. Crossing is readily accomplished by growing two stocks in alternate strips in the same field and removing all tassels from the plants of one before pollen is shed. Hybrid corn proved so productive that by the second half of the 20th century, in spite of the expense involved in producing the seed, almost 90% of the U.S. corn acreage was being planted annually to hybrid corn, and this type of corn had also become important in Italy, France, Spain and the countries of Latin America.

**World Distribution.**—Although pre-eminently an American crop, corn is one of the most widely distributed of the world's food plants. It is grown from  $58^\circ$  N. lat. in Canada and U.S.S.R. to  $40^\circ$  S. lat. in South America. It is cultivated below sea level in the Caspian plain, and at altitudes exceeding 12,000 ft. in the Peruvian Andes. It thrives almost equally well in the short summer of Canada and the perpetual summer of tropical Colombia. A crop of corn matures somewhere in the world every month of the year.

From the standpoint of acreage planted, corn ranks second among the world's crop plants, being exceeded only by wheat. In the United States, which produces more than half the world's crop, it is by all odds the most important crop, being grown in every state and on approximately three-fourths of all farms. It reaches its maximum importance in the corn belt, a region of fertile, well-drained soils comprising Iowa and parts of Illinois, Indiana, Ohio, Missouri, Kansas, Nebraska, South Dakota and Minnesota. In this feed-grains and livestock region, corn occupies approximately one-half the cultivated land.

In the corn belt a combination of fertile soils, agricultural technology, progressive farmers, and improved corn has created the most productive agricultural civilization the world has ever seen. An efficient corn-belt farmer with the help of one man can grow the corn to produce enough meat and livestock products to feed three or four hundred people in town.

Brazil ranks second and Argentina usually third to the United States in corn production. In Europe, corn is of greatest importance in the Danube basin and of considerable secondary importance in Italy, Spain and southern France. Egypt, India and South Africa produce considerable quantities of corn, largely for domestic consumption.

**Utilization of Corn.**—Corn is utilized in three principal ways: (1) as a feed for livestock; (2) as a human food; (3) as a raw material in industry.

In the United States, about 80% of the corn produced is fed to livestock; approximately half of this amount to hogs, the re-

FIG. 3.—HYBRID CORN: INBRED STRAINS A AND B ARE CROSSED TO PRODUCE A SINGLE CROSS, INBREDS C AND D ARE CROSSED TO PRODUCE A SECOND SINGLE CROSS. SINGLE CROSSES AB AND CD ARE CROSSED TO PRODUCE THE COMMERCIAL DOUBLE CROSS

mainder to beef and dairy cattle, horses and mules and poultry. It requires 10–12 lbs. of corn to produce 1 lb. of beef, 6–8 lbs. to produce 1 lb. of pork. For feeding cattle, the entire plant is frequently harvested and used as ensilage (*q.v.*), the product of bacterial fermentation.

As a human food, corn is inferior to other cereals. Its gluten is of poor quality and it makes a heavy, crumbly bread. It is deficient in niacin, and diets containing excessive amounts of corn often result in pellagra. Nevertheless, corn was used exclusively for human food in prehistoric times, and is still used extensively for this purpose in Latin-American countries, in parts of Europe and the United States and in South Africa and India. The *tortilla*, a thin flat cake of corn, is the daily bread of Mexico, and corn constitutes 75% to 85% of the diet of the Maya Indians of Guatemala.

In the United States, corn is of greatest importance as a human food in the south, but is used to some extent in all parts of the country in the form of corn bread, hominy, mush or polenta, grid-dlecakes, scrapple, popcorn, confections and numerous manufactured cereal preparations. Sweet corn, harvested when the grain is in the "milk" stage, is an important American vegetable, consumed fresh, canned or frozen.

All parts of the corn plant are used as raw materials in industry. The stalk may be manufactured into paper and wallboard. Husks are used as filling material. Cobs are used for fuel, for making charcoal and for the preparation of industrial solvents. Corn cob pipes are manufactured from a large-cobbed variety grown in Missouri. The most extensive industrial uses, however, are concerned with the grain. These consume about 9% of the annual U.S. corn crop and comprise three principal processes: wet milling, dry milling and fermentation.

In the wet milling process the grain is first soaked for 40–60 hr. in a dilute solution of sulfurous acid. Through progressive grinding and manipulation the germ and hulls are then separated from the remainder of the grain. Further treatment yields numerous products including starches, dextrins and "British gums" used in adhesives and sizing agents, syrup, dextrose, oil and gluten.

In dry milling the corn is briefly exposed to water spray or steam. This results in marked differences in the moisture content in various parts of the kernels and makes possible the physical separation of the kernel into its component parts. The principal products of dry milling are hominy, grits, meal, flour, oil and feed.

The fermentation industry first changes corn starches into sugars and then employs yeast to convert the sugars into beverage alcohol in the form of beer and bourbon whiskey or into industrial alcohol. Other microorganisms are employed to convert starches and sugars into a wide variety of chemical products.

**Production Statistics.**—The estimated average annual production of corn in the principal producing countries in the mid-1950s was as follows: United States 3,000,000,000 bu., compared with an average of 2,300,000,000 in 1935–39; Brazil 240,000,000 and 215,000,000, respectively; Argentina 190,000,000 and 300,000,000; and Mexico 140,000,000 and 68,000,000.

In the 1960s United States production exceeded 3,500,000,000 bu. annually. Production in Brazil exceeded 300,000,000; in Argentina, 200,000,000; and in Mexico increased to 250,000,000. Corn production in the U.S.S.R. averaged 170,000,000 bu. in the 1935–39 period, almost doubled with an average of 320,000,000 in 1955–59, and exceeded 400,000,000 in the 1960s. Among other leading corn producing countries in the 1960s, Rumania, Yugoslavia and South Africa each averaged more than 200,000,000 bu., and India, Italy and Hungary each averaged more than 100,000,000 bu.

**CORN (CLAVUS):** see SKIN, DISEASES OF.

**CORNACEAE**, the dogwood family of dicotyledonous plants consisting of 10–15 genera and about 100 species, in both hemispheres, some in temperate, others in tropical regions. The largest genus is *Cornus*, with about 45 species in North America, Europe and Asia. Various species are known as dogwood; the first syllable of this name, a modification of the old English *dagge*, alludes to the fact that the wood of European species was used for making skewers. Various species are cultivated for ornamental purposes, especially the Eurasian Cornelian cherry and the North American flowering dogwood. See DOGWOOD. (E. D. Ml.; X.)

**CORNARO, CATERINA** (1454–1510), queen of Cyprus was born at Venice, the daughter of Marco Cornaro, a Venetian noble, and Fiorenza, daughter of the duke of Naxos.

When King John II of Cyprus died, his succession was disputed; James de Lusignan, his natural son and a close friend of Marco's brother Andrea, seized the island and sought Venetian support for his claim to the crown, as James II, by marrying Caterina. The contract was signed in 1468. Adopted as a "daughter of the republic" by the doge and backed with the title of queen of Cyprus, Jerusalem and Armenia, Caterina, in 1472, sailed for Cyprus where the formal marriage ceremony took place.

In 1473 James died, leaving his kingdom to his queen and their unborn child. When after James III's birth the Venetian fleet sailed away a plot broke out in favour of Zaria, an illegitimate daughter of James II.

The Venetians returned and soon restored order, but began themselves to contemplate the seizure of Cyprus. Fearing an attack by Sultan Bayazid II and having discovered a conspiracy to marry Caterina to Alfonso II of Naples, Venice formally annexed Cyprus and recalled Caterina, who reluctantly abdicated in favour of the republic in 1489.

At Venice the government conferred on her for life the castle and town of Asolo, where she held court until her death on July 10, 1510.

See H. Brown, *Studies in the History of Venice*, vol. i (1907), with bibliography.

**CORN BELT**, the popular name of the area in the midwestern part of the United States in which corn (maize) and soybeans are the dominant crops. The region is one of considerable diversity, however, and an alternative name, feed-grains and livestock region, describes it more accurately. See AGRICULTURE: *United States: Corn Belt*.

**CORN BORER.** Foremost among insects attacking corn (*Zea mays*) throughout its world distribution is the European corn borer, the larval stage of a pyralid moth (*Pyrausta nubilalis*). This borer, with a wide geographic range in the northern hemisphere, occurs all over Europe as far north as latitude 58° N. It occurs also in many parts of Asia and in the south Pacific. Its climatic range varies from the dry steppes of southeastern Russia to the moist tropical conditions of Guam and the Philippines. It is known in Europe as an enemy of maize, hops, millet, hemp and many other food plants.

In the United States the European corn borer is one of the most devastating insect pests of American agriculture of record. Originally introduced into the country from Europe some time prior to 1912, it was first observed to be damaging corn in New England in 1916–17 in areas where the manufacture of brooms from broom-corn imported from Europe was a principal industry. Presumably, the broomcorn was the vehicle of importation of the borer. Since the enactment of the U.S. Plant Quarantine act of 1912, further importation of the pest has been checked. However, the borer has spread westward and southward to blanket the entire "corn belt" of the midwestern U.S. It is found in varying degrees of abundance in all states east of the Rocky mountains, except Florida. This spread is of varying magnitude from year to year, depending principally upon prevailing climatic conditions and the increase in numbers of borers that produce two or more broods in a growing season (the earlier strain of borers in the corn belt chiefly produced one generation per growing season).

Of aid in the borers' rapid spread are the strong flight capabilities of the moths; the use of more than 200 species of grains, weeds, vegetables and flowers as alternate hosts or sheltering

places; the tenacity of borer survival in corn plants; and non-occurrence of mountain barriers in the lake and plains states.

In spring full-grown, inch-long larval and pupating caterpillars, pinkish with dark heads, may be found in the stalks of the host plant. They emerge during the summer as yellowish-brown moths with a wingspread of about one inch. The female lays her eggs on the underside of the leaves (especially the lower ones) of the host plant. In about a week the eggs hatch and the tiny caterpillars feed externally on the plant. When they are half-grown, the larvae bore into the stalks and feed there until the cold weather. They overwinter as larvae.

Annual losses due to this pest in the United States range widely, but a particularly heavy infestation in 1949 was responsible for the loss of more than 315,000,000 bu. of field corn. Also considerable are the direct losses to sweet corn and other vegetables; and the associated losses due to contamination of infested canning crops, such as sweet corn and peppers, and ornamentals, particularly dahlias and gladioli. Control measures have not resolved the problem completely, but they have resulted in the ability of the U.S. farmer to live with the borer with a minimum impact on corn culture economy. The use of effective insecticides is complicated by the necessity to insure the noncontamination of food or feed crops with hazardous chemical residues. Of particular interest is the use of insect parasites of the borer, all originating from foreign sources; the development of strains of corn resistant to the borer; and the increasing promise of pathogens as practical control agents.

In addition to the European corn borer, a number of other borers are known to attack corn in the United States, although with a much more limited range of distribution. Foremost among these are the southwestern corn borer (*Zeadiatraea grandiosella*), occurring from Mississippi to Arizona and from Kansas to the Gulf of Mexico; and the sugarcane borer (*Diatraea saccharalis*), occurring on sugarcane, corn, rice, sorghums and wild grasses in the Gulf coast regions from Texas to southern Florida, and in southern Georgia. As with the European corn borer, the use of insecticides and the development of strains of corn resistant to attack by these borers afford some prospect for their control, but effective and economical measures are not currently available for general grower use. Other borers attacking corn in the United States, although of minor economic importance, are the stalk borer (*Papaipema nebris*), the southern cornstalk borer (*Diatraea crambidoides*) and the lesser cornstalk borer (*Elasmopalpus lignosellus*).

**CORN CRIB: see FARM BUILDINGS.**

**CORNEILLE, PIERRE** (1606–1684), leading French dramatic poet, the creator of French classical tragedy. He was born in Rouen on June 6, 1606, and came of a well-to-do middle-class Norman family: his grandfather, father and uncle were lawyers; another uncle and a brother took holy orders; a younger brother was a well-known poet, Thomas Corneille (q.v.). The family house, in which he lived until past 50, still stands in the rue de la Pie in Rouen. He was educated by the Jesuits in the building which still serves as the town lycée, won two prizes for Latin verse, became a licentiate in law and wrote his first play before he was 20. From 1628 to 1650 he seems to have worked as crown counsel in the local office of the department of waterways and forests, and to have spent increasing leisure on writing plays. He said of his *Mélite* (performed 1629; publication, as usual with his plays, a year later) that its success surprised him and established a new company of actors in Paris. For about six years he wrote comedies: *Clitandre* (1631), *La Veuve* and *La Galerie du palais* (1632), *La Suivante* and *La Place royale* (1634), *La Comé-*

*die des Tuileries* and *L'Illusion comique* (1635). Noticed by Richelieu, who attached him to his team of authors, Corneille seems to have enjoyed a cardinal's pension of 1,500 livres. After the success of Jean de Mairet's *Sophonisbe* in 1634 he wrote a tragedy, *Médée* (1635), but he returned to experiment with a tragicomedy which has proved his most famous play. It is an odd fact that the date of first performance of *Le Cid* cannot be fixed; early in 1637 seems most probable. The famous "Querelle," or quarrel, which followed is now thought to be due not so much to the novelty of the play as to the author's demand for an increased share of the takings and to his tactless poem, *Excuse à Ariste* (1637). After hard-hitting pamphlets on both sides, Richelieu seems to have ordered the closure with the appearance of the *Sentiments de l'Académie française sur le Cid* in Dec. 1637. The lapse of three years before Corneille's next play, the famous tragedy *Horace* (1640), has been explained partly as pique, partly by a lawsuit disputing the creation of a second legal office on a par with his own. He continued to write tragedies: *Cinna* (1641), *Polyeucte* (1643), *Pompée* (1644), *Rodogune* (1645), *Théodore* (1646), *Héraclius* (1647). In 1639 he produced a successful comedy, *Le Menteur*, and a first collected edition of plays. As soon as the troubles of the Fronde permitted, he started again with *Andromède* (1650), a play in which stage machinery was very important, and *Don Sanche d'Aragon* (1649), which he called a *comédie héroïque*. This last play, like *Clitandre*, had clear political allusions, as had the next, *Nicomède* (1651). In the next year a tragedy, *Pertharite*, seems to have had a poor reception, and for the next eight years his only writing was a translation of the *Imitatio Christi* (4 parts, 1652–56). He returned to the theatre, apparently on Nicolas Fouquet's invitation, with an *Oedipe* in 1659 and another collected edition in 1660, prefaced by three essays on dramatic theory, and for the next 14 years produced almost a play a year: *La Toison d'or* (1661), *Sertorius* (1662), *Sophonisbe* (1663), *Othon* (1664), *Agésilas* (1666), *Attila* (1667), *Tite et Bérénice* (1670), *Psyché* (in collaboration with Molière and Philippe Quinault, 1671), *Pulchérie* (1672), *Suréna* (1674).

Thus for nearly 40 years in all—continuously for 20 years from 1630 and for nearly 15 years after 1660—this astonishing production of elegant drama had provided the main entertainment of the French court and of the Parisian middle class and in so doing had created a new art form, with a European reputation (of which Dryden's *Essay of Dramatick Poesy*, 1665, is but one witness) and had won for its author an immense personal prestige. If modern research shows Corneille as grasping in the "Querelle" and ungenerous toward his younger rival, it should be remembered that the whole story is not known and that what is known is insignificant beside the fact that he perfected and created a dramatic instrument which could be used, ready-made so to speak, by one of the great tragic poets of modern times, Jean Racine (q.v.). Corneille died in Paris, Oct. 1, 1684.

Corneille's theory of drama, as found in the essays of 1660, is disappointing, since it gives contemporary polemic rather than his own real principles. But it is fairly clear from his practice what those principles were. Time after time he would take a subject which would provide him with a minimum of physical action and almost a maximum of moral or mental conflict. These subjects he found chiefly in Roman and Byzantine history (which was not so unknown to his public as to most modern persons, as the history taught in French schools in his day was ancient history, not French history). All his plays move around a single central crucial point, usually of rivalry in love or war. In all of them the action is conveyed within a strict form; nothing is left to music or physical action, everything is said, elegantly, rhetorically, in the grand style and in Alexandrine verse. This last feature is used with amazing dexterity as an instrument to convey all shades of expression: irony, anger, soliloquy, repartee, epigram. Such a play as *Polyeucte* has lovely lines ("Honteux attachements de la chair et du monde . . .") and equally impressive stichomythy: "Imaginations.—Célestes vérités.—Étrange aveuglement.—Éternelles clartés . . ." which convey a clash, not so much between actors as between concepts. Action in this drama is reaction. It

concerns not what is done, but what is resolved, felt, suffered. Its formal principle might be said to be symmetry: presentation, by a poet who was also a lawyer, of one side of the case, then of the other, of one position followed by its opposite. In play after play Corneille uses a dramatic situation leading to a discussion of controversial issues; and it was more than anything else perhaps the skill with which he gave expression to contemporary problems that made so many of his hearers think with Saint-Évremond that "dans la tragédie Corneille ne souffre point d'égal" ("in tragedy Corneille has no equal") and with Voltaire that he was called "le grand Corneille" not so much to distinguish him from his brother as from all other men.

Seen from a 20th-century vantage point he appears as a master of drama rather than in particular of tragedy. He excels in showing personal and moral forces in conflict rather than in calling up visions of the limits of human endurance. Only in one or two of his masterpieces can he be said to have evoked the real atmosphere of tragedy. But his greater plays are so famous with his own people that some account of their themes should be given here.

*Le Cid* has been called an exciting overture to his work, but it is classical in that it presents not the adventures of the young Cid as in the Spanish source but a single situation created by the young man's duty to avenge his father against an insult by the father of his beloved Chimène. Hence the "wit," in the 17th-century sense, in lines that point the claims of honour and of love. Rodrigue kills Chimène's father; Chimène demands his life in return. The paradox of pursuing what one loves best is put in lines that have not yet lost their hold on French audiences.

*Horace* presents the combat of the Horatii and the Curiatii as told by Livy (book i, ch. 24) but without the combat. The champions are reduced from six to two, and the father and two women are included to allow a sort of crescendo of possible reactions to war. After the patriot has murdered his pacifist sister, the whole case is argued before the king. Voltaire said that never before had convictions been expressed with such sublimity on the stage.

*Cinna* has been called Corneille's most perfect dramatic machine; it centres around a conspiracy against Augustus. Cinna himself is a reluctant conspirator, dominated by his violent lover Émilie who is seeking revenge for a murdered father. Augustus checkmates the plotters by granting a political pardon instead of violence. The boast of the emperor that he is strong enough to be merciful ("Je suis maître de moi comme de l'univers") is a dramatic climax rather than a clue to Corneille's view of character.

In *Polyeucte* the Christian convert welcomes a martyr's death ("Je consens ou plutôt j'aspire à ma ruine") but his wife Pauline, pressed by a former pagan lover Sévère, insists that marriage makes claims as important as those of religion. The two are as irreconcilable as patriotism and pacifism, and the fanatical Polyeucte echoes the fanatical Horace: "Je ne vous connais plus si vous n'êtes chrétienne."

*Rodogune* shows the steps whereby ambition brings Cléopâtre to crime. She poisons all rival claimants to power and finally herself: "Je t'ai défait d'un père, et d'un frère, et de moi." Corneille's favourite play, it became a storm centre in the 18th century and was attacked by Lessing, who tried to show that its counterpart, Shakespeare's *Richard III*, was morally less objectionable.

In *Nicomède*, a drama of dynastic succession, the forthright prince Nicomède fights for the throne and the lady against his weak father Prusias, a mother-in-law and a half-brother. These contrasts have certain features of comedy and the play was acted by Molière. In 1959 it was thought to suggest the atmosphere of the German occupation, as in 1651 it had been taken as referring to Louis II de Bourbon, prince of Condé.

**CORNEILLE, THOMAS** (1625–1709), French dramatist, was born at Rouen on Aug. 20, 1625, being nearly 20 years younger than his famous brother, with whom he was always and inevitably compared. For over 40 years he was one of the most prolific and practised artisans of the French theatre, constantly experimenting and showing great knowledge of public taste. His first plays were comedies, in many cases adaptations from Calderón (q.v.) or Francisco de Rojas Zorrilla (*Les Engagements du hazard*, 1649, *Le Feint Astrologue*, 1650, *Dom Bertran de Cigarral* and *L'Amour à la mode*, 1651, *Les Illustres Ennemis* and *Le Geolier de soy même*, 1655–56, and *Le Charme de la voix*, 1656–57). In 1653 he adapted the novel *Le Berger extravagant* (1627) by Charles Sorel (q.v.) as a "pastorale burlesque" and scored his first big success with a tragedy, *Timocrate*, in 1656, the subject of which was taken from La Calprenède. Until 1674 he produced a tragedy nearly every year, including his most famous play *Ariane* (1672), which Mme de Sévigné went to see for the acting of La Champmeslé. His chief success in comedy was probably *Le Baron d'Albikrach* (1688). After 1674 he experimented with plays and operas with much stage machinery, in collaboration with Donneau de Visé, Bernard de Fontenelle and Jean-Baptiste Lulli himself. He wrote for all the theatres of Paris: *Timocrate* for the Marais, *Dom Bertran* for Molière's company at the Palais Royal, *Ariane* and *Le Comte d'Essex* (1678) for the Hôtel de Bourgogne, *Circé* (1675) and *La Devineresse* (1679) for the Guenegaud, *L'Usurier* (1685) for the Comédie Française. His technique was admired by Philippe Destouches (q.v.). He died ("pauvre comme Job," says a correspondent) at Les Andelys (Eure) on Dec. 8, 1709.

**BIBLIOGRAPHY.**—G. Reynier, *Thomas Corneille, sa vie et son théâtre* (1892); for revised dating of plays see H. C. Lancaster, *History of French Dramatic Literature in the XVIIth Century*, part 2, vol. ii, pp. 748–761 (1932). There is a critical ed. of *Le Berger extravagant* by F. Bar (1960). (W. G. Me.)

**CORNELIA** (2nd century B.C.), second daughter of Scipio Africanus the elder, mother of Tiberius and Gaius Sempronius Gracchus (q.v.) and of Sempronia, wife of Scipio Aemilianus Africanus the younger. On the death of her husband, Tiberius Sempronius Gracchus (154 B.C.), by whom she had 12 children she remained unmarried, even refusing the hand of Ptolemy VIII Euergetes of Egypt. She gave her time to the education of her surviving sons, Tiberius (163–133) and Gaius (154–121), to whom she was devoted: when asked to show her jewels she presented her sons. Although hostile propaganda later suggested that she had encouraged her sons' more revolutionary policy, she seems rather to have restrained them. After Gaius' murder (121) she retired to Misenum (Miseno), where she devoted herself to Greek and Latin literature. She was highly educated, and her letters were celebrated for their beauty of style. Reputed fragments of them preserved in the manuscripts of Cornelius Nepos (1st century B.C.) may not be genuine. (H. H. Sp.)

**CORNELIUS, SAINT** (d. 253), pope from 251 to 253, was elected during the lull in the persecution by the emperor Decius. In 253, under the emperor Gallus, he was exiled to Centumcellae (Civitavecchia), where he died in the same year. Several of his letters, including some to his friend St. Cyprian, survive. His feast is kept with that of St. Cyprian, on Sept. 16.

**CORNELIUS, PETER** (1824–1874), German composer and author best-known for his opera *The Barber of Bagdad*, was born at Mainz on Dec. 24, 1824. The son of an actor and actress, he played in the theatre himself in his youth, at Mainz and at Wiesbaden. In 1844 he studied composition with Siegfried Dehn and was later music critic for two Berlin journals. From 1853 to 1858 he lived at Weimar in the circle of Liszt and the Princess Sayn-Wittgenstein and translated articles by Berlioz and Liszt for the *Neue Zeitschrift für Musik*. In 1857 he began his comic opera *Der Barbier von Bagdad*, on a libretto of his own based on *A Thousand and One Nights*, which was conducted by Liszt at Weim-

mar the following year. The opera was a failure and led to Liszt's resignation from the Weimar opera. It was successfully revived in a reorchestrated version by Felix Mottl after the composer's death. From 1859 to 1864 Cornelius lived in Vienna where he became a friend of Wagner. His opera *Der Cid*, on a libretto adapted by Cornelius from the play by Corneille, was successfully produced at Weimar in 1865. In the same year he accompanied Wagner to Munich where he was reader to Ludwig II and professor at the royal school of music. His last opera *Guntöd* (libretto adapted from the *Edda*) was completed by C. Hoffbauer and E. Lassen and produced at Weimar in 1891. He died at Mainz on Oct. 26, 1874.

A versatile and sensitive musician, Cornelius hardly fulfilled his original gifts, among them a gift for writing lyric poetry. He wrote many settings of his own poems, notably the *Weihnachtslieder*, which includes the well-known "Three Kings From Persian Lands Afar," and the *Brautlieder*, and of poems by Heine, Hölderlin and Annette von Droste-Hülshoff. Among his posthumously published works revealing his lyrical gifts is *Die Vätergruft* for baritone and orchestra. Cornelius' *Literarische Werke* were published in four volumes (1904-05) and his *Ausgewählte Schriften und Briefe* were edited by P. Egert (1938).

**BIBLIOGRAPHY.**—C. M. Cornelius, *Peter Cornelius*, 2 vol. (1925); A. E. Cherbuliez, *Peter Cornelius* (1925); H. Pricken, *Peter Cornelius als Dichter und Musiker* (1951).

**CORNELIUS, PETER VON** (1783-1867), German painter notable for his part in the revival of fresco painting, was born in Düsseldorf on Sept. 23 (?), 1783. His early works are unremarkable examples of the neoclassicism current in German academies during his youth, but his style gradually changed after his meeting in 1803 with the brothers S. and M. Boisserée—collectors of German Gothic art—and under the influence of the romantic authors W. H. Wackenroder, Ludwig Tieck and A. W. Schlegel. More important still were Dürer's marginal drawings for the prayer book of the emperor Maximilian, published in lithographic facsimile in 1808. Hence in his illustrations to Goethe's *Faust* (1816) Cornelius retains from the days of his academic training an insistence on line and clear design, while introducing medieval subject matter and imitating the idiom of Dürer's graphic art.

In 1811 Cornelius went to Rome where he joined a group of young German painters, the "Lukasbrüder" or "Nazarenes," led by Franz Pforr and J. F. Overbeck. Their intentions were antiacademic; they wished to create a monumental religious art, based on the study of Italian and Flemish primitives, on Dürer and the early Raphael, and they expressed these ideals in the biblical frescoes painted in the house of the Prussian consul J. S. Bartholdy. In 1819 Cornelius was invited to Munich by the Bavarian crown prince, later King Ludwig I. For his first task, the new museum of classical sculpture (Glyptothek), Cornelius himself suggested a series of frescoes from Greek mythology which were to be understood as allegories of nature and of man's strife and passions. By now his style had come under the influence of Raphael's later works in the Stanze of the Vatican and his approach was governed by Friedrich Schelling's aesthetics: painting was to give form to metaphysical ideas. During this period Cornelius was also head of the Düsseldorf academy but resigned on becoming director of the Munich academy in 1825. Between 1829 and 1840 he and his pupils decorated the new Ludwigskirche in Munich. "The Last Judgment," filling the whole east wall, is his most remarkable design for clarity and didactic purpose. He wished to embody here the essence of a Christianity freed from all sectarian bias. Hence his picture is a lesson in theology rather than a dramatic event, like Michelangelo's.

In 1841 Cornelius was called to Berlin by Frederick William IV, whose first commission was a christening present for the prince of Wales. Cornelius designed a large decorative metal shield, embodying the basic tenets of the Christian faith, with allusions to the happy event: the king of Prussia as godfather is received on the shore of England by St. George, Prince Albert and the duke of Wellington. Cornelius' main occupation in Berlin was the planning of a vast cycle of frescoes (never executed) to decorate the walls of a cemetery, modeled on the Campo Santo in Pisa,

which the king wished to build beside the Protestant cathedral.

In spite of his desire to revive fresco as a national art in order to restore painting to its rightful place in public buildings, Cornelius never developed any real sense of colour and his works look like tinted cartoons. At heart he always remained an academic artist, even if his outlook was shaped by romantic philosophy. Today we are impressed only by his penetrating intellect which gives substance to his large dogmatic pictures and order to their composition. Cornelius died in Berlin on March 6, 1867.

His influence both in Germany and abroad was considerable. When he visited London in 1841 his advice was sought for the frescoes of the houses of parliament, and his pupil J. Goetzenberger decorated Bridgewater house.

**CORNELL, EZRA** (1807-1874), U.S. businessman, a founder of the Western Union Telegraph company and a leader in the founding of Cornell university, was born at Westchester Landing, N.Y., on Jan. 11, 1807, and was educated in the public schools. In 1828 he settled at Ithaca, N.Y., where he later served as manager of flour mills. In 1842 he became associated with Samuel Morse in the early development of the electric telegraph and superintended the construction of the first telegraph line in America, opened between Baltimore, Md., and Washington, D.C., in 1844. He then became one of the most active pioneers in the establishment of telegraph lines throughout the country, in which he accumulated a substantial fortune; he was for some time the largest stockholder in the Western Union Telegraph company, organized in 1855.

Settling on a farm near Ithaca, he became especially interested in the development of agriculture. Following the passage in 1862 of the Morrill act providing national support for agricultural colleges, he took steps which led to the founding at Ithaca of Cornell university, which was formally opened in 1868. His original endowment of \$500,000, given in 1865, was increased by further personal contributions of about \$400,000 and by more than \$3,000,000 realized as profits from his operations in purchasing and allocating public lands for the benefit of the new institution, which rose to front rank among U.S. universities. He also established the Cornell library at Ithaca and built railway lines facilitating access to the town. He died in Ithaca on Dec. 9, 1874.

His son, Alonzo B. Cornell, wrote *True and Firm: A Biography of Ezra Cornell* (1884). See also the biography by Philip Dorf, *The Builder* (1952).

**CORNELL UNIVERSITY**, a U.S. institution of higher education founded under the Morrill act (see LAND-GRANT COLLEGES AND UNIVERSITIES) at Ithaca, N.Y., in 1865. See ITHACA.

**CORNER BROOK**, a city of Newfoundland, Can., is located on the west coast of the island at the head of the Bay of Islands, about 130 mi. N. of Port aux Basques; the Humber river, one of Newfoundland's best salmon rivers, flows through the city from the east. The main industry is wood pulp and newsprint, with one of the biggest paper mills in the world located there. Other industries include cement and gypsum plants. Corner Brook became a city in 1956 with the amalgamation of Town Site, Corner Brook West, Curling and Humbermouth. Newfoundland's second largest city, the population rose from 10,276 in 1951 to 26,880 in 1966. It is the site of the annual west coast agricultural and industrial fair. (R. G. HA.)

**CORNERSTONE**, a ceremonial building block, usually placed ritually in the outer wall of a building to commemorate dedication. Sometimes it is solid, with date or other inscription. More typically, it is hollowed out to contain metal receptacles for newspapers, photographs, currency, books or other documents reflecting current customs, with a view to their historical use when the building is remodeled or demolished.

Until the development of modern construction, the stone was usually at a corner, possibly as the first of the foundation stones, and a real support. From this practice arose figures of speech in many languages referring to cornerstones or foundation stones of character, faith, liberty or other excellences. Today the stone need not be a support, nor at a corner, nor even in the foundation.

Often it is placed ornamentally in the façade or in an interior wall or floor.

Early customs connected with cornerstones were related to study of the stars and their religious significance. Buildings were laid out with astronomical precision in relation to points of the compass, with emphasis on corners. Cornerstones symbolized "seeds" from which buildings would germinate and rise. Various religious rituals and Bible references spread and perpetuated the cornerstone custom. Ceremonies have been marked with processions, sacrifices, sprinklings of blood and water and wide participation by rulers, priests and other dignitaries who used the mason's trowel, often made of gold or silver. (H. B. M.; H. M.)

**CORNET**, the name of two wind instruments, one obsolete, the other modern, both sounded by lip vibration against a cup mouthpiece.

1. **CORNETT** (an old spelling that has been revived to reduce confusion with 2; Fr. *cornet[-à-bouquin]*; Ital. *cornetto*, Ger. *Zink*), a conical wooden pipe, 24 in. long, curved, with octagonal cross section and leather covering. It has fingerholes like those on a recorder, and a small cup mouthpiece of horn or ivory. With a compass of over two octaves from the G below the treble stave (staff), it was a leading wind instrument in music of many kinds over the period 1500–1670, while with trombones, to which it supplied the treble voice, it is one of the first wind instruments to be specifically scored for, by G. Gabrieli. Other sizes of cornett, the descant and the S-shaped tenor, were of smaller importance, as were also straight-built forms, including the "mute cornett" with mouthpiece cut in the head of the pipe itself. By 1700 the cornett was obsolescent, though it continued to be played locally in Germany to support choir trebles until about 1750, and with trombones in "tower music" (i.e., the religious music played in the towers of German churches) until the 1830s. Its clear tone-quality, essential for the works of Monteverdi and others, is matched by no other instrument, and its revival was tentatively begun about the middle of the 20th century.

**BIBLIOGRAPHY.**—A. Baines, *Woodwind Instruments and Their History* (1957); the article in *Grove's Dictionary of Music and Musicians*, 5th ed. (1954); F. W. Galpin, *Old English Instruments of Music* (1910).

2. **CORNET** (Fr. *cornet-à-pistons*, or *piston*), a valved brass instrument evolved in the 1820s from the continental post horn (*cornet-de-poste*, which is circular in shape like a small French horn), one of the first makers being the Parisian Halary (Jean Asté), in 1828. The tube is conical except through the three valves, tapering gently to a narrow detachable shank into which the brass mouthpiece is placed. The taper, coupled with the fairly deep mouthpiece, imparts a mellowness to the tone and a flexibility to the technique that quickly established the cornet in a leading position in brass and military bands, especially in England and America, which it retains. It is built in B flat, its music written a tone above the actual sound. Brass bands also employ an E flat soprano cornet, a fourth higher than the B flat instrument. Some older B flat cornets built for use in theatres can be changed to the key of A by turning a rotary valve.

The cornet became a popular solo instrument. Many of the earliest virtuosi were horn players and employed different crooks for different tonalities or musical moods, the longer crooks, down to E flat, giving a darker tone-quality. Celebrated Victorian soloists included Hermann Koenig and Isaac Levy. In English and American symphony orchestras cornets were frequently used for all trumpet parts, as well as for genuine cornet parts (common in French orchestration from Berlioz onward). During the 20th century, however, the revival of the trumpet ousted the cornet

from the orchestra save for parts specifically intended for it, while the use of the trumpet in modern dance music and in jazz (in which it was preceded by the cornet) has diminished the cornet's popularity as a solo instrument except with brass bands. For technique and valves, see **WIND INSTRUMENTS**.

See A. Carse, *Musical Wind Instruments* (1939). (A. C. B.)

**CORNFLOWER** (*Centaurea cyanus*), a well-known plant of the family Compositae (q.v.), called also bluebottle and bachelor's button. A native of Europe, the national flower of Germany, it

J. HORACE MCFARLAND CO.

CORNFLOWER (CENTAUREA CYANUS)

has become widely naturalized throughout North America. It is a slender, branching annual, from one to two feet high, with narrow, more or less toothed or divided leaves and brilliant, usually blue, flowers, in heads an inch or more across, borne on long leafless stalks. In the United States it is popular for garden planting, being one of the "old-fashioned flowers." In England its cultivation, often from self-sown seed, is so common that breeders have developed many colour varieties notably white, pale blue, pink and deep rose. There are also over

20 related plants in the genus *Centaurea* cultivated in England. See **CENTAUREA**.

(N. Tr.)

**CORNICE**, in architecture, the decorated projection at the top of a wall provided to protect the wall face or to ornament and finish the eaves. The term is used as well for any projecting element which crowns an architectural feature, such as a doorway. A cornice is also specifically the top member of the entablature (q.v.) of a classic order (q.v.); it is in this case divided into three parts, a bed mold, corona and cymatium.

**CORNICHE**, **THE**, the name of a carriage road built by Napoleon I along the Mediterranean slopes of the Maritime Alps between Nice and Genoa. It is famous for its sea and alpine views. The name is applied today to the three roads known respectively as the Grand, the Middle and the Little Corniche (Grande, Moyenne and Petite Corniche), of which the first, ascending directly from Nice, reaches within a few miles a height of more than 1,700 ft., and passing via the Col d'Eze descends via La Turbie to Menton, while the Little Corniche follows the coast route through Beaulieu-sur-Mer, Monte Carlo and Roquebrune.

**CORNING**, a city in Steuben county in southern New York, U.S., is on the Chemung river, 17 mi. N.W. of Elmira. Settlement of the area began in 1789. Named in 1837 for Erastus Corning, an early promoter, the village was incorporated in 1848 and was chartered as a city in 1890. Manufactured products include fibre boxes and pneumatic tools, but the industrial life of Corning, called the "Crystal city," centres about the Corning Glass works. There many forms of artistic and commercial glass are produced, including Steuben glass, flat glass, bulbs, tubing and glass fibres. In 1951, to mark the 100th anniversary of the founding of the works, Corning Glass centre was constructed. Visitors may see the original 200-in., 20-ton, imperfect telescope disk, cast in 1934 for the Palomar observatory in California, where the second casting is now in use; a comprehensive historical collection of glass, dating back more than 3,000 years; and an extensive library dealing with glassmaking. For comparative population figures see table in **NEW YORK: Population**.

(C. C. Ma.)

**CORNISH LANGUAGE:** see **CELTIC LANGUAGES**.

**CORNISH LITERATURE.** The earliest remains in the Old Cornish language are nonliterary: proper names in the Bodmin Gospels and in Domesday Book, 10th-century glosses on Latin texts and a 12th-century vocabulary (British Museum manuscript Cotton Vespasian A XIV) based on Aelfric's Latin-Anglo-Saxon glossary. The forms in the latter, although generally called Old Cornish, correspond to those of Middle Welsh and Middle Breton. The first literary text is a Middle Cornish frag-

BY COURTESY OF KUNSTHISTORISCHES MUSEUM, VIENNA, AUS.

GERMAN KRUMMER ZINK (CURVED CORNETT), WITH ORIGINAL MOUTHPIECE, 16TH CENTURY. IN KUNSTHISTORISCHES MUSEUM, VIENNA, AUS.

ment of 41 lines of a dramatic nature, written about 1400 (British Museum Additional Charter No. 19, folio 491), in which a girl is offered as wife, praised for her virtues and counseled on behaviour fitting to a husband. The long poem *Pascon Agan Arluth* ("The Passion of our Lord," reprinted with Eng. trans., appendix to *Transactions of the Philological Society*, 1860-61) belongs to the 15th century. The matter of its 259 stanzas of eight trochaic heptasyllabic lines with alternate rhymes is based on the Gospels, with additions from the Apocrypha, especially the pseudo-Gospel of Nicodemus, but its literary merit is slight.

The most important Cornish literary remains are a series of long dramatic compositions related to the miracle and morality plays. The earliest and most important is the 15th-century trilogy called the *Ordinalia*. The first part, *Origo Mundi* (2,846 lines) relates the main events of biblical history down to the building of Solomon's temple, where St. Maximilla anachronistically suffers martyrdom. The second, *Passio Domini* (3,242 lines), tells the story of Christ from the temptation to the crucifixion. The third, *Ressurrectio Domini* (2,640 lines), follows on and ends with the resurrection and the ascension. The dialogue is generally dull and there is hardly any dramatic invention except in the scenes of ribaldry. The *Ordinalia* is greater in bulk than all the other remains of Cornish.

Similar in form and technique is a play the unique text of which is in the National Library of Wales (Peniarth ms. no. 105, written in 1504 by "Dominus Hadton")—*Beunans Meriasek* (reprinted with Eng. trans. *Life of Meriasek*, ed. by W. Stokes, 1872), probably composed for performance in Camborne, where Meriasek was the patron saint. Its 4,568 lines show a greater variety of metres and rhyme-schemes than the *Ordinalia*. The material is drawn from Latin and English sources.

The last play, *Gwareans an Bys* ("The Creation of the World," reprinted with Eng. trans., *Transactions of the Philological Society*, no. iv, 1864), 2,548 lines in length, owes much in metre and substance to the first act of the *Origo Mundi*, from which certain passages have been borrowed. The earliest extant ms. of it was written by William Jordan of Helston in 1611, but certain references suggest a pre-Reformation date of composition.

Later minor literary remains—a folktale, a few songs, translations of passages of scripture and several versions of the Apostles' Creed—we owe to antiquaries like William Gwavas, Dr. William Borlase and Edward Lhuyd.

**CORN ISLANDS** (ISLAS DEL MAÍZ). Great and Little Corn Islands are small Caribbean islands in Zelaya department, Nicaragua, between 50 and 59 mi. E.N.E. of Bluefields. Pop. (1959 est.) 1,579. They were leased to the United States by Nicaragua under the Bryan-Chamorro treaty, signed in 1914 and ratified by the U.S. senate in 1916, for use as a naval base to protect the then proposed Nicaraguan interoceanic canal. Except for building a lighthouse on Little Corn Island, the United States has not taken over the land covered by the lease. Principal products of the islands are copra and coconut oil shipped by boat and barge to vegetable oil plants near the north end of Lake Nicaragua. (C. F. J.)

**CORN LAWS.** The term corn laws commonly refers to regulations governing the import and export of grain. In English history it is often applied specifically to the series of laws regulating the grain trade which were repealed, after considerable agitation, in 1846. The term corn, used in this sense, is a generic term for grain.

From the very earliest times, states which had attained to any degree of civilization found it necessary to take measures to ensure a sufficient supply of cereals for the population. In communities which were wholly or mainly agricultural, such measures were only of a temporary nature, resorted to in times of crop

failure or of war. Thus the biblical story of Joseph in Egypt describes steps taken to store grain in years of plenty against the prospect of lean years to come (Gen. xli, 46-57). Similar measures were taken in China at an equally early date. When, however, populations became divided into agricultural and nonagricultural, by the institution of, for example, sacerdotal or military castes, it became necessary to make permanent provision for the feeding of this nonagricultural element. Thus in imperial Rome the tribute payable by conquered races frequently took the form of grain to ensure supplies for Rome itself and for the army. The system of tithes similarly arose from the need for supplying the clergy from the produce of the land cultivated by those to whom they ministered.

In primarily agricultural societies the problem was mainly one of providing for the members of a self-supporting community who were not in a position to produce their own food. With the rise of industrial and commercial classes, the production of the agricultural section was not sufficient to supply the needs of all, at any rate in years when the yield was in any way below normal, and supplies had to be sought elsewhere. From this arose the need for state intervention. It took the form of regulations controlling the domestic marketing of grain to alleviate local shortages and control of the foreign grain trade. Export was prohibited in years of bad harvest or permitted by licence when prices were sufficiently low to indicate sufficiency, if not saturation, in the home market; imports were permitted when high domestic prices gave evidence of a grain scarcity. This arrangement guaranteed a market to the home producer in good seasons but eliminated the risk of famine by allowing imports in times of dearth.

Before the emergence of nation-states in Europe, principalities and city-states had their own corn laws, based on the same principles of safeguarding domestic supplies and allowing exports only when there was a surplus. In modern times, instead of actual prohibition of import or export, it became the practice to impose duties so high as to be prohibitive, sometimes in conjunction with specified price limits or with a sliding scale dependent on prices in the home market. With the rise of intensive cereal culture in the United States, Canada, Rumania and elsewhere, protective import duties were levied in certain countries to prevent the flooding of the home market with cheap grain to the detriment of the domestic producer.

**English Corn Laws Before 1500.**—The earliest evidence of regulations governing the export and import of grain is of penalties imposed in 1177, 1178, 1180 and 1183 on persons exporting grain without licence. This prohibition on export, which was reaffirmed in the Great Winchester Assize of Customs in 1204, remained in force until 1394, although licences to export were granted to individuals and suspended in times of war or harvest failure. Imports of grain were permitted throughout the period, although the customs accounts suggest that the amount involved was negligible in all but scarce years. In 1394 the grain policy of the realm was reversed and exports were permitted freely so long as the customs and subsidies were paid. The king's council retained the right to prohibit export in times of emergency. The act became inoperative before 1426, but was reaffirmed in that year. In 1437 a new statute was passed permitting export on three conditions: grain was not to be exported to enemy countries; customs were to be paid; and the price at the port of shipment was not to exceed specified amounts, for instance, 6s. 8d. a quarter for wheat. The act lapsed in 1439, was renewed in 1442 and made permanent in 1445, although from time to time thereafter it was suspended by royal proclamation, usually in the interests of London's food supply. A complementary import policy was put into operation in 1463 when imports of grain from abroad were prohibited except when the home price exceeded 6s. 8d. a quarter.

Some historians have held the view that the corn laws for the period before 1500 lacked any consistent purpose. Others have offered explanations set within the framework of constitutional and economic development, though these, for want of sufficient evidence, cannot be finally proved. The changes of policy have been described as a political struggle between the crown and parliament, in which the crown favoured the system of special licences

for its own financial advantage while the commons opposed them on the grounds that they resulted in dearth. They have been explained in terms of a struggle between consumers and producers, the consumers demanding a regular supply of grain at low prices and therefore favouring free imports and a prohibition on exports, the producers anxious to ensure a market and a fair price in good as well as bad years by securing restrictions on imports and freedom of export. The heightening of the conflict between consumers and producers has been attributed to marketing developments in the 12th and 13th centuries. Hitherto, the bulk of the traffic in grain had been confined to groups of manors managed as one organization under a common lord. With the growth of centres of consumption in the towns a local marketing system took shape, serving urban communities with the food surpluses from surrounding districts. Against this background of marketing history, the policy of the 14th and 15th centuries can be understood as an attempt by parliament to reconcile the opposing claims of manorial producers, the crown and the newly risen and influential class of town consumers.

How far the policy was adjusted to the total grain yield of the kingdom or to population needs is a question not adequately answered. The freer policy of the 15th century prevailed at a time of agricultural stagnation, not of rapid advance. It did not effect an increase in the volume of exported grain. Yet the continuance of the policy throughout the 15th century suggests that it was rooted in economic realities. It presupposed the ability of home producers to feed the population and leave a surplus of grain for export in all but scarce years. Such an assumption did not necessarily follow from any spectacular increase in yield. Yields per acre seem to have altered little in the 14th and 15th centuries, while the cultivated area as a whole diminished. But in view of the decline of population between about 1320 and 1470, a policy that presupposed a new relation between the needs of the population and the yield of the harvest may not have corresponded ill with the facts.

**Tudor and Early Stuart Policy.**—A rise in prices at the beginning of the 16th century, though modest compared with that which followed in the 1540s, was accompanied by the rapid advance of enclosure in the midlands and a consequent increase of pasture in these counties at the expense of tillage. Fears were aroused concerning the adequacy of the domestic grain supply. Following several royal proclamations in which the 1445 act had been temporarily suspended, parliament decided in 1534 to prohibit entirely the export of grain in the hope of keeping food prices down. Other measures were taken to restore the arable area by prohibiting enclosure and the conversion of tillage to pasture. Modern historians differ on whether the aggregate yield of the kingdom was reduced by the spread of pasture farming in the midlands or whether the shortages were principally the result of the disorganization of the internal marketing system. The growth of London and other industrial centres imposed a strain on local supplies, which were further taxed by occasional bulk purchases of food by the government for the armed forces.

To contemporaries, however, it was enclosure and the conversion of arable land to pasture which threatened the food supply and bred the twin evils of unemployment and social unrest. The solution put forward by John Hales, one of the economic reformers of Edward VI's reign, was to permit the export of grain and prohibit that of wool, in order "to make the profit of the plough to be as good, rate for rate, as the profit of the graziers and sheepmasters." When the immediate crisis had passed, the export ban was gradually lifted. In 1555 export was permitted under licence, or without licence when prices did not exceed 6s. 8d. a quarter for wheat, 4s. for rye and 3s. for barley. That the original intention of the act was to tighten the regulations against export was evident in the preamble containing complaints against merchants who in spite of the 1534 act had exported grain and had thereby caused dearth and high prices. Severe penalties were laid down for the future. The clause allowing exports at certain price levels was appended later as a result of protests from the East Anglian grain-growing districts. In 1563 an act, based on mercantile principles (*see* MERCANTILE SYSTEM), authorized the export of grain

so long as it was carried in ships belonging to English-born subjects and so long as prices did not exceed 10s. per quarter for wheat, 8s. for rye, peas and beans and 6s. 8d. for malt and barley. It was designed not only to promote the grain trade but to foster the development of the navy, the shipping industry and the fish trade.

It was superseded in 1571 by an act expressly in the interests of tillage, in which the grain supply was viewed realistically as a series of regional problems rather than a national one. Export was allowed at the discretion of the local justices of the peace according to the current price of grain in the district. Two further clauses provided that grain must be exported to friendly nations and that it must be carried in ships belonging to Englishmen. The policy of local regulation led to the abuses of price manipulation and was abandoned in 1593 in favour of central control and one price standard for the whole kingdom. Export was allowed when prices were not more than 20s. a quarter for wheat and for other grains correspondingly. In later acts the customs rates and price limits were revised to take account of the general price rise, but the principles of the policy remained unaltered until the Restoration. In 1604 the price limit for wheat was fixed at 26s. 8d., in 1624 at 32s., in 1656 at 40s., in 1660 at 40s. and in 1663 at 48s.

Although the grain export laws after the middle of the 16th century were couched in terms encouraging to the producer, their practical consequences were otherwise, since the price did not often fall below the statutory limit. Between 1554 and 1563, and again between 1593 and 1600, grain was never cheap enough to be exported, while in 1563–71 and 1600–60 low prices prevailed in only seven years. Moreover, the crown continued to exercise the right to suspend and override the laws whenever it deemed it desirable in the interests of the consumer. Nevertheless, the producer was not entirely frustrated by the statutes, since a certain amount of grain was sent abroad whatever the laws in operation. The contemporary historian William Camden held the view that the laws permitting export greatly accelerated agricultural development, while the customs accounts show a doubling of exports in the years 1500–34 and another period of rapid increase from about 1563 until the end of the century. The decline in exports in the early 17th century can be accounted for by the steady increase in the supply to London. The port of King's Lynn, for example, which sent only 6% of its coastwise shipments to London in the mid-16th century, sent nearly 40% by 1600 and about 50% in the second half of the 17th century.

Import regulations between 1500 and 1660 were neglected. The 1463 act prohibiting imports except when grain prices were high had lost all meaning by the mid-16th century because of inflation. In any case, imports had come to play a vital role in supplying London in years of scarcity. Any attempt to enforce the ban on imports would have injured that section of the community which virtually controlled the grain policy of the kingdom. The 1463 act was formally repealed in 1624, but nothing took its place until 1663.

**Corn Laws, 1660–1791.**—In satisfying the demand for corn in London, the grain trade of the kingdom came to be focused increasingly on the capital. At the Restoration, when the export surplus assumed substantial proportions, London kept its place as the principal clearinghouse for the foreign grain trade.

A new policy of plenty was initiated in 1663 by an act imposing a duty of 5s. 4d. a quarter on wheat imported from abroad when the home price did not exceed 48s. Correspondingly heavy rates were laid down to control the import of other kinds of grain. The duty was arranged on a sliding scale in 1670, making it prohibitive in all but scarce years. The home farmer thus enjoyed a virtual monopoly of the domestic market, except when famine threatened. By the same act he was allowed to export grain whenever wheat prices did not exceed 48s. a quarter. The express purpose of the policy was to encourage tillage as a means of promoting trade and bringing waste lands into cultivation. In 1670 it was carried a stage further by allowing the export of grain regardless of price, provided that the customs rates laid down in 1660 were paid. There followed in 1673 the grant of a bounty of

5s. a quarter on wheat exported when the home price did not exceed 40s., of 3s. 6d. on rye when it did not exceed 32s. a quarter and of 2s. 6d. on malt and barley when they did not exceed 24s. a quarter. Because of a bad season the act did not come into effect for a year or more, but there is evidence that it was in force from Michaelmas 1674 to 1675 and again between 1680 and 1681. About £150,000 was paid out in bounties during the period.

The Bounty act of 1673 has been interpreted as a political triumph for the gentry over the policy of paternalism to which the early Stuart governments adhered. It was also a sound economic measure adapted to a greatly improved level of agricultural production. Whereas in the 16th century England had been obliged to import considerable quantities of grain in scarce years, a century later it had plenty and to spare. Such a transformation can only be explained as a consequence of technical improvements in farming, of land reclamation and of increasing specialization in land use. The commons, which in 1621 argued that grain imports should be prohibited because England could now feed itself, argued prematurely, but their opinion was more than substantiated a century later when Daniel Defoe described England as the supplier of Europe. By that time the value of grain dispatched abroad from London had risen from £4,315 in 1663 to an average of £274,141 per annum between 1699 and 1710. It rose to £835,394 between 1746 and 1765.

A second Corn Bounty act was passed in 1689, allowing 5s. on every quarter of wheat exported when the home price did not exceed 48s. Beyond a statement in the preamble of the act that experience had justified the bounty when prices were low, the reason behind it was not made clear. Arthur Young deemed it a reward to the landed classes for their part in establishing William III on the throne. Sir John Dalrymple regarded it as a gift to the Tories for accepting the land tax. Price tables suggest that the preamble of the act should be taken at its face value, that the bounty was due to the low prices then prevailing. Seeking a remedy for the depression, parliament understandably reverted to the precedent of 1673. The effect of the bounty was not immediately reflected in increasing exports, for poor harvests kept prices high between 1689 and 1714, while in 1698 and 1709 exports were prohibited entirely. However, they expanded rapidly between 1715 and 1750 except for three years between 1727 and 1729, and 1739 and 1740, when home crops were poor. After 1750 successive years of bad harvests brought scarcity and high prices in their wake. This aggravated a problem which was already present in the growth of population and the development of industry. A ban on exports operated between 1757 and 1759 and almost continuously after 1765. Finally, in 1773 the government passed an act forbidding exports except when wheat prices fell below 44s. a quarter. It continued in force until 1791. The fact that English farmers were no longer able to meet the home demand was reflected also in increasing imports from abroad from 1773 onward.

Although the bounty system was an innovation in 1673, it was not until after 1750 that public interest was aroused by the growing cost of bounties to the taxpayer. Economic arguments against the preferential treatment of farmers were coupled with allegations of fraudulent practices in the distribution of payment. The bounties were attacked by Adam Smith on the grounds that they interfered with the natural course of trade and led to high prices at home. They were defended by Arthur Young because they had eliminated sudden price fluctuations and, by encouraging farmers to expand production, had brought about a steady fall in prices. It is nowadays generally agreed that prices were stabilized by the bounties, that farmers enjoyed a security unknown before and that the export trade grew in consequence. The opposition developed out of a changed situation, when industry began to challenge the primacy of agriculture in the national economy.

(I. J. T.)

**The 1791 Act and the French Wars.**—There were weaknesses in the machinery for administering the 1773 act, but it was not until 1790 that efforts were made to secure new legislation. The landed interest feared substantial imports and agitated for additional protection, but counterpetitions were sent from the manufacturing and commercial centres attacking export bounties and

demanding cheap food. This clash between different interests dominated much of the politics of the subsequent 60 years. In parliament there was a majority of landlords and effective political power was used to support what came to be a clearly sectional interest.

Despite urban complaints the 1791 act introduced changes which favoured agriculture. The price at which imports were allowed at a nominal figure of 6d. was raised to 54s.; a duty of 2s. 6d. was levied from 54s. to 50s., while at 50s. and under a prohibitory duty of 24s. 3d. was imposed. Colonial preference was introduced for Ireland and North America, a feature which was maintained in every subsequent corn law until 1846. Wheat exports were permitted when the price was less than 46s. and a bounty of 5s. was paid when the price was less than 44s. A warehouse duty of 2s. 6d. was imposed on foreign wheat imported for re-export.

The 1791 act was followed two years later by a long period of war. Customary commercial relations were violently disturbed and freight, insurance and other charges on imports and exports were multiplied fivefold. War conditions as much as corn laws gave a "natural protection" to English farmers and landlords; at the same time population growth increased the seriousness of the food problem. Bad harvests produced political discontent as well as hunger and the government had to resort to special measures in crisis years. After the bad harvest of 1795 the price of wheat rose to above 100s., the highest since the late 16th century. Food riots forced the government to pass scarcity laws and to pay bounties on imported grain, including rye. In the towns there was popular outcry against forestallers, engrossers and regraters, while in many parts of the countryside local magistrates copied the Speenhamland example and fixed poor relief in terms of bread prices. The crisis of 1799–1801 was even more severe: there were demands for peace, the extension of government controls and an increase in enclosure, as well as rioting against grain dealers. Prices continued high until 1801, when in March the average was 154s. 2d. Relief came not from government policy but from the moderately abundant harvests of 1801, 1802 and 1803. As grain prices fell there were cries, this time, of agricultural distress and an 1804 act actually increased the protection granted in 1791.

The provisions of the act were inoperative, however, for between 1805 and 1813 there was a sequence of bad harvests and high prices. There was little outcry against the corn laws until 1811, for it was recognized that Napoleon's blockade and not parliament was preventing the import of foreign grain. In the meantime landlords and farmers prospered. Rents and profits rose and there was a great increase in the extent of arable cultivation and an improvement in agricultural methods.

**Protection in the 19th Century.**—After the enormous harvest in 1813 there was a rapid fall in wheat prices (June 1813, 117s. 10d.; May 1814, 69s. 7d.) and farmers and landlords realized that the golden age could not last indefinitely. Even before the bad harvests a select committee, appointed in March 1813, had demanded additional protection. After the price fall there was a crop of protective resolutions. The first idea broached in parliament was an increase in the duty on foreign imports along with the prices at which it was levied, and freedom of export, without bounty, whatever the home price might be. The latter suggestion was passed into law in June 1814, but there was great popular clamour in the cities and manufacturing districts against substantial duties on imports. Although the outcry persisted, in 1815 the government carried its important new corn law, fixing 80s. (14s. more than during the wars) as the price at which imports of wheat were allowed duty free. Manchester was as ineffective against the landed interest represented at Westminster as was the London mob, which rioted near the house of commons. In 1815, however, the manufacturers themselves were for the most part unwilling to give up protection on manufactured goods and were consequently compelled to talk in crude terms about comparative costs of production.

The 1815 act was designed to maintain the price of wheat in peacetime at 80s., but, as William Cobbett correctly predicted, far from producing the expected result it merely provoked a sense of injustice. Between 1815 and 1822 grain prices fluctuated vio-

lently. Changes in currency legislation were often blamed for the difficulties. During the wars suspension of cash payments (from 1797) and liberal use of paper money in loans and discounts maintained high prices. In 1819 it was decided to resume cash payments. The general price level had already begun to fall when payments were resumed in 1821 and the nation was beginning to feel the naked weight of war debt. Some spokesmen of the agricultural interest claimed that 1819 canceled out the benefits of 1815. Others blamed high taxation for their distress and pressed for the setting up of select committees in 1821 and 1822. Although the prime minister, Lord Liverpool, pointed out that it was beyond the scope of parliament to legislate a market for agricultural produce, a modification of the 1815 act was eventually made in 1822. Foreign wheat was to be excluded completely until the price reached 70s.: above that figure it was to be admitted only after duty had been paid according to a scale.

The act of 1822 never operated, except occasionally in the case of barley, for wheat prices never reached 80s. The agricultural interest, in short, was unable by legislation to counterbalance economic tendencies leading to a fall in prices and rents. By the time it realized that the tendencies could not be checked, manufacturers and town labourers had already begun a drive to reduce protection still further and even to abolish it altogether. Agitation against the corn laws increased particularly after 1825 when William Huskisson substantially reduced duties on manufactured articles and raw materials. Violent attacks were made on the landlords as a social class in widely read pamphlets, such as Thompson's *Catechism on the Corn Laws*.

Two new government measures in 1827 and 1828 did little to satisfy the most determined advocates of either side. In 1827 George Canning introduced a new system of duties, abandoning the principle of protection by absolute exclusion of wheat up to a certain price and employing a sliding scale of duties. His death and the consequent change of ministers involved the failure of his project, but in 1828 Charles Grant introduced a new sliding scale with more abrupt leaps in the amount of duties levied at particular price points. A duty of 34s. 8d., for instance, was levied when the price of wheat was 52s., but fell to 1s. when the price was 73s. Similar scales were applied to other kinds of grain and colonial preference was increased. The 1828 act assisted the speculator as much as the farmer and it did little to improve the prospects of English agriculture.

**Repeal of the Corn Laws.**—Because of preoccupation with parliamentary reform there was little direct pressure for a smaller fixed duty on grain or total repeal of the corn laws until the issue was raised again in 1838. A powerful new organization, the Anti-Corn Law league, operating from Manchester, mobilized the new wealth of industrial Britain. Its leader, Richard Cobden, was successful not only in stirring opinion in the country but also in influencing the Conservative prime minister, Sir Robert Peel. On his own initiative Peel introduced and carried in 1842 a new sliding scale of duties, better adjusted to current values, and inaugurated a program of fiscal reform and freer trade. The league claimed that only total repeal would settle at the same time the grievances of the manufacturers, hard hit by industrial depression, and the poor, burdened with the high cost of living. Although it was a self-proclaimed middle-class organization, it adjusted its economic arguments to suit its audiences and carried its campaign to tenant farmers in the countryside, attempting to differentiate their interests from those of the landlords. The landlord was depicted as the villain of society; he took the place of Adam Smith's middleman as the target of social criticism.

The propaganda of the league was so successful that Peel himself, although not a doctrinaire free trader, began to waver. He was always open to argument and by 1844 he found the main argument of the league incontrovertible. Finally, influenced by the failure of the potato crop in Ireland, he put an effectual end to the history of the corn laws by his famous act of 1846. The maximum duty on foreign wheat, when the price was under 48s., was immediately reduced to 10s., with lower duties as prices rose

above the scale. From Feb. 1849 all duties on grain were to cease, except for a nominal impost of 1s. In 1869 even this nominal duty was abolished by Robert Lowe.

Repeal in 1846 split Peel's Conservative party, but it did not spell the ruin of British agriculture. The middle years of the 19th century were the golden age of English farming, and it was the improvement in international transport and the sharp increase in the imports of American wheat in the 1870s which effectively challenged Britain's cereal farming and destroyed the natural protection afforded not by legislation but by geography.

**20th-Century Policies.**—There was a late-century revival of protectionism. In 1902, for revenue-raising purposes, a registration duty of 3d. per hundredweight was imposed on imported grain and 5d. per hundredweight on imported flour, and although these duties were repealed a year later, Joseph Chamberlain, who became the leader of a tariff reform movement in 1903, considered them a desirable basis for increased protection of home-grown grain and preference for grain grown in the empire. He hoped, as did the prime minister of Canada, largest grain-growing country in the empire, that new corn laws would lead to increased reciprocal preferential trade between empire countries. "Free trade within the empire" was the new objective.

A closer union of the empire depended upon a fiscal revolution at home. The revolution was not forthcoming before 1914. Although the Unionist party split as Peel's party had split in 1846, loyalty to free trade principles proved strong. Measures of protection were given a greater stimulus by exigencies of 20th-century war and depression than by efforts of politicians.

Between 1914 and 1918 imports and exports were under strict government control and farmers' prices were guaranteed. This policy ended in 1920, for despite agricultural pressure politicians were still afraid to violate free-trade traditions and to tax foodstuffs. It was not until after the slump in wheat prices and world economic collapse that the National government, unwilling to give direct protection to wheat farmers, passed the Wheat act of 1932. By this time home wheat production represented only a small part of the total British demand and combination of producers could never have been effective in influencing the level of home prices. The Wheat act stabilized sharply fluctuating prices by imposing a virtual tax upon the consumer. All wheat growers had to inform the wheat commissioner of their sales and prices. If at the end of the year the average sales price on all transactions was less than a standard price of 10s. per hundredweight, each grower received the difference between his average and 10s., multiplied by the quantity of his sales. The sums thus distributed were derived from a processing tax on all flour delivered for consumption in the United Kingdom. In consequence bread prices rose by as much as  $\frac{1}{4}$ d. on the 2d. loaf. A great expansion in wheat acreage was achieved only at the expense of dearer bread. In 1937 the principle of price guarantee was extended on slightly different lines to oats and barley growers, the subsidies being paid not directly by the consumer but by exchequer grants.

The return to producers' protection in 1932 was not reversed. After 1939, in war conditions, tight import restrictions were imposed, farmers' guarantees were given and strenuous efforts were made to increase the acreage of cereal production. Balance of payments difficulties after 1945 made the continuation of war policy imperative, and the Agriculture act of 1947 emphasized the need for developing "a stable and efficient agricultural industry capable of producing such part of the nation's food as in the national interest it is desirable to produce."

The phrase "national interest," which would have left Cobden and John Bright unmoved, recalled mercantilist arguments about the corn laws, but policy after 1945 was different both from that of the 18th century and from that of 1932 and 1937. Dependence upon foreign imports had to be acknowledged, though the imports were restricted and directed by long-term bulk-buying contracts. The price-insurance schemes themselves were designed not so much to save the farmer from keeping pace with the steady growth of technical progress overseas as finally to exorcise his fear of being squeezed by a slump in world prices. Protection was related to

national planning rather than to the interest pressure of a particular group of producers.

**CORN PICKER:** see HARVESTING MACHINERY.

**CORN PLANTER:** see PLANTING MACHINERY.

**CORN SALAD** (LAMB'S LETTUCE), *Valerianella olitoria* (family Valerianaceae), a weedy annual, native of southern Europe but naturalized in cornfields in central Europe and in various parts of the United States and Canada, and not uncommon in Britain. In France it is used in salads during winter and spring as a substitute for lettuce, but it is less esteemed in England. Principally grown are a round-leaved variety of *V. olitoria* and Italian corn salad, a distinct species, *V. eriocarpa*.

**CORNUS** is the genus name of about 45 species of shrubs and small trees of the family Cornaceae (*q.v.*) to which the name dogwood is applied. See Dogwood.

**CORNUTUS, LUCIUS ANNAEUS**, Stoic philosopher, flourished in the reign of Nero. He was a native of Leptis in Libya, but resided for the most part in Rome. He is best known as the teacher and friend of Persius, whose satires he revised for publication after the poet's death, but handed them over to Caesius Bassus to edit, at the special request of the latter. He was banished by Nero (in 66 or 68) for having indirectly disparaged the emperor's projected history of the Romans in heroic verse (Dio Cassius, lxxii, 29), and disappears from history. He was the author of various rhetorical works in both Greek and Latin (*Rhetorikāi technai, De figuris sententiarum*). His philosophical treatise, *Theologiae Graecae compendium*, is still extant; it is a manual of Stoic etymological interpretation of popular mythology (ed. by C. Lang, 1881). Simplicius and Porphyry refer to his commentary on the *Categories* of Aristotle, whose philosophy he is said to have defended against an opponent Athenodorus in a treatise *Antigraphe pros Athenodoron*. Excerpts from his treatise *De enuntiatione vel orthographia* are preserved in Cassiodorus.

In the middle ages several critical works were falsely attributed to him; e.g., the so-called *Disticha Cornuti* (ed. by Hans Liebl, Straubing, 1888).

**CORNWALL**, the southwesternmost county of England, is bounded on the northwest and west by the Atlantic ocean, on the south by the English channel and on the east by Devon. The area is 1,357 sq.mi., including the Scilly Isles (*q.v.*), which are administered separately.

**Physical Features.**—The form of Cornwall is that of a peninsula, 75 mi. long and 45 mi. broad across the base, Lizard point being the most southerly extension and Land's End (*q.v.*) the most westerly point of the mainland. It owes its main features to the folding movement of the Armorican system complicated by a series of granite intrusions. The latter form moorland bosses (small batholiths) decreasing in height from east to west. Dartmoor (*q.v.*) in Devon is the largest and highest; Bodmin moor reaches 1,395 ft. in Brown Willy; Hensbarrow Beacon is 1,026 ft.; Carnmenellis and the St. Just boss are lower; a further granite mass, now largely submerged, forms the Scilly Isles. The lower-lying regions are mainly of folded slaty rock of Devonian age, striking largely east to west, with some limestone; in the extreme northeast there are Carboniferous grits and shales. From

REN DARBY

LAND'S END, CORNWALL, SHOWING UNUSUAL CLIFF FORMATIONS

Tintagel head northward to Hartland point in Devon the distorted strata form steep cliffs because of the rapid maritime erosion that goes on. The veins of ore are chiefly in the slaty rock near the granite masses which themselves give kaolin by decomposition of feldspar. A Tertiary, supposedly Pliocene, uplift and tilt apparently gave especially the south-flowing streams an additional impetus and led to the cutting of deep valleys in what the uplift had converted from a peneplain into a plateau or a succession of plateaus. Post-Pleistocene sinking gave rise to the sunken estuaries of south Cornwall, and the drainage lines are chiefly those between the granite bosses. The Tamar (*q.v.*), which forms most of the boundary between Devon and Cornwall, drains between Dartmoor and Bodmin moor into its great southern estuary; between Bodmin moor and Hensbarrow Beacon the Camel drains northward to Padstow bay, and the Fowey southward into a long estuary; the Fal estuary is placed between the Hensbarrow and the Carnmenellis bosses; and there is a low line across from Mount's bay to St. Ives bay between Carnmenellis and the St. Just boss. In Mount's bay is St. Michael's Mount (*q.v.*), a precipitous granite island joined to the mainland at low tide by a causeway, the slaty rocks (called killas) having been washed away on all sides but the north.

The climate is mild and moderately sunny. High winds are common in autumn and winter and sea mists in spring and autumn. The average temperature for January is 43.4° F. at Bude and 44.5° at Falmouth. Rainfall is heavy and, though only 33.4 in. per annum at Bude, it reaches 43.6 in. at Falmouth and 49.4 in. at Bodmin. The vegetation in shelter is luxuriant and southern in type, and in some places along the southern coast, known as the Cornish Riviera, subtropical plants are grown. About 360 sq.mi. of the county have been designated as Areas of Outstanding Natural Beauty; with the exception of Bodmin moor, these areas are located along the coast. The beauty of the coast line, especially Land's End and the Lizard, and the little fishing towns such as St. Ives, Looe, Fowey, Polperro, Newlyn and Mousehole, attract many artists. The National trust owns 9,395 ac., with 1,742 ac. under restrictive covenant.

**History.**—The wind-swept moorlands and cliffs gave opportunities for early settlement, and when the use of metal was beginning to spread, or just prior to this, western Cornwall became important, as its wealth of megalithic monuments shows. They include dolmens such as those of Lanyon, Mulfra, Chun and Zennor. Monoliths have a wider distribution, those in the parish of St. Buryan being well known. The principal circles are the Hurlers, near Liskeard, the Boskednan, Boscawen-un and Tregeseal circles, and the Merry Maidens near Lamorna. All these, except the Hurlers, are in the Land's End district. There are also alignments on the moors near Rough Tor and Brown Willy. This culture formed part of a movement from the Mediterranean which brought Cornwall and the southwest into touch with Brittany. A few Early Bronze implements have been found. The coastal

promontories and river estuaries are protected by clusters of earthworks of presumed Iron Age date, but mining operations have destroyed so many that it is impossible to argue from their type and distribution. Roman occupation and Saxon colonization of the lands farther east caused westward pressure, and it is to these influences that must be assigned the emigration of Brythonic-speaking people into southwest England and from there to Brittany. Remains of Celtic Christianity in Cornwall include crosses dating from the 6th century onward, inscribed sepulchral stones, generally of the 7th and 8th centuries, and oratories. These have their parallels in Ireland, as the prehistoric contacts with Ireland and Wales and Brittany were maintained in early Christian times. In all these regions dedications to local saints are a feature. The oratory buildings are very small and rude, always placed near a spring. The best example is St. Piran's near Perranzabuloe, which lay buried in sand dunes until 1835. St. Piran, a missionary sent by St. Patrick in the 5th or 6th century, became the patron saint of the tin miners. Cornwall has many associations with the Arthurian legend.

Cornwall was the last portion of British territory in the south to submit to the Saxon invader. In 815 Ecgbert directed his efforts toward the subjugation of the West Welsh of Cornwall, and after eight years' fighting compelled the whole of Dyvnaint (west Wales, Cornwall) to acknowledge his supremacy. Assisted by the Danes, the Cornish revolted, but were again defeated in 838 at the battle of Hengestesdun (Hingston Down in Stoke Climsland). Ninety years later Aethelstan banished the West Welsh from Exeter and made the Tamar the boundary of their territory. By the time of Edward the Confessor nearly all the land in Cornwall was held by men bearing English names. As the result of the Norman Conquest less than one-twelfth of the land (exclusive of that held by the church) remained in English hands. Most (248) of the manors were assigned to Robert of Mortain and became the foundation of the earldom. Since a charter of 1337 the eldest son of the sovereign has been duke of Cornwall, this being the oldest dukedom in the kingdom. In the 15th century Cornwall strongly supported the Lancastrian cause, and its remoteness from the capital made it a potential field for revolt. This is seen in the support given to the Thomas Flamock (or Flamank) rebellion in 1497, to Perkin Warbeck in the same year and to the Humphry Arundell rebellion over the religious question in 1549. The king's Cornish troops led by Sir Bevil Grenville defeated Col. Ruthin on Bradock down, while Sir Ralph Hopton (q.v., later Baron) triumphed over the parliamentarians at Stratton. The whole county was thereby secured to the king, but dissensions hastened the overthrow of the royalists. The 18th century was remarkable for the fervour shown by Cornishmen in the Methodist movement.

The old Cornish language survives in a few words still in use in fishing and mining communities, as well as in names of persons and places (e.g., names with the prefixes Tre, Pol, Pen meaning "dwelling," "pool," and "summit or headland" respectively), but the last persons who spoke it died toward the end of the 18th century. The language belonged to the Cymric or Brythonic division of Celtic, in which Welsh and Breton are also included. Three miracle plays in Cornish are important relics of the language. (See CELTIC LANGUAGES; CORNISH LITERATURE.)

Cornish wrestling is confined to Cornwall and Brittany, where it was introduced from Cornwall in the 5th and 6th centuries A.D. It has been played in Cornwall since remote times, and there is a legendary account of a contest between a Cornish giant, Goemor, and a Trojan warrior, Corineus, said to have taken place about 1000 B.C. Cornish wrestlers fought at Agincourt under a banner that is still the symbol of the Cornish Wrestling association. The wrestlers wear special canvas jackets, fastened in front by cords, and no shoes. (See WRESTLING.) A full description of the sport is given in Richard Carew's *The Survey of Cornwall* (1602) and details of its history in the *Journal of the Royal Institution of Cornwall*, new series, vol. ii, part 2 (1864- ).

**Population and Administration.**—The population at the 1961 census (including the Scilly Isles) was 342,301. In 1861 the population was 369,390 and had shown an increase up to that

date. There are 12 municipal boroughs: Penzance (19,281), Falmouth (17,621), Truro (13,336), St. Ives (9,346), Saltash (7,425), Bodmin (6,214), Helston (7,086), Launceston (4,524), Liskeard (4,492), Penryn (4,451), Fowey (2,263) and Lostwithiel (1,955). Bodmin is the county town and the assizes and quarter sessions are held there, but the county offices are in the cathedral city of Truro. There are eight urban districts of which the largest are Camborne-Redruth (36,110), St. Austell (25,074) and Newquay (11,881), and ten rural districts, excluding the Scilly Isles which are under a separate council. The islands form one of the 22 petty sessional divisions. In addition, Penzance has a separate commission of the peace and court of quarter sessions.

The county court was held at Lostwithiel and the assizes at Launceston in the 13th and 14th centuries. In 1716 the summer assize was transferred to Bodmin and after 1836 both assizes were held there. Cornwall had its own bishop from the 7th century until 1018. In 1049 the see of the united dioceses of Devon and Cornwall was fixed at Exeter. Cornwall became an archdeaconry soon after and was reconstituted a diocese with its see at Truro in 1877.

Two members for the county were summoned by Edward I to the parliament of 1295, and two continued to be the number of county members until 1832. Six boroughs were granted the like privilege by the same sovereign. Between 1547 and 1584, 15 additional towns and villages received the franchise, with the result that, between the latter date and 1821, Cornwall sent no fewer than 44 members to parliament and became notorious for the number of its rotten boroughs (see BOROUGH). The allocation of members proportionately to the population continued irregular until 1885. There are now five parliamentary divisions, Bodmin, Falmouth and Camborne, St. Ives, North Cornwall and Truro, each returning one member.

**Industries and Communications.**—The main sources of income in Cornwall are agriculture, the tourist trade, quarrying, engineering, ship repairing, mining and fishing.

There are pasture and arable farms, and in the valleys the soil is frequently rich and deep. Oats and mixed grain form the main cereal crops; green fodder crops, turnips and swedes, potatoes and mangolds make up the bulk of the root crops. Cattle, chiefly of the Devon breed, sheep, pigs and poultry are reared. Excluding rough grazings, about three-quarters of the total area of the county is under crops and grass. Because of the favourable climate, fruit, flowers and vegetables are cultivated in the vicinity of Mount's bay (flowers, broccoli, early potatoes), the Fal valley (flowers, broccoli, early potatoes, vegetables) and the Tamar valley (top and soft fruit, flowers, vegetables). The Scilly Isles also share in the market gardening industry, notably for flowers. The care of woodlands and the planting of new areas are largely undertaken by the Forestry commission.

The fisheries of Cornwall and Devon are the most important on the southwestern coasts. The pilchard is in great measure confined to Cornwall and the neighbourhood of the Scilly Isles. Apart from a short interval in the spring, pilchards are caught all the year round by drift nets off the southern coast. They are mainly disposed of by canning, and surplus catches are cured and packed locally for export to Italy. Ray, skate, turbot, cod, conger and dogfish are caught by long lines, and sole, plaice, skate and whiting by trawls. The principal fishing stations are Newlyn, Mevagissey and Looe, but boats are employed all along the coast.

An important source of income, comparable with agriculture, is the tourist trade. Many of the small seaside towns, such as Bude, Stratton, Newquay, St. Ives, Falmouth and Looe, have become holiday resorts. Falmouth is the yachting centre, but Fowey and Penzance are among the many safe harbours. The principal ports are Hayle, Penzance, Truro and Penryn. Falmouth is a ship-repairing centre. A main railway line passes through the county to terminate at Penzance and there are 150 mi. of trunk roads in Cornwall. There is a civil airport at St. Just and another on St. Mary's, Scilly Isles.

**Mining.**—The tin of Cornwall has been known and worked from the Bronze Age. By ancient charters the tanners were exempt

from all jurisdiction (save in cases affecting land, life and limb) other than that of the stannary (tin mine) courts. A tax on the tin, after smelting, was paid to the earls and dukes of Cornwall. The smelted blocks had to be coined—that is, stamped with the duchy mark—before they could be sold. In 1838 the dues on coinage were abolished and a compensation awarded to the duchy instead. Cornish miners directed successful developments of mining in many parts of the world, and much emigration took place in the middle of the 19th century. The industry suffered from periods of depression (for example, before the accession of Elizabeth I, who introduced miners from Germany to resuscitate it), and in modern times the shallow workings, from which tin could be easily "streamed," became practically exhausted. The deeper workings are more costly and foreign competition is greater. There was a slight revival during World War I, but later mining greatly diminished. A rise in the price of tin during 1926–28 caused renewed activity especially in the Camborne-Redruth district, but production of tin ore has continued to decline, the surviving mines of importance being at Pool (Camborne) and Pendeen (St. Just), producing tin and arsenic. There was also a small wolfram mine at Castle-an-Dinas, near St. Columb. No mine seems to have been worked exclusively for copper before 1770. In 1718 John Coster drained the deeper mines and introduced an improved method of dressing ore. In 1851 the mines of Devon and Cornwall were estimated to furnish one-third of the copper raised in Europe. Iron (brown hematite) has been worked near Lostwithiel and elsewhere. The St. Austell district produces china clay (kaolin), and after its extended use for paper filling and the textile trade it became an important commodity. China stone is also quarried near St. Austell. Production after World War II exceeded 60,000 tons a year.

Igneous and metamorphic rocks are quarried mainly for road stone. The largest groups of quarries are Penlee (Penzance), St. Keverne (Lizard), Clicker Tor and Hingston Down (southeastern Cornwall). Production of granite for monumental and constructional work accounts for less than 1% of total igneous rock production. Fine slate is quarried and largely exported, as from the Delabole quarries near Tintagel (worked since Tudor times), and serpentine is quarried in the Lizard district.

Camborne-Redruth, formerly the principal mining area, manufactures mining equipment and has a civil engineering plant. After World War II it attracted a greater variety of industries, including several textile firms.

**CORNWALL**, a city of Ontario, Can., seat of the united counties of Stormont, Dundas and Glengarry, on the left (north) bank of the St. Lawrence river, about 70 mi. S.W. of Montreal, is a port of entry from the United States via the Roosevelt bridge and headquarters of the Canadian St. Lawrence Seaway authority. Founded as New Johnstown by United Empire Loyalists in 1784, opposite the Indian village of St. Régis, in 1797 it was renamed in honour of the duke of Cornwall, who became George IV. It was incorporated as a town in 1834 and as a city in 1945. Pop. (1961) 43,639. Manufactured products include paper, textiles, chemicals, lumber, furniture and castings. (F. G. R.)

**CORNWALLIS, CHARLES CORNWALLIS**, 1st MARQUESS (1738–1805), British general and statesman, whose most

important service of a long and distinguished career was his term as governor general of India (1786–93), was born in London on Dec. 31, 1738, the eldest son of the 1st Earl Cornwallis (1700–62). He entered the army in 1757, serving in Germany during the Seven Years' War. After 1765 he took some part in politics, and was a firm opponent of the policy of taxation of the American colonies; despite this he went to America as major general in 1776, becoming second-in-command the next year. He was the best of the English generals in America, gaining some victories against the colonists. His southern expedition of 1780–81 began successfully, but on Oct. 19, 1781, he was forced to surrender at Yorktown, and the English cause was irretrievably lost. The defeat did little damage to his reputation in England; he was several times offered the post of governor general in India, and finally accepted it in 1786 on condition that the powers of the office were enlarged.

Cornwallis' government in India was notable for a series of administrative reforms, culminating in the set of regulations of 1793 known as the Cornwallis code (see INDIA-PAKISTAN, SUBCONTINENT OF: History). His reforms were mainly based on the work of others, but their comprehensiveness and the smoothness with which they were effected were due to his tact and determination. The changes in the administration of justice and of the revenue have been criticized, especially the permanent revenue settlement for Bengal which Cornwallis recommended against the advice of experts. But his reform of the civil service introduced a spirit of disinterested administration in India, and the connection between commerce and government was finally broken. The aggression of Tipu Sahib forced Cornwallis to contravene the official policy of nonintervention in native states, and make an alliance with the Marathas and the nizam of the Deccan. In 1791 Cornwallis personally took command of the forces against Tipu, and by a successful campaign in which Bangalore was captured and Seringapatam besieged, he forced Tipu to make peace.

Cornwallis returned to England in 1793, received a marquessate and was made master general of the ordnance with cabinet rank. He was viceroy of Ireland from 1798 to 1801, and ended the serious rebellion of 1798, proclaiming a general amnesty and defeating the French army of invasion. He strongly supported William Pitt's policy of union, and his popularity with both Roman Catholics and Orangemen helped carry it in Ireland. When George III refused to grant Roman Catholic emancipation in 1801, Cornwallis resigned. He was appointed plenipotentiary to negotiate the peace of Amiens in 1801. In 1805 he reluctantly returned to India to replace Lord Wellesley, but he died at Ghazipur on Oct. 5, 1805.

**CORNWALLIS, SIR WILLIAM** (1744–1819), British admiral who, as commander of the channel fleet, 1803–06, maintained the vital blockade of Brest against Napoleon, was born in Suffolk on Feb. 25, 1744, son of the 1st Earl Cornwallis. He entered the navy at the age of 11 and was promoted captain at 22. During the American Revolution he served in the West Indies, taking part in the battles of Grenada (1779) and St. Kitts (1782). At the victory of the Saints off Dominica in 1782 he was critical of the conduct of Adm. George Rodney. In 1788 Cornwallis was sent as commodore to India, where his brother was governor general, and took part in the war against Tipu Sahib, being promoted admiral in 1793. Two years later he conducted a withdrawing action off Brest, in the face of a superior force, with the greatest skill, his 4 ships of the line being attacked by 12 under Adm. L. T. Villaret de Joyeuse. His most important service was when he succeeded Lord St. Vincent in command of the channel fleet blockading Brest in 1801, and again from 1803 to 1806, when he retired. These were the years of peril from the threat of Napoleon's invasion, and upon the close blockade of Brest in all weathers depended the safety of Great Britain. Cornwallis carried out his duty with great resolution, using Ushant as his rendezvous and keeping an inshore squadron to watch the French fleet under Comte Ganteaume. After Sir Robert Calder's action with

Adm. P. C. de Villeneuve on July 22, 1805, the former fell back on Cornwallis' fleet, but when this was reinforced by Nelson's ships after the chase was given up, Cornwallis sent Calder south again in order to prevent Villeneuve coming out of Corunna. Napoleon criticized this division of the main fleet as foolish, but Villeneuve never dared attack the fleet to the north of him and retired to Cádiz. Because of this, the invasion scheme collapsed. Cornwallis retired in 1806 and died in Hampshire on July 5, 1819.

Nelson, who was his lifelong friend, called Cornwallis "a gallant and good officer." He was reserved in manner, but popular with his men who invented many nicknames for him such as "Billy Go-tight" and "Billy Blue," because of his persistence in flying the Blue Peter flag to make sail, and "Coachee" or "Mr. Whip," from his florid complexion.

See G. Cornwallis-West, *The Life and Letters of Admiral Cornwallis* (1927); *The Blockade of Brest*, ed. by J. Leyland, Navy Records Society (1899). (C. C. L.)

**CORNYSHE, WILLIAM** (d. 1523), English composer, actor and favourite court musician of Henry VIII, came from a family closely connected with the Chapel Royal; an older William Cornyshe (d. 1502), possibly his father, was the first master of the choristers at Westminster abbey (1479-91). The younger William was actively associated with the production of court pageants, in which the boy choristers took part, from at least 1501, and in 1509 he succeeded William Newark as master of the children of the Chapel Royal. Under the young and pleasure-loving Henry VIII he continued to devise and perform in plays, masques and pageants. He accompanied the court to the continent on at least two occasions, being responsible for the English performances at the Field of Cloth of Gold (1520). He died in Oct. 1523.

Cornyshe's compositions show an outstanding lyrical gift allied to great versatility, equally at home in the elaborate counterpoint of Mass and votive antiphon and in the more pithy but no less subtle style in which he set the poems of John Skelton and others.

See J. Stevens, *Music and Poetry in the early Tudor Court* (1961). (J. J. N.)

**CORO**, the capital and principal city of Falcón state, Venezuela, is located on the Paraguaná peninsula near the isthmus which connects the peninsula and the mainland. Pop. (1950) 29,341; (1961) 44,757. The city is 105 ft. above sea level. Its climate is hot—mean temperature 83° F.—but not unhealthy. Coro is connected by rail and highway with its port, La Vela (pop., 1950, 2,086), located 7 mi. E.N.E. on the Caribbean. There is a modern airport, and highways give ready access to the heavily populated regions of the nation. Irrigation helps to make agriculture profitable in the surrounding region. Tobacco, coffee, cocoa and castor beans are among the leading products. Soap, shoes and cigars are manufactured on a limited scale. The city is noted for the hammocks manufactured there. There are salt deposits and coal mines in the vicinity. Development of oil refineries on the peninsula have served to make Coro an important commercial centre.

Coro was founded in 1527 by Juan de Ampués (Ampies) as part of a plan of the Spanish crown to suppress slave hunting in the area. Its original name was Santa Ana de Coriana, the latter part of the name being derived from the Coros Indians who inhabited the area. The settlement became the chief factory of the Welsers, the German banking house to which Charles V mortgaged western Venezuela in 1528. The Welsers retained control until 1546 and under them Coro became the centre of departure for numerous expeditions in search of Eldorado (q.v.).

The bishopric of Coro, the first in Venezuela (1531), was transferred to Caracas in 1581. The city was sacked by English pirates in 1567. Coro is celebrated in Venezuelan history as the scene of the first attempt, in Aug. 1806, by Francisco de Miranda, "the precursor of independence," to free the country from Spanish domination. Coro has many churches, including the oldest in Venezuela, and other historic monuments. (J. J. J.)

**COROLLARY.** The word *corollarium*, which meant in classical Latin a gratuity, appears in late Latin philosophical writings with the meaning of an additional inference or consequence.

The word *corollary* is in common use in English with approximately this latter meaning.

In mathematics, a corollary in the strict sense is a proposition which was incidentally proved in the course of proving another proposition, and for which therefore no separate proof is required. However, mathematical writers now generally use the term more loosely to denote any consequence of an existing theorem (or existing proof) which is sufficiently obvious that in practice no proof need be stated for it, or at most a very brief proof.

For example, in elementary geometry, after it has been shown that when two sides of a triangle are equal the opposite angles are equal, it may be inferred as a corollary that if a triangle has all three sides equal, then all three of its angles are equal.

Euclid's *Elements* states no corollaries; the modern examples of corollaries of Euclidean propositions have been added by editors of, or commentators on, the *Elements*. See MATHEMATICS, FOUNDATIONS OF. (A. O. C.)

**COROMANDEL COAST**, a name formerly applied officially and later in a historical sense to the eastern seaboard of India approximately from Cape Calimere northward to the mouth of the Krishna river. The shore, which is low, has no good natural harbours and is at all times beaten by a heavy sea. Madras, about halfway along the coast, has been provided with an artificial harbour at great cost. The northeast monsoon, which lasts from October until April, is violent for the first months. From April till October hot southerly winds blow by day; at night the heat is tempered by sea breezes. The name Coromandel is said to be derived from Cholanandal, the *mandal* or region of the Chola dynasty. (L. D. S.)

**CORONA.** During the few minutes of totality of an eclipse of the sun there is seen surrounding it a halo, pearly white in colour, of irregular shape but roughly circular in form, about twice the size of the sun, with faint streamers extending several solar diameters from the limb of the sun. This is the solar corona. Although the phenomenon becomes perceptible only at the instant when the glaring light from the sun's disk is cut off by the dark moon, the corona must be supposed to be permanently surrounding the sun. Since Bernard Lyot's invention of the coronagraph, certain features of the corona can be observed and studied without an eclipse.

**Forms and Changes.**—Through an approximately circular bright inner corona more or less extensive streamers proceed in a roughly radial direction; near the north and south poles of the sun the long streamers give place to shorter, plumelike rays the "polar brushes." The forms observed can be classified into two main types occurring alternately: at times of minimum sunspot activity the polar brushes are short, and the long streamers tend to approach the direction of the equatorial plane; at times of maximum sunspot activity the polar rays are longer and the streamers show less preference for the equatorial plane, making the corona more circular in form. Over activity centres on the solar surface the inner corona often exhibits regions of excessive brightness and an intricate, archlike structure associated with the structure of underlying prominences. On the whole, the coronal phenomena show a close connection with the other phenomena adherent to the 11-year cycle of solar activity, and the general shape of the corona is in conformity with the rise and fall in latitude of sunspots and prominences in the solar cycle.

From this description it is evident that the corona is subject to considerable variation. Although no changes have been noticed during the short time of totality of an eclipse, observations with the coronagraph extended over longer periods reveal continuous change and movement in the inner corona, especially over disturbed areas on the sun. The duration of recognizable details is found to vary from about one hour to several weeks, the average lifetime of a streamer being one or two days. It should be noted that the apparent variations of the corona are a combination of real changes and the effect of a rotation. A statistical study of intensity distributions along the sun's limb clearly indicates a correlation of distributions observed at opposite limbs with an interval of 14 days, which means that the corona follows the solar rotation. (M. Waldmeier). This has

BY COURTESY OF (LEFT) VERKES OBSERVATORY; (RIGHT) LICE OBSERVATORY

SOLAR CORONA: (LEFT) AT TIME OF MINIMUM SUNSPOT ACTIVITY; (RIGHT) AT TIME OF MAXIMUM SUNSPOT ACTIVITY

been confirmed by the observation of a small difference in wave length (Doppler shift) of lines in the coronal spectrum when measured alternately at the east and the west limb of the sun.

When discussing the forms and brightness of the corona, it should be remembered that, because of its extremely low density, the corona is completely transparent and, consequently, the light observed in any one direction is integrated from all different depths along the line of sight. In general, it is impossible to derive the shape of the corona in space from the appearance in projection which is observed.

**Radiation.**—The total amount of visible light emitted by the corona is approximately one-half that of the full moon, or one-millionth that of the sun, as shown by fairly consistent measurements at later eclipses. It is probably subject to variations, although the unavoidable uncertainty of the observations prevents definite conclusions. More accurate are the measurements of the relative brightness of different parts of the corona, for which various formulas have been proposed, usually expressing the intensity as a function of the distance from the centre. The intensity falls off rapidly near the limb, corresponding to a high inverse power of the distance; farther outward the decrease becomes gradually slower, approaching a value corresponding to the inverse 2.5th power of the distance. Generally, however, the brightness at the same distance from the limb is considerably greater near the equator than near the poles. In any case, with regard to the complex structure of the corona, any intensity formula assuming a spherically symmetrical distribution will give only a rough approximation. It was found by Erik Edlund in 1851 that the coronal light is partly polarized, the plane of polarization being in every point perpendicular to the sun's limb. Observations have shown that the degree of polarization is independent of the wave length of the light and that, after an increase from the limb outward, it reaches a maximum at a distance of about one-third of the sun's diameter and then slowly decreases outward. The maximum polarization is nearly 50% in the equatorial direction but considerably less at the poles.

**The Spectrum.**—The main part of the coronal light shows a continuous spectrum and the same distribution of intensity in different colours as sunlight. In the inner regions of the corona, however, the dark Fraunhofer lines, typical for the solar spectrum, are not present. A faint, broad depression in the violet part

of the spectrum, where a large number of strong Fraunhofer lines should occur, suggests that these lines are effaced through some process by which each individual line is spread out over a wide range, covering perhaps 60 Å (W. Grotrian). Farther outward from the limb, from a distance of about one-fourth of the sun's diameter, the Fraunhofer lines gradually become visible and the spectrum of the outer parts of the corona exactly resembles the solar spectrum, except for a slightly reduced contrast in the dark lines. It is remarkable that these lines, as soon as they are visible at all, are quite sharp; the absence of any transition stages in the behaviour of the Fraunhofer lines indicates a superposition of two quite different components in the formation of the corona.

Superposed on the continuous spectrum of the inner corona are a small number of comparatively faint emission lines, of which the strongest is a green line with the wave length 5303 Å, discovered at the eclipse of 1869. These bright lines contribute less than 2% of the visible coronal light and have no perceptible effect on the colour of the corona. Coronagraphic observations have extended knowledge of these lines, especially in the infrared. The table gives the data for the principal lines, a few faint or doubtful ones having been excluded. The intensities of the lines, though on the whole proportional to the intensity of the continuous light on which they appear, show larger fluctuations, and the intensity distribution around the limb or in radial direction may differ considerably for different lines. This is clearly shown on eclipse photographs taken with a slitless spectrograph, in which the corona is imaged separately in the light of each individual bright line. In particular, the two bright lines in the visible region, the green and the red line, which are both caused by iron in different stages of ionization, show conspicuously different distributions, which may be explained as the result of differences in the temperature and density of the coronal gas.

The origin of the coronal lines has been the subject of much speculation. They have finally been identified (Grotrian, B. Edlén) with radiations from atoms of iron, nickel, calcium and a few other common elements, all very highly ionized. The green line, for instance, is emitted by iron atoms which have lost 13 electrons, or one-half the number normally contained in the iron atom. The lines are moreover of the "forbidden" type, owing their appearance to the low density of the coronal gas, and are in that respect analogous to the nebular lines. The energies required to produce the various stages of ionization show a good correlation with the empirical classification of the lines according to their observed intensities in different parts of the corona.

**Physical Interpretation.**—Few astronomical phenomena have been so difficult to explain and therefore so open to speculation as the sun's corona. The basis for a consistent interpretation has been greatly improved, however, by advances from both the theoretical and observational side; e.g., the identification of the origin of the bright coronal lines and, particularly, the solution of the problem of observing the corona without an eclipse. Continuous records of events in the inner corona are obtained by means of coronagraphs at several high-altitude observatories. At the same time the eclipse observations retain their full interest since many features, especially the outer corona, are still inaccessible without a total eclipse.

**The Dust Halo and the Real Corona.**—The conspicuous change of the spectrum and of other properties of the coronal radiation with the distance from the sun is interpreted as the effect of a superposition of two fundamentally different phenomena. The real corona, a luminous, extreme extension of the solar atmosphere, which shows its typical radiation in the inner regions of the corona, is seen through a halo of solar light diffracted by dust particles in the space between the sun and the earth. This dust halo is responsible for the Fraunhofer component of the coronal radiation, which contributes to the total intensity with an increasing percentage outward from the sun. Because of vaporization by the sun's heat, the space within a distance of, say, five solar diameters, which contains the real corona, is certainly free from any diffracting dust particles. The two components of the corona, therefore, although apparently mixed, need not have any direct physical connection.

The Bright-Line Spectrum of the Corona

Wave length in angstrom units	Element; stage of ionization	Wave length in angstrom units	Element; stage of ionization
3328		5302.86 (strong)	Iron XIV
3388.1 (strong)	Calcium XII		Calcium XV
3454.1	Iron XIII	5694.42	Iron X
3601.0		6374.51 (strong)	Iron XI
3986.9	Nickel XVI	6701.83	Nickel XV
4086.3	Iron XI	7059.62	Iron XV
4231.4	Calcium XIII	7891.94 (strong)	Iron XI
4567	Nickel XII	8024.21	Nickel XV
5116.03	Nickel XIII	10746.80 (strong)	Iron XIII
		10797.95 (strong)	Iron XIII

The dust-halo theory was more soundly established through the recognition of the predominance of diffraction over reflection in this particular case of light scattering (H. C. van de Hulst, C. W. Allen). The theory permits conclusions regarding the size of the particles and the average density of matter in interplanetary space consistent with the observed frequency of meteorites and seems to explain the zodiacal light as an extension of the same diffraction phenomenon.

The main part of the light from the inner corona, showing a strong polarization and a continuous spectrum with the same colour distribution as the sun, has long been recognized as solar light scattered by free electrons (K. Schwarzschild, 1906). The electrons, because of their small masses, will have great thermal velocities, about 50 times greater than hydrogen atoms at the same temperature, and the Doppler effect caused by these high random velocities would cause a considerable widening of the Fraunhofer lines in the scattering process. The lines would be smoothed out and eventually vanish completely at a high enough temperature, as observed.

According to this interpretation nearly 99% of the coronal light is directly borrowed from the sun, one part being scattered by interplanetary dust and the other part, the main constituent of the inner corona, being scattered by the free electrons in a gaseous envelope, a coronal atmosphere of the sun.

**Density.**—That the coronal gas must be extremely thin was early concluded from the observation of comets passing at high speed through large distances in the inner corona without suffering any change or retardation. From the observed intensity of the corona and the known scattering coefficient of the electron it is possible to compute the number of electrons per cubic centimetre. As the negative charge of the electrons must be compensated by an equal amount of positive charge, the coronal gas must contain nearly the same number of protons, hydrogen being certainly the most abundant element and completely ionized at the coronal temperature.

In this way the density of the corona in its densest parts near the sun's limb is found to be approximately one-million-millionth that of air at atmospheric pressure.

With regard to the finer structures of the corona, the arches and streamers and the large-scale motions, one must remember that the coronal matter, as consisting exclusively of electrically charged particles, is strictly guided in its motions by the lines of magnetic force as soon as a magnetic field of any appreciable strength is present. The detailed coronal structures are therefore likely to reproduce the structures of the magnetic field around the sun.

Conclusions regarding the chemical composition can be drawn from the relative intensities of the bright coronal lines, giving the relative abundances of various metals, and from the intensity of the lines as compared with the intensity of the electron scattering, giving essentially the ratio of metals to hydrogen. There is no indication of any striking difference in composition between the coronal gas and the chromosphere.

**Temperature.**—The physical explanation of the coronal atmosphere presents unsurmountable difficulties if—as was long assumed as a matter of course—the temperature of the gas were of the same order as the surface temperature of the sun, about  $6,000^{\circ}\text{C}$ . Observed facts require for a logical explanation a much higher temperature. In the first place, the enormous extension of the corona can be understood only if the gravitational forces are balanced by great thermal velocities of the gas particles, corresponding to a temperature between  $1,000,000^{\circ}\text{C}$ . and  $2,000,000^{\circ}\text{C}$ . Contrary to older belief, the radiation pressure is not likely to play any role in this problem since the free particles, which are the main constituents of the coronal gas, do not absorb light. A similar temperature is derived from the observed profiles of the bright coronal lines, which are about one angstrom wide, and from a quantitative discussion of the disappearance of the Fraunhofer lines in the electron-scattering process. The high ionization of the metal atoms, as well as the remarkable fact that no hydrogen lines are observed in the coronal spectrum, also finds a plausible explanation at a temperature of the order of  $1,000,000^{\circ}\text{C}$ . The observed intensity of solar radio noise, which has been shown to

originate in the corona, permits of similar conclusions regarding the coronal temperature.

Though the discovery of the high temperature of the coronal gas provides a consistent physical picture of the phenomenon, the mechanism by which the corona is heated remains a subject for speculation. Because of the low density the quantity of energy required to maintain the temperature is only a small fraction of the total solar radiation, the difficulty being to find a mechanism producing the required quality of energy. Particles of interstellar matter would be accelerated in the sun's gravitational field to velocities high enough to produce the observed high temperature, but it is questionable whether the density of interstellar matter is high enough to cover the thermal losses of the corona. Furthermore, the shape and detailed structure of the corona, being directly associated with the solar activity, would rather point to an energy source in the sun itself. It has been suggested that mechanical energy of the turbulent motions in the photosphere, which show as granulation, could be transformed into a special kind of wave motion, transported upward and absorbed in the corona by a mechanism which ultimately is a Joule heating through electric currents (Hannes Alfvén).

**Extreme Ultraviolet Radiation.**—As already mentioned, the main part of the light from the corona is scattered sunlight, while the specific radiation of the coronal gas, the bright lines, contribute only 1% or 2%. In the visible wave-length region the specific coronal radiation thus amounts only to about one-hundred-millionth of the radiation from the sun. Because of the great difference in temperature between the corona and the photosphere, however, the ratio of coronal to solar radiation will increase enormously as the wave length of the radiation decreases. For a rough calculation one may assume that the coronal gas radiates, with a certain dilution factor, as a "black body" at a temperature of  $1,000,000^{\circ}\text{C}$ . On this assumption one finds that the amounts of radiation emitted from the sun and from the coronal gas become equal in the wave-length region around  $1000\text{ \AA}$ , and that for still shorter wave lengths the photospheric intensity soon drops to a negligible amount in comparison with the coronal intensity. Spectra of the integrated sunlight taken from above the earth's atmosphere by means of rocket-borne spectrographs actually show in consistency with this picture, that the continuous light from the sun's disk fades away below  $2000\text{ \AA}$  and gradually gives place to a bright-line spectrum characteristic of highly ionized matter. The extreme ultraviolet radiation is completely absorbed in the earth's upper atmosphere, producing ionization. It is likely that the ionized layers, which reflect radio waves, are at least partly caused by coronal radiation. Coronagraphic observations have therefore become of interest as a means of predicting conditions for radio communications.

**CORONADO, FRANCISCO VÁZQUEZ DE** (1510-1554), Spanish explorer of the American southwest. He accompanied Viceroy Antonio de Mendoza to New Spain in 1535 as friend and protégé and soon gained distinction in subduing rebellious Indians. He was made a member of the town council of Mexico City, June 1538, and in August became acting governor of the province of New Galicia, an appointment which was confirmed the next year. Fray Marcos de Niza's exploration of 1539 into the northern interior, telling of the rich Seven Cities of Cibola—the present Zuñi, N.M.—led Mendoza to send a great expedition under Coronado to conquer them. Accompanied by more than 300 Spanish cavalry and 1,000 Indian allies, plus Fray Marcos, Coronado conquered the Seven Cities in July 1540, but found no riches. He sent Pedro de Tovar to explore the Hopi villages. García López de Cárdenas the Grand canyon country, and Hernando de Alvarado the Rio Grande, where Coronado followed and set up headquarters at Tiguex, the centre of a populated area north of modern Albuquerque. Here the army spent the winter of 1540-41, conquered some rebellious pueblos and reconnoitered at

surrounding country. At Pecos the Spaniards found an Indian who told of a country farther east more wonderful than the Seven Cities. News of this land, called Quivira, led Coronado to explore the Great Plains in the summer of 1541. When he reached Palo Duro canyon in Texas, bewildered by the vastness of the country, he sent the main force back to Tiguex, while he led 30 horsemen to the great bend of the Arkansas river in Kansas in search of the mythical kingdom. But Quivira, inhabited by Wichita Indians, was not rich in gold or silver, and Coronado returned to Tiguex dispirited. The following winter he suffered a blow on the head while jousting. When he recovered, the expedition left New Mexico, returning the way it had come.

For his conduct of the expedition, Coronado underwent an official inspection, as the law required, and was indicted, but the *audiencia* of Mexico, in Feb. 1546, declared him innocent. He was not so fortunate in the official *residencia* of his governorship, for which he was indicted and fined on several charges, and lost some of the Indians he held in *encomienda*. But he continued to serve as a member of the council of Mexico City and retained the friendship of Viceroy Mendoza, being one of the chief witnesses for his defense in the official *residencia*. Coronado died on Sept. 22, 1554.

See Herbert E. Bolton, *Coronado, Knight of Pueblos and Plains* (1949). (G. P. Hd.)

**CORONARY THROMBOSIS** (CORONARY OCCLUSION or MYOCARDIAL INFARCTION), a condition in which a plug or clot forms in a branch of the coronary arteries, which supply blood to the heart muscle itself. See ARTERIES, DISEASES OF; HEART, DISEASES AND DEFECTS OF.

**CORONATION**, a solemnity whereby sovereigns are inaugurated in their office. From the earliest historical times in Europe the king or chieftain, on his election, was inaugurated by some public ceremony. He might be raised upon a shield, placed upon a sacred stone, presented with a spear, or invested with a distinctive robe or headdress. Whatever the particular ceremony might be, however, it was essential that it should take place in the sight of the assembled people. When Europe became Christian, though some of the older customs lingered on, they were grafted onto a religious service derived from the biblical accounts of the anointing of Saul and David by Samuel. Once the biblical precedent of anointing with oil had been introduced into western Europe the whole idea of kingship was altered. The ruler attained a new status. Whatever might be its exact significance—and this was disputed throughout the middle ages—it could not be denied that the anointed person was a man in some sense set apart with a special relationship both to God and to his people. By virtue of the unction he was peculiarly fitted to receive the crown and other insignia, and it was almost inevitable that he should receive them from the clergy by whom he had been anointed. In western Europe the first king specifically recorded as having been anointed was Vamba, the Visigothic king of Toledo, in 672.

**England.**—The English coronation service traces its descent from the *ordo* drawn up by Archbishop Dunstan for the coronation of King Edgar at Bath in 973. This was based on two earlier models, known as the Leofric and Egbert services, which appear to date from the early 10th century. Neither of them seems to have originated in England, but they were used by Dunstan, who added many of the coronation ceremonies in use on the continent at the time. In the Edgar *ordo* all the essential features of a modern coronation appear in a primitive form—the oath, the anointing, the investiture, the enthronement and the homage. It was subsequently often revised, notably in the 12th century under Archbishop Anselm and again in the 14th (the *Liber Regalis*). English took the place of Latin after the Reformation, but the coronation remained a service of election, of confirmation of the people's choice, of self-dedication and of consecration. There is no doubt, too, that it was deliberately molded on the service for the consecration of a bishop. Also, after 1689, reverting to much older usage, both the coronation service and the service for the consecration of a bishop were incorporated in the communion service. The English coronation service now consists of four distinct parts, one leading on to the other and forming a coherent whole:

(1) the introduction, consisting of the entry, the recognition and the oath; (2) the consecration of the sovereign by anointing; (3) the investiture of the anointed sovereign with the royal robes and insignia culminating with the crown; and (4) the enthronization and homage followed by the communion service. The recognition is historically the ratification by the people of the former ceremony of election in Westminster hall, when the sovereign was placed on the king's bench in the sight of all. At the recognition the people are asked if they wish the service to proceed, and it is made clear that the monarchy is based upon the people's will and consent. Assured of this, the archbishop can proceed to administer the oath, which ensures that the sovereign will respect and govern according to the laws and will uphold the Protestant Reformed religion of England and Scotland and preserve the Church of England. The recognition and the oath form the contract between the sovereign and the people and are the foundations of the whole service. The archbishop can now consecrate the sovereign, who is thereupon anointed on the palms of both hands, the breast and the crown of the head. This is the central moment of the service, for it is only when the sovereign has been anointed that investiture with the royal robes and insignia can follow. Finally the crown of St. Edward is placed on the head of the sovereign, who then moves from the coronation chair to the throne and is lifted up into it by the archbishop, bishops and other peers. Historically, this is the moment when the sovereign enters into his inheritance, and for the first time is clearly seen by all to have been duly anointed, invested and crowned. The homage of his subjects naturally follows. When the lords spiritual and lords temporal have paid their homage there is a threefold acclamation by which the people present, representing the third estate, complete the act of homage and thus end the solemnity of the sovereign's coronation. If there is a queen consort, her coronation follows at this point. Otherwise the communion service is resumed at the offertory and proceeds to its close.

For many centuries the English coronation service was followed by a banquet in Westminster hall. During the course of this the king's champion in full armour entered the hall on horseback and, throwing down his gauntlet, three times challenged anyone to deny the sovereign's right to the crown. The office of king's champion is attached to the manor of Scrivelsby, and has been held since the 14th century by the Dymoke family as owners of the manor. The challenge was the most picturesque of several personal services, of which some are still performed during the coronation ceremonies. The banquet was last held, and the challenge made, at the coronation of George IV in 1821. The king's champion, however, now has the duty of bearing the standard of England during the coronation service.

**France.**—The Frankish kings originally began their reign by being raised on a shield and acclaimed. The legend of the anointing of Clovis (see below) refers to his baptism, not to his accession. Pepin, first king of the Carolingian dynasty, partly in order to sanctify his superseding the Merovingian kings, was twice anointed, first possibly by St. Boniface, then by Pope Stephen III (II). With his successors in the 9th century unction became an established part of the ceremonial. Eventually the form of coronation in France, in its general features, closely resembled the English coronation service on which, it is believed, it was originally based. From the 11th century onward it customarily took place at Reims. The unction was given, first on the top of the head in the form of a cross, on the breast, between the shoulders and at the bending and joints of both arms. Then, standing up, the king was vested in the dalmatic, tunic and royal robe, all of purple velvet, sprinkled with fleurs-de-lis of gold, and representing, it was said, the three orders of subdeacon, deacon and priest. Kneeling again, the king was anointed in the palms of the hands, after which the gloves, ring and sceptre were delivered. The peers were then summoned by name to come near and assist, and the archbishop of Reims, taking the so-called crown of Charlemagne from the altar, set it on the king's head. After this the enthronement and the showing of the king to the people took place. Mass was then said, and at its conclusion the king communicated in both kinds.

In connection with the anointing of the kings of France there was a legend that the Holy Dove had descended from heaven, bearing a vessel (afterward called the Sainte Ampoule), containing holy oil, and had placed it on the altar for the coronation of Clovis. A drop of oil from the Sainte Ampoule mixed with chrism was afterward used for anointing the kings of France. Similarly, the chrism was introduced into English coronations, for the first time probably at the coronation of Edward II. To rival the French story another miracle was related that the Virgin Mary had appeared to Thomas Becket and had given him a vessel with holy oil, which at some future period was to be used for the sacring of the English king. A full account of this miracle, and the subsequent finding of the vessel, is contained in a letter written in 1318 by Pope John XXII to Edward II. The chrism was used in addition to the holy oil. The king was first anointed with the oil and then signed on the head with the chrism. In consequence of the use of chrism the kings of England and France were thought to be able to cure scrofula, hence called king's evil (*q.v.*), by the imposition of their hands.

Napoleon I in 1804, having brought Pope Pius VII to Paris to anoint him in the cathedral of Notre Dame as emperor of the French, placed the new imperial crown on his own head.

**The Holy Roman Emperors and the German Kings.**—The custom whereby the Holy Roman emperors were crowned by the popes dates from the coronation of Charlemagne on Christmas Day 800 (*see* HOLY ROMAN EMPIRE for this controversial incident). The anointing of the emperor by the pope was instituted at the coronation of Louis I the Pious in 816. The last Holy Roman emperor to go to Rome for coronation was Frederick III in 1452; Charles V, however, was crowned by the pope but at Bologna, not in Rome.

Otto I, Otto II and Otto III were crowned as German kings at Aachen (where Charlemagne had been crowned king of the Franks), and from Henry III's to Ferdinand I's time Aachen was the customary place for the German coronation, being recognized as such by the Golden Bull (1356). Charles V's successor Ferdinand I, however, who had been crowned German king at Aachen in 1531, was crowned as Holy Roman "emperor elect" in 1558 at Frankfurt am Main, and thenceforward Frankfurt was the place of coronation for the emperors till the dissolution of the Holy Roman empire. After preparatory ceremonies and prayers the emperor was consecrated and anointed, then clothed in the imperial and pontifical robes and presented with the regalia and the sword of Charlemagne and finally crowned by the three archbishop-electors jointly.

After the dissolution of the Holy Roman empire, the later Habsburg emperors of Austria were crowned only as kings of Hungary in Buda.

**Hungary.**—The crown of St. Stephen was first used for the coronation of Stephen I (*q.v.*) of Hungary in A.D. 1000 or 1001. Thenceforward the place of coronation varied, the chief places being Székesfehérvár, the oldest royal residence; the coronation church in Buda; and, during the Turkish occupation of central Hungary, Pozsony (Bratislava). The crown was always placed on the king's head by the archbishop of Esztergom, the primate of Hungary.

**Poland.**—The first Polish coronation took place in 1025, at the Gniezno cathedral, when Boleslaw I was crowned king of Poland. From 1320 to 1734, all coronations were held at the Wawel cathedral in Cracow, except that of Stanislaw I Leszczyński in Warsaw in 1705. The bishop of Cracow had the right of placing the crown on the king's head. The last king of Poland, Stanislaw II Poniatowski, was crowned in Warsaw in 1764.

**Russia.**—The first coronation of a Russian tsar (*venchanie na tsarstvo*) took place in Moscow in 1547, when Ivan IV the Terrible was crowned in the Kremlin, at the Uspenski cathedral, with the so-called "Monomakh hat," alleged to have been sent by a Byzantine emperor to Vladimir Monomakh (1113–1125), grand prince of Kiev (this hat is still in the Kremlin, and the workmanship of the original part of the crown appears to be of the 12th or 13th century). The hat was placed on the tsar's head by the patriarch of Moscow, after the anointing. Peter I the Great, how-

ever, assumed the title of emperor (*imperator*) and abolished the patriarchate. Thereafter the coronation ceremony was known as *Koronovaniye imperatorskoye* and was conducted, still at the Uspenski cathedral, by the four Russian metropolitans, those of Moscow, Kiev, Novgorod and St. Petersburg. Uncction remained, but the emperor put the new imperial crown on his own head and also crowned his empress. The first coronation according to the new ceremonial took place in 1724 when Peter I crowned his consort, who as Catherine I succeeded him in 1725.

**Spain.**—During the middle ages in Spain the kings of Asturias, León and Castile were anointed and crowned by a bishop (though Alfonso XI put the crown on his own head). After John I of Castile, however, the ceremony died out and the accession of the Castilian kings was marked simply by an act of acclamation or proclamation in all the cities and towns of the kingdom. In Aragon kings were always anointed and crowned until, with the union of the Spanish kingdoms, the ceremony was replaced by a solemn entry into Madrid.

**Sweden and Norway.**—The kings of Sweden used to be anointed and crowned originally at Uppsala, later by the archbishop of Uppsala in the Storkyrka in Stockholm, those of Norway at Trondheim by the bishop. Gustav V of Sweden, however, and Olaf VI of Norway, dispensed with these ceremonies.

**CORONEA (CORONEIA), BATTLE OF (394 B.C.).** In this battle of the Corinthian War (*see* GREECE: *History*) the Spartan king Agesilaus II was checked by the combined forces of the Thebans, Athenians, Argives and Corinthians, although he was technically victorious. While the offensive by the coalition was being stemmed at the battle of Nemea (*q.v.*), Agesilaus was on his way back overland from Asia Minor to the defense of the homeland, having broken off his campaign against the Persian power on the urgent summons of the ephors. After passing safely through Thessaly and gathering reinforcements, he was faced at the gap of Coronea in Boeotia by the main forces of the coalition. As before at Nemea each right wing overlapped and smashed the opposing left. Agesilaus, however, while the victorious Theban right pressed on to attack the Spartan camp, wheeled his victorious right inward against the Theban centre. Nonetheless the Thebans succeeded in forming a new front to meet this menace and eventually forced their way through to join the rest of their army.

*See* Xenophon, *Hellenica*, iv, 3, 16 *et seq.*

**CORONEL**, Chilean coal mining and shipping centre on the Gulf of Arauco, and seat of Coronel department in Concepción province. The city, pop. (1960) 60,234 (mun.), is located about 18 mi. S. of Concepción, to which it is linked by rail and surfaced highway. The community was founded in 1851 and received city status in 1875. Its growth has reflected the development of coal mines in the vicinity, for Coronel functions as a shipping as well as a commercial centre. Local soft coal production represents about 30% of Chile's output and modern methods of mining and loading coal are employed. The operations extend under the floor of the gulf. Company-owned pine and eucalyptus plantations supply mine and construction timber and some lumber for commerce. There are foundries and shops and planned company housing areas. The city of Coronel has a congested and spontaneous appearance. (J. T.)

**CORONEL, BATTLE OF**, a notable German naval victory of World War I, was fought on Nov. 1, 1914. Evidence had reached the British admiralty early in Oct. 1914 that the East Asiatic squadron of the German navy, under Vice-Adm. Graf Maximilian von Spee, was moving toward the west coast of South America, where its presence would threaten vital supply-lines from Chile to Great Britain. Rear-Adm. Sir Christopher Cradock, with

a hastily assembled squadron consisting of the outdated cruisers "Good Hope" and "Monmouth," the light cruiser "Glasgow" and the armed merchantman "Otranto," was instructed to "search and protect trade" along the Chilean coast. With the exception of "Glasgow," these ships were manned largely by old reservists and partly trained boys. At 4:25 P.M. on Nov. 1, the British met the German squadron, consisting of the first-class cruisers "Scharnhorst" and "Gneisenau," and the light cruisers "Leipzig," "Dresden" and "Nürnberg," all manned by long-service complements. Cradock signaled the attack two hours later, but his situation was already hopeless, for in addition to superior strength, range and speed, von Spee had secured the shoreward position, so that twilight cloaked the German ships while the British were silhouetted against the setting sun. Within an hour the flagship "Good Hope" blew up with the loss of her entire complement, "Monmouth" was burning fiercely, "Otranto" had withdrawn and only "Glasgow" could continue the battle. "Monmouth's" captain ordered "Glasgow" to make her escape, and just before 9 P.M. "Monmouth," having refused to surrender, was sunk with all hands by "Nürnberg."

Von Spee won his victory at negligible cost, but the British were fully revenged five weeks later, in the battle of the Falkland Islands (q.v.).

**CORONER**, a public official whose principal duty in modern times is to inquire, with the help of a jury, into the cause of any death that appears to be due to unnatural causes.

The office originated in England and was first referred to as *custos placitorum* ("keeper of pleas") in s. 20 of the Articles of Eyre (1194). It is believed by some, however, that the office was first mentioned in the Charters of Privilege, granted by King Aethelstan to St. John of Beverly in the year 925. The name was originally known as "crownor" or "coronator," derived from *corona*, meaning crown. The coroner's dignity and power were second only to the king. He was originally charged with the duty of safeguarding the king's property and served as a check on the sheriff in the royal interest. Other powers already obsolescent were expressly taken away by s. 44 of the Coroner's act of 1887, which, interestingly enough, re-enacted the provision of Magna Carta (1215) that prohibited both sheriff and coroner from holding pleas of the crown. The medieval coroner was no longer a militant figure.

The office was always elective, the appointment being made by the freeholders of the county assembled in the county court. The first Statute of Westminster (1275) enacted that none but lawful and discrete knights should be chosen as coroners. Afterward, lands of the value of £20 (the qualification of knighthood) were considered sufficient.

The Coroners Amendment act, 1926, requires that a coroner shall be a barrister, solicitor or legally qualified medical practitioner of not less than five years standing in his profession, no property qualification being required. The practice of the London county council is to appoint persons possessing both legal and medical qualifications.

The judges of the high court of justice are ex officio sovereign coroners; they may (but, in fact, do not) exercise their jurisdiction in any part of the realm. Under the 1926 act, the duties of a coroner are limited to an inquest into the cause of all deaths occurring within his district by violent or unnatural means or from some unknown cause, or of the death of anyone who has died in prison or under such circumstances as to require an inquest in accord with other legislation. The coroner must view the body, but the jury need not. If any person is found guilty of murder, manslaughter or infanticide, the coroner commits him to trial, but in practice he seldom has to do this, since s. 20(1) of the act provides that if the coroner is informed before the jury has given its verdict that some person has been charged with any of these crimes, he shall adjourn the inquest until after the conclusion of the criminal proceedings.

By the City of London Fire Inquests act, 1888, the coroner for the city of London holds inquests in cases of loss or injury by fire in the city of London and its liberties situated in the county of Middlesex. In Scotland, the duties of a coroner are performed by an officer called a procurator fiscal. In Canada, all coroners are appointed by order in council, signed by the lieutenant governor of the province. As a judge of a court of record, he is not liable to civil action for anything done by him in his judicial capacity if he acts indiscreetly or erroneously.

**United States.**—In the United States the office is usually elective, but in some states it may be appointive. In a few states the coroner's staff is composed of a number of employees representing varied scientific departments of medicine, such as pathology, toxicology and chemistry. In some jurisdictions, the coroner has police power equal to that of the sheriff in all cases where the latter is incapacitated or has a personal interest in the case before him. The coroner of a county may issue a warrant for the arrest of persons who have caused the death of another by criminal means, and the warrant may be executed in any part of the state. In some states, pathologists are coroners and must be graduate physicians; in others, a layman may be authorized as coroner, with the power to employ a physician to conduct the autopsy. The only person who can definitely give the cause of death is the coroner or one deputized to perform the duties of his office. Unless this is the case, it is usually impossible to establish the *corpus delicti*, i.e., the basic facts necessary for the commission of the crime.

The coroner's office is operated differently in many states. About half of the states have a coroner's system; in some of the others the sheriff or the justice of the peace takes over, while in others the coroner's office has been replaced by a medical examiner. There are also other arrangements, including a combination system with both a coroner and a justice of the peace having jurisdiction. In most states, the power to issue warrants is confined to homicide cases, but in such cases the coroner possesses all the powers of a magistrate to take testimony and issue warrants. (J. L. Do.)

**COROT, JEAN BAPTISTE CAMILLE** (1796–1875), one of the most notable French landscape painters of the 19th century, was born in Paris on July 16, 1796. His father was a draper, his mother a very successful milliner of Swiss origin. Educated at the Lycée at Rouen, Corot dutifully followed his father's trade for some years, but in 1822 was allowed to leave commercial life and study painting. He rewarded the financial support that his parents gave him with complete dedication to his art.

As a young man Corot sought to establish himself in the tradition of neo-classical landscape painting exemplified by P. H. de Valenciennes (1750–1819). He had met and had lessons from two of Valenciennes' disciples, A. E. Michallon (1796–1822) and J. V. Bertin (1775–1842), but it was the actual experience of going to Rome in the autumn of 1825 that was decisive in the formation of Corot's style. He stayed until 1829, painting the city and the Campagna, and also making excursions to Naples and Venice.

Following the custom of his day, Corot spent these years making small oil sketches which he planned to use later in large landscapes painted in the studio according to classical rules of composition. He was building up a repertory of forms, and regarded these sketches as documents, not as finished works of art, never exhibiting them. They are among the first French paintings done entirely out-of-doors, and are the most personal (and now the most admired) part of Corot's work; they show an immediate response to nature, a readiness to experiment with the oil medium and a sensuality in the handling of paint that he was soon to lose entirely.

On his return to Paris in 1829 Corot set about painting in earnest the large landscape compositions that he regularly showed at the Salon. Most of them included small figures, which sometimes give a flavour of the Bible—"Hagar in the Desert" (Salon, 1835), "Christ in the Garden of Olives" (Salon, 1849), "Saint Sebastian" (Salon, 1853); of literature—"Homer and the Shepherds" (Salon, 1845), "Macbeth and the Witches" (Salon, 1859; Wallace collection, London), "Dante and Virgil" (Salon, 1859; Boston, Mass.); of antiquity—"Diana Surprised by Actaeon"

ARCHIVES PHOTOGRAPHIQUES

"CHARTRES CATHEDRAL" BY COROT, 1830. IN THE LOUVRE

(Salon, 1836), "Biblis" (Salon, 1875); or of an ideal rustic life—"Souvenir de Mortefontaine" (Salon, 1864; Louvre, Paris).

Corot traveled widely in search of landscape material, returning to Italy in 1834 and in 1843, visiting Avignon and the south of France in 1836, Switzerland in 1842, Holland in 1854 and London in 1862. He made regular summer tours, collecting material that he worked up in his studio in Paris during the winter. Among his favourite regions were the forest of Fontainebleau, Brittany, the Normandy coast, the family property at Ville d'Avry near Paris, and, later in life, Arras and Douai in the north of France.

Corot also painted straightforward, almost topographical landscapes, like the "Chartres Cathedral" (1830), the "Château de Rosny" (1840), or the "Belfry at Douai" (1871), all of which are in the Louvre. There is little development, but the particular quality of sweet romantic melancholy that he cultivated in the Salon pictures soon permeated his work. His self-consciously poetic and idyllic landscapes with their sensitive tonal effects and delicate range of silvery colours won Corot great popularity, but these pearly gray mist-enveloped twilight scenes now appear exceedingly artificial and formula-built by the side of Impressionist landscape painting. The portraits and figure pieces of the last 20 years of Corot's life, as "L'Atelier" (several versions, c. 1865) and "La Perle" (1868-70, Louvre), are much less artificial, and witness to Corot's innate classicism and his absolute mastery of tonal painting.

Corot never lacked admirers and his work was well received in the salons. He was rewarded with medals, purchases by the state and by the emperor, and with membership in the Legion of Honour. He was friendly with the slightly younger painters of the Barbizon school, and his influence can be seen in the painting of A. Chintreuil, S. Lépine and Camille Pissarro. A dedicated man with simple tastes, he never married; he had a reputation for saintliness and great charity when he died in Paris on Feb. 22, 1875. ## CORPORATE INCOME TAX: see CORPORATION TAX.

**CORPORATE STATE.** Corporativism or the corporate state is a view of society that sees the community as composed of diverse economic or functional groups rather than of discrete individuals; in theory it would make the basic governmental unit the group or corporate body rather than the individual. Members of the central governing body would represent specific functional groups (estates) rather than localities. In actual practice, however, as put into effect by various fascist regimes between World Wars I and II, the so-called corporate state usually reflected the will of a dictator rather than the adjusted interests of groups. It provided an ideological cloak for a policy of comprehensive control of all industry and labour by the government and ruling party.

Corporativism was an important feature of Italian Fascism (see FASCISM) and continued to play a role in the dictatorship of Salazar in Portugal. In Germany's national socialism (*q.v.*) the corresponding pattern of bureaucratic centralism was embodied in the German Labour Front, set up under the slogan of "coordination" (*Gleichschaltung*). The idea also played a considerable role in the Fascist ideology of Austria and its *Heimwehr*.

**Theory.**—Historically, the ideology of the corporate state harks back to ideas developed by Christian conservatives in reaction to what they considered the excessive individualism of the French revolutionary ideology. To the allegedly mechanistic notions of the Industrial Revolution they would oppose the organic concepts of what they maintained was the corporate character of medieval society. These ideas found authoritative expression in an encyclical of Leo XIII, *Rerum Novarum* (1891), and were reaffirmed in *Quadragesimo Anno* (1931) by Pius XI.

It deserves attention, however, that much of this thought was radically at variance with actual Fascist practice, because of the latter's bureaucratic centralism, for medieval corporativism was built upon the autonomy of the constituent corporate bodies. It constructed a multicentred organic whole in terms of the self-sufficiency (*Eigenständigkeit*) of the constituent groups. Thus the medieval town was seen by its latter-day admirers and theorists as a co-operative union of guilds, whereas the Fascist corporate state entailed the total eclipse of such autonomy by the radical extension of governmental control and direction to all spheres of social life and activity.

**Italy.**—Behind this murky façade of ideology, the Fascists and National Socialists erected their ruthlessly totalitarian apparatus of economic controls. Indeed, the corporate organization evolved out of the peculiar Fascist unions, or syndicates, unions which were actually developed in competition with the free socialist unions and gained ascendancy after the Fascists had seized power. Their original socialist syndicalism (*q.v.*) was soon superseded. It was replaced by corporations which comprised both employers and employees who would, for the sake of "unity," operate under the direction and control of the state, *i.e.*, the bureaucracy. The corporative system was initiated in Italy by the Charter of Labour, on April 21, 1927, adopted by the Grand Council of Fascism as a party measure. It was afterward transformed into a governmental system. Under it, workers lost all rights and privileges for which their unions had fought. The key passages of the charter asserted that "since the private organization of production is a function of national concern, the organizer of the enterprise is responsible to the state for the direction of production. . . . The employee is . . . an active collaborator in the enterprise, the direction of which belongs to the employer who bears responsibility for it."

The charter contained some commendable social welfare features, such as health protection, scholarships for the children and insurance against disability, illness and old age, as well as governmental control of minimum wages, holidays and vocational education. But these provisions ought not to deceive anyone about the basic totalitarian concept; strikes, it was asserted, "are criminal offenses," and both labour and management were placed at the dictator's bidding. However, as a result of the partnership of government and industry, organized through the Institution for Reconstruction, management was recompensed for its loss of effect-

tive control by a scheme which guaranteed profits and thus eliminated risk, whereas free labour was turned into industrial serfdom.

**Germany.**—The German copy of this scheme, adorned by some turgid metaphysics about the "community" of the factory, also was embodied in a Charter of Labour, Jan. 20, 1934. It went further than its Italian prototype in sanctioning compulsory work assignments, and outdid it by describing the control of leisure time activities as "strength through joy" rather than merely prosaic *dopolavoro* ("after work") activities. By applying the "leadership principle" throughout the organization, it revealed the true nature of the corporate state: the total bureaucratization of the entire economy under one-party government. See also NATIONAL SOCIALISM.

**CORPORATION**, a group of persons authorized by law to act as a unit. It may be a public body, as is commonly the case in Great Britain, or a business enterprise, as is usually the case in the United States. It may also be an educational institution such as a college or university, a labour union or a charitable foundation. A public corporation is an agency of government established to carry on certain functions of a business nature, such as the Reconstruction Finance corporation in the U.S. The present article deals with the business corporation in the U.S., first discussing its history and then its legal aspects. For coverage of related British practice see COMPANY.

A corporation is a fictitious legal person and as such has a corporate name, followed by the word "Incorporated" or the abbreviation "Inc." In this name the corporation may sue and be sued, and may hold and transfer property. In the eyes of the law, therefore, the group has an existence independent of its individual members. It may long outlive any one of them. This continuity of existence gives the corporate form of business enterprise a clear advantage over a partnership (*q.v.*), which comes to an end with the death of a partner.

Business corporations divide their capital stock into shares. Shares are often purchased by a large number of investors, each subscribing a relatively small sum. This divisibility of the corporation's capital facilitates the accumulation of the large sums required by modern industry. Another factor facilitating capital accumulation is the limited liability of shareholders for the debts of the corporation. In the event of bankruptcy they may lose their investments but all their other property is safe from attachment.

Such advantages go far to explain the predominance of the corporate form in modern American economic life, particularly in manufacturing. But they have little relevance to the period of its origins in either Europe or the United States. Indeed, to understand how the business corporation came to be used in the United States, and the purposes it served, requires some attention to its European background.

This article is divided into the following sections:

#### I. Historical Development

##### A. Early History

1. European Background
2. Colonial Period
3. Early Years of Independence
4. Internal Improvements
5. Opposition to Privileged Corporations

##### B. Emergence of the Business Corporation

1. Growth of Urban Markets
2. The Corporation and the 14th Amendment
3. Advances in Technology
4. Competitive Position
5. Business Combinations

##### C. Trusts and Antitrust Legislation

1. Holding Company
2. Form of Corporate Organization
3. Sherman Antitrust Act
4. Merger Movement
5. Policies of Theodore Roosevelt
6. FTC and Clayton Acts
7. Mergers in the 1920s

8. Antitrust Enforcement
9. Conglomerate Mergers
10. Pros and Cons of Antitrust Laws

#### II. Corporation Law

1. Organization of Stock Corporations
2. Powers of the Corporation; Shareholders; Directors and Officers
3. Voting Rights and Voting Control
4. Fiduciary Obligations of Directors and Officers
5. Legal Obligations of Promoters and Controlling Shareholders
6. Shareholders' Suits
7. Types of Corporate Securities
8. New Issues of Shares
9. Shareholders' Individual Liability
10. Dividends and Other Distributions
11. Amendment of Corporate Charters
12. Merger and Consolidation
13. Dissolution, Bankruptcy and Reorganization
14. Other Types of Business and Private Corporations

#### I. HISTORICAL DEVELOPMENT

##### A. EARLY HISTORY

**1. European Background.**—Corporations existed long before they were used for business purposes. Some scholars trace their origins to such groups as the family, clan or tribe, which are found in the most primitive societies. The more complex societies of the ancient world developed towns, guilds and colonies; churches and universities appeared in medieval Europe. The notion that the legal authority of the state is necessary for the formation of corporate bodies is also very old. For cases where the state did not create the corporate group, or no record of its origins could be found, there arose the theory that some associations might come into existence by prescription derived from custom. Both Roman and English law made use of this theory. It is safe to say, however, that prescriptive corporations were confined to forms of association older than the business corporation.

In England, the authority of the crown was essential from the first for the formation of the business corporation. After the revolution of 1688 the authority of parliament was necessary in any case involving a grant of monopoly or other special privilege. In the 16th and 17th centuries it was business corporations in the form of great trading companies that made possible the English voyages of discovery, commerce and colonization. These culminated in the early 17th century in the first permanent English settlements in Virginia and New England.

To suggest that the Virginia company or Massachusetts Bay company was created primarily as a profit-making association would be highly misleading. It is true that the great trading and colonizing companies did seek profits. It is also true that they divided their capital into transferable shares to ease the problem of raising capital. But the achievement of neither of these objectives required that a corporation be formed. These ends might have been realized by utilizing the unincorporated joint stock company, a form of enterprise that was currently in use in some branches of English overseas trade. In the eyes of the law these unincorporated companies were large partnerships, but this fact did not prevent them from amassing and managing large capital sums. The basic reason the government granted charters of incorporation to some joint stock companies was to encourage private capital to promote ends that were regarded as public or semi-public in nature.

The public policies of many European governments between the 16th and later 18th centuries were often those of mercantilistic writers, advisers and officials who sought by means of vigorous governmental action to promote the internal unity, power and self-sufficiency of the state (see MERCANTILE SYSTEM). Charters of incorporation that bestowed exclusive privileges upon a group of joint-stock investors were looked upon as means to these ends. Within spheres of operation defined by their charters the great trading corporations of the 16th and 17th centuries were usually granted a commercial monopoly and the power to enforce it by means of regulations bearing the force of law. These business corporations of the early modern period were far more than mere instrumentalities of private profit. The charters they received bestowed upon them a semi-public status.

**2. Colonial Period.**—These conclusions, as we shall see, are fundamental to an understanding of the nature of most of the corporations created during the long colonial period of American history (1607-1783) and for nearly 50 years thereafter. As the colonies increased in population corporations sprang up in the form of towns, boroughs and cities. Before the end of the colonial period a large number of corporations had also been created for ecclesiastical, educational and charitable purposes. But business corporations were few in number and relatively unimportant. In the 17th century these included the water company of Boston and William Penn's Free Society of Traders in Pennsylvania. During the 18th century there appeared the New London trading society, two groups of wharf proprietors (in New Haven and Boston), three small water companies in Rhode Island, and a mutual fire insurance society in Philadelphia. The local and public service character of these corporations is self-evident.

One main reason so few business corporations developed in colonial America was that the spheres of activity in which they were required were subject to the disposition of crown and parliament rather than of local colonial governments. Under the unwritten British constitution, the terms of which were to be vigorously debated during the years of crisis between 1764 and 1776, internal matters alone were subject to the control of colonial governments; imperial concerns belonged to the jurisdiction of London. Colonists had therefore nothing to do with those larger interests of empire which required for their development both large sums of capital and a delegation of governmental powers. England looked to the East India company and other chartered joint-stock companies for the development of imperial commercial interests. Prevailing mercantilist doctrines did not favour encouraging colonists to be self-sufficient. Colonies were looked upon as sources of supply for raw materials to be manufactured in the mother country and as markets for manufactured goods.

The objects of concern on the part of the colonial governments were therefore small and local in nature, seldom requiring services or facilities beyond the tax-yielding capacities of local communities. While the size of both foreign and domestic markets expanded during the 18th century the capital required for their supply was easily amassed by individual proprietors or partnerships. Unincorporated joint-stock companies raised by transferable shares the capital required for mining, manufacturing and land speculation. Commercial banks did not exist in the colonies, although merchants performed some banking functions. Marine insurance was almost always obtained from English underwriters. Travel and shipping by sea reduced the need for north-south roads, while the existence of east-west rivers that were navigable to the fall line, together with British discouragement of settlement west of the Appalachians, narrowed the need for improved east-west routes of travel.

**3. Early Years of Independence.**—Many elements of this situation began to change soon after the achievement of independence. Between 1776 and 1800 about 250,000 migrants settled west of the mountains, or in the mountain valleys, thus increasing sharply the need for improved routes. State governments created more than 300 business corporations between the end of the American Revolution and 1801, and the provision of inland navigation, turnpikes and toll bridges was the purpose of two-thirds of them. No longer debarred from trade with the far east, American merchants expanded both the geographic area and volume of their foreign commerce, particularly after the outbreak of European war in 1793 opened up the commercial world to their neutral vessels. Risks of loss increased correspondingly and English underwriters were usually not disposed to be generous with the claims of American neutrals. To meet this problem the states chartered a number of American insurance companies between 1786 and 1800.

The expanded volume of trade created at the same time a need for the short-term credit facilities of commercial banks, with the result that no fewer than 34 were incorporated between 1781 and 1801 (27 of them between 1790 and 1801). Commercial expansion increased the size of cities and increased their needs for public services. Thirty-two corporations for the supply of water

and four for the erection of docks were created between 1795 and 1801. The need of cities for protection against fire losses was reflected in the organization of nearly a dozen mutual fire insurance companies between 1786 and 1800. The large majority of the 32 insurance companies chartered during this same period, moreover, were privileged to write either fire or marine insurance.

The predominance of highway and other public-service associations among the joint-stock companies chartered in the early national period points clearly to the expanded sphere of responsibility on the part of American political communities following the Revolution. These business corporations were no more exclusively profit-seeking associations than were the chartered joint-stock companies with which the English had pioneered in the settlement of America. They were, in fact, quasi-public agencies of the state. "Be it enacted by the Senate and House of Representatives in General Court assembled," reads a Massachusetts statute of 1818, that the following named individuals "hereby are constituted a corporation and *body politic*" for the purpose of erecting a flour mill. As "*bodies politic*" these corporations, like their predecessors, were accorded certain exclusive privileges in order to encourage the devotion of scarce private capital to public ends. Among these privileges were monopoly rights of way, tax exemption, the right of eminent domain and the right, granted to many nonbanking corporations, to facilitate the raising of needed capital by engaging in banking operations and holding lotteries.

At the same time banks and insurance companies were incorporated to meet the needs created by the growth of American business enterprise. Except for fire insurance, these institutions served the business component of the community chiefly, although by no means exclusively. One bank, it should be noted, received its charter from the national government rather than from the states. The Bank of the United States, chartered by congress in 1791 for a period of 20 years, was a notable public-service institution. While four-fifths of its capital stock of \$10,000,000 was subscribed by private sources, and only one-fifth by the federal government, the institution served important public purposes by acting as a depository for federal funds, making short-term loans to the federal government, transferring federal funds from one part of the country to another and helping maintain a sound and uniform banknote currency. The bank owed much to Alexander Hamilton's view that public fiscal ends could best be promoted by enlisting private capital in their support. On the whole, however, the character of most early American corporations reflected the very old view that charters should be issued only to those associations formed to serve the public interest.

During approximately the first third of the 19th century public service continued to dominate the purposes for which business corporations were chartered. This is evident both from the economic and other circumstances of the time and from the kinds of corporations that received charters. Capital was scarce in relation to the needs of a population that was growing rapidly; settling increasingly in cities and moving westward. The American people had numbered only about 4,000,000 when the first census was taken in 1790; by 1830 the total was nearly 13,000,000. Urban centres had totaled 24 to 1790; by 1830 their number was 90. Corporations to supply water, construct bridges, operate ferries and steamboats and provide insurance and banking facilities received charters in increasing numbers from state governments. It is difficult, moreover, to exclude from the category of public service the manufacturing corporations chartered in the early years of the century. During the troubled years preceding and during the War of 1812 the stream of imports of manufactured goods declined to a trickle. In this situation some state governments appear to have adopted the view that the chartering of domestic manufacturing associations was a matter of patriotism. Between 1808 and 1815 New York issued more charters (165) to joint-stock companies engaged in manufacturing than to all public utilities combined (164). This phenomenon appears not to have reoccurred in any other period before the American Civil War.

**4. Internal Improvements.**—The most enduring and costly

requirement in the first half of the 19th century lay in the field known to contemporaries as that of "internal improvements." These were turnpikes, canals, railroads and other transportation facilities, required in both the settled areas of the east and in the growing west. Lured by cheap land and constantly expanding urban markets for agricultural produce, settlers poured westward in a torrent following the War of 1812. The resulting need to bind the newly settled areas of the west to the economy of the seaboard states became the nation's primary economic problem.

Two main obstacles impeded the development of transportation routes. Despite the fact that foreign trade had made possible important accumulations of commercial capital, serving for example as the chief means of producing about a half-dozen millionaires by 1815, over-all supplies of capital were scarce. Perhaps equally important was the fact that local supplies of capital were meagre along the lines where turnpikes, canals and railroads were projected to run. The second main impediment lay in the developmental nature of internal-improvements projects. Few could promise quick returns on investment capital. Indeed, almost all projects looked for most of their returns to the settlement and economic activity that their own construction was designed to promote. Profits would necessarily be deferred and widely diffused.

The chartering of public-service corporations was one answer to these obstacles and to an extraordinarily keen public interest in internal improvements. State governments granted tax exemptions and other privileges to corporations engaged in improving transportation facilities. They also floated bond issues to raise funds to subscribe to the stocks of the enterprises and in many cases joined with local governments in granting outright gifts of money. Not private capital alone but public as well—federal, state and local—joined hands in a characteristically mixed enterprise to create the "social overhead capital" that was so essential to the development of the nation's resources.

**5. Opposition to Privileged Corporations.**—These halcyon days were not destined to endure. As capital accumulated, the line between public interest and private advantage became more sharply visible to critics of the privileges enjoyed by corporations. It was certainly true that abuse crept easily into the prevailing system of obtaining charters. With a few exceptions, such as New York and Connecticut, which in 1811 and 1817 respectively passed general laws permitting qualified incorporators of certain kinds of manufacturing concerns to apply to the secretary of state for a charter, incorporation by special act of the state legislature was everywhere the rule before the late 1830s. Lobbying expenses, delay and bribery often attended appeals to state legislatures for acts of incorporation. It was to the advantages which incorporators under this system were often able to wring from lawmakers that Andrew Jackson referred when he complained in a presidential message of the multitudes of corporations with exclusive privileges which businessmen had succeeded in obtaining in the different states. Jackson, like Jefferson before him, was a man of fundamentally agrarian temperament who deplored the rapid economic and social changes which were subordinating older and simpler modes of life to urban business values.

Agrarian critics were not alone among the opponents of specially privileged corporations, particularly banking corporations. The supporters of President Jackson included businessmen as well as farmers. These business critics of existing modes of procuring charters wished to put an end to special privilege; they wanted the profit-making opportunities presented by the burgeoning economy opened on equal terms to all. Jackson's secretary of the treasury, Roger B. Taney, well typifies this attitude in his remark: "There is perhaps no business which yields a profit so certain and liberal as the business of banking and exchange; and it is proper that it should be open, as far as practicable, to the most free competition and its advantages shared by all classes of society." Under President Jackson's leadership in the early 1830s men of agrarian and entrepreneurial persuasion joined in a successful assault on the second Bank of the United States. Successor to the first bank, which had passed out of existence in 1811, the second bank (1816-1836) had affronted both rural philosophies and the urban economic interests of state banks in its

successful management under Nicholas Biddle of the nation's currency and credit. By curtailing loan expansion on the part of state-chartered institutions Biddle had restricted their profits. With the central regulatory agency gone after 1834 (when the federal government ceased making deposits in the bank), the number of state-chartered banks rose from 506 in 1834 to 901 in 1840. At the outbreak of the Civil War they numbered 1,601.

It was Taney who, as treasury secretary, had presided over the beginning of the bank's end by removing federal deposits from it. Four years later, as chief justice of the U.S. supreme court, he struck an even more telling blow in favour of free, competitive enterprise. In the *Charles River Bridge* case (1837) Taney severely modified an earlier ruling by chief Justice John Marshall concerning the sanctity of contracts. The issue involved was the claim by a Massachusetts bridge company that its corporate charter gave it exclusive, monopolistic business rights by implication. Taney rejected the contention, holding that no corporate charter could confer implied powers beyond the specific terms of the grant. His decision thus freed new businesses from the fear of claims of monopoly on the part of older corporations with ambiguously phrased charters.

These attacks upon enterprise restrictions had two important consequences. First was Michigan's passage of a free banking act in 1837 that served as an important precedent for similar laws in other states. More than a half-dozen states, moreover, passed general incorporation laws before the Civil War. But while an increasing number of charters were taken out under general laws the lure of special advantages from special acts led most incorporators to prefer the older method until about 1875. The second important consequence was a tendency to seek charters of incorporation in expanding fields of enterprise. Paralleling this development was a shift of emphasis in the business corporation from public service to private profit.

The attacks upon enterprise restrictions coincided with the gathering strength of forces pushing the nation's economy to new levels of achievement. At the centre of these forces were continued population growth together with increases in national income which more than kept pace with the expanding population. In consequence, an American nation whose numbers rose from 17,000,000 in 1840 to 23,000,000 in 1850 and to 31,500,000 in 1860 constituted an effective domestic market for both agricultural and industrial goods. New miles of railroad track knit together the producing and consuming centres of expanding regional markets. To meet the rising demand required a gradual abandonment of older methods of production. Farmers first worked longer hours, then added to their output by using such mechanical aids as threshers, mowers and reapers. Industrial output was increasingly expanded by means of the factory system of production. Appearing first in cotton textiles, then spreading to carpet manufacture and to the making of arms, clocks, watches and sewing machines, factory methods developed rapidly after 1840. The clearest indication of the rise of factories is the great increase in the rate of urban growth in the two decades before the Civil War. The number of cities rose from 131 in 1840 to 236 in 1850 and to 392 in 1860. By 1860 the factory system was rapidly becoming important everywhere in industry.

## B. EMERGENCE OF THE BUSINESS CORPORATION

A rapid increase in charters granted in the 1850s heralded the dawn of the age of the business corporation. Yet it was only the dawn. Industrial techniques that required large capital investment were of recent origin in important fields and made their way but slowly among constituent firms. Not until after 1835 did expensive metallic textile machinery come into general use. Not until 1839 were the first successful coke-smelting furnaces built in the United States. As late as 1869 nearly half the mechanical power used in manufacturing came from water wheels and turbines rather than from steam engines. But it is not so much the first appearance of new techniques as their spread that matters in economic growth. Imitation is more important than innovation. Among the important explanations of imitative lag must be set not only the inertia of traditional and less-costly

methods. Ignorance also counted for much, as did the scarcity of technical journals, trained engineers and cost-accounting techniques. The gradual overcoming of these obstacles contributed in the post-Civil War years to a wider dissemination of mechanized production methods. But on the eve of that conflict individual proprietorships and partnerships rather than corporations were able to amass the capital required for the control of most of the resources devoted to manufacturing.

The second half of the 19th century is marked by three principal developments in the life of the business corporation. First, there was a phenomenal expansion in the use of the corporate form, especially in such fields as iron and steel, nonferrous metals, textiles, chemicals and liquor. Indeed, manufacturing corporations constituted a large percentage of all charters granted each year after 1875. Second, there was a notable growth in size of the individual unit of enterprise. Finally, during the 1880s there began such remarkable changes in administrative organization as to justify the conclusion of a leading student of these developments, Alfred D. Chandler, Jr., that the decade saw the emergence of the modern corporation.

While these three major developments point to marked growth in the economic role of the corporation it should be made plain that partnerships and sole proprietorships continued to play important roles in economic life. Paralleling the growth of corporations were the towering figures of individual businessmen, and it is they, rather than the corporation, who left their stamp upon these years. In the forefront of industrial expansion stood such men as Andrew Carnegie (iron and steel), Gustavus Swift (meat packing), John D. Rockefeller (oil), James J. Hill (railroads) and J. P. Morgan (investment banking), men whose business organizations during at least the first flush of their rapid growth often took the form of partnerships. Called variously "robber barons" and "giants in the earth" their exploits make up the last great saga of economic individualism in the U.S. In the main their later careers and those of their successors were engulfed by the collectivism of the corporate age.

**1. Growth of Urban Markets.**—What mainly accounted for the expanded use of the corporate form was the rise of a national urban market. Railroads forged the transcontinental links of this market. In 1869 the first transcontinental line was completed, and from 1870 to 1914 railroad builders laid an astounding total of 200,000 mi. of track, nearly half of it west of the Mississippi river. The spreading railroad net made possible the settlement of the farmer's last frontier. During the half-century following the Civil War farmers occupied more land than in all the previous years of American history. The agricultural output of new and fertile lands, increased by wider use of machinery and scientific techniques, quickened the growth of such older cities as New York, Philadelphia, Cincinnati, Cleveland and St. Louis and helped create such new ones as Chicago, Indianapolis, Atlanta, Kansas City, Dallas, Minneapolis and St. Paul. Between 1840 and 1880 the urban proportion of the total population rose from 11% to 28%; between 1880 and 1900, from 28% to 40%.

This rapid urban growth intensified the demand for the products of industries manufacturing consumer goods. Between 1880 and 1907 incorporation for the manufacture of food and kindred products, textile mill products and other consumer goods bulked large among total incorporations. Indeed, it was the consumer-goods industries, the researches of Alfred D. Chandler, Jr., show, that were the first to become dominated by great business enterprises. By the beginning of the 20th century, however, a swelling number of companies were engaged in the manufacture of machinery for the use of producers rather than of goods for consumers or farmers.

**2. The Corporation and the 14th Amendment.**—Paralleling the rise of a national urban market were noneconomic forces which both paved the way for corporate expansion and augmented its scale. Following the Jacksonian attack on privileged corporations several states, as noted above, had in the 1840s adopted constitutional provisions requiring incorporation under general laws. By 1875 these provisions had become so common that special charters were virtually a thing of the past for most fields of

enterprise in most states of the union. Since the new system opened incorporation on equal terms to all, it was considered more democratic than the old. Incorporation was no longer looked upon as a privilege but as a right. Symptomatic of the change in the climate of values, and itself a great spur to incorporation, was the U.S. supreme court's decision in the case of *Santa Clara County v. Southern Pacific Railroad* (1886) stating for the first time that the word "person" in the 14th amendment included corporations in some instances. Since the 14th amendment specified that no "person" might be deprived of life, liberty or property without "due process of law" this and subsequent decisions protected corporations from discriminatory taxation by the states. Not surprisingly, the corporation developed a personality. According to Thomas C. Cochran the great company came to be personified as a kind of frontier folk hero, with the successful corporation executive a symbol of American achievement.

Incorporation came to be used in large numbers of cases in which it would be difficult to justify resort to it in terms of large capital needs. Indeed, since about 1875 it has generally been true that small incorporations (less than \$100,000) have constituted a large percentage of total charters granted, medium-sized incorporations (less than \$1,000,000) a much smaller percentage, and large incorporations the smallest of all. A major exception to this generalization is supplied by periods of intense incorporating activity, such, for example, as Colorado experienced during a mining boom in 1895-96. The predominance of incorporation among firms of relatively small authorized capital stock can often be explained on the ground that many small companies have grown big without abandoning their original charters. Many large companies, that is to say, were first incorporated as small ones. But whether or not originally incorporated as a large firm, the great modern corporation dominates the field of American industry, and justifies emphasis upon the reasons for its rise.

**3. Advances in Technology.**—The spread of a changing technology is one of the chief factors in the rise of big business. The use of heavy machinery and larger plants required firms of larger size. Despite the fact that the number of manufacturing establishments remained virtually unchanged during the 1870s the amount of capital invested in them rose by two-thirds and the value of industrial output by more than half. And since these increased capital costs could most conveniently be raised by dividing the total sums into small shares for sale to numerous investors, technological change also abetted the rise of the corporation.

Technological change, however, is not self-generating. Given a society possessing the necessary knowledge and skills, and with no legal or entrepreneurial obstacles to innovation, technological advance depends primarily upon two conditions. The first of these, scarcity of labour, has been a perennial, if sometimes overstated, factor in American economic growth. The second is an increased demand for goods. Substantial gains in the real earnings of labour and in incomes per person indicate that both factors were operative during the second half of the 19th century. Increased mechanization and an enlarged scale of production were in the nature of responses to them. What happened was that the mass demand of a national urban market called forth mass production, together with the technological and other means necessary to its achievement.

**4. Competitive Position.**—Turning out large quantities of standardized goods, the large firm achieved efficiencies that lowered the unit cost of production. In competition with small firms, the large corporation had many advantages. It could hire a more highly skilled management, could market its goods more effectively and could finance itself more cheaply by using profits retained in the business. At the same time, the large firm also had to bear high overhead costs on its fixed capital investment in plant and machinery. This erosion of capital by depreciation, interest and obsolescence charges helped create a portentous situation, for railroads as well as large-scale manufacturers. In times of falling prices business managers tended to maintain production and compete vigorously for sales at any price in preference to allowing their heavily burdened plants to remain idle. Sales at low

prices provided some income, which was better than none at all. Given a long period of falling prices, this was a situation in which not only smaller firms but also larger ones of lesser efficiency could have little hope for survival.

The years from 1873 to 1896 constitute precisely such a period of long-term falling prices. In this setting the American business arena became a jungle in which many failed to survive the bitterly competitive price wars and ruthlessly sharp business practices. With prices (and railroad rates) being forced down close to cost, it became evident that two paths to survival might be open. Ways would have to be found to (1) keep prices up and (2) keep costs down. Both involved some form of combination. To keep prices up businessmen entered into "horizontal" combinations of varying kinds with their competitors in the same stage of production or distribution. "Combinations, syndicates, trusts," Andrew Carnegie frankly admitted, "They are willing to try anything."

Vertical combination (integration), on the other hand, did not involve direct restrictions upon competition. Indeed, the firm that practised vertical combination, by bringing under its control the successive stages of production from raw materials to end product, was enabled to compete more vigorously, because the practice lowered marketing and other costs and assured supplies of raw materials.

**5. Business Combinations.**—The first attempt at combination among competitors usually took the form of a "gentlemen's agreement." In the main, this was a verbal agreement to set and maintain prices, although it sometimes also included common policies regarding cash discounts and other trade practices. When the object of combination could not readily be agreed upon in an informal manner business managers favoured a written contractual agreement known as the "pool." Pools were formed for various purposes. Sometimes, as in a patent pool, the use of a new device or process was thereby confined to a restricted group. Sometimes, as in a profits pool, profits were paid into a central fund and then divided up on the basis of the percentage of total sales in a given period. Probably the main use of the pool was as a device to restrict output. This was effected by dividing the total market and assigning each producer a portion of it. Sometimes division was made on the basis of output, with each producer being assigned the sale of a given number of units; sometimes a territorial division was made, in which case each was assigned a designated sales area. While pools had not been unknown even before the Civil War, they were comparatively little used until after 1875. In the 1880s and 1890s they were to be found in such important industries as those making whiskey, salt, meat products, explosives, steel rails, structural steel, cast-iron pipe and tobacco products. Comparable to the European cartel (*q.v.*), the pool differed from its counterpart in this key respect: under the English common law, recognized in every U.S. state except Louisiana, it was regarded as an illegal, and hence unenforceable, restraint of trade.

Both gentlemen's agreements and pools may be said to have "worked," if only temporarily. Indeed, there can be no doubt that both forms of combination continue in use in the United States. But these relatively loose forms of collusion had serious disadvantages. For one thing, to the degree that they were successful in raising prices and achieving a "monopoly" profit, they encouraged new firms to enter the field. Furthermore, one of the main aims of collusion was the maintenance of prices during periods of deflation. But it was precisely at such times that the temptation to violate agreements was strongest. A firm might exceed its assigned output or sell in forbidden territory, in which case other pool members had no legal way of compelling it to adhere to its agreement. Some better system was required, and business managers found it in various closer-knit arrangements.

#### C. TRUSTS AND ANTITRUST LEGISLATION

The first and most famous of these was worked out in the depression-ridden 1870s by C. T. Dodd, a business associate of a man who was perhaps the shrewdest business manager in a generation of shrewd men. The man was John D. Rockefeller and the

idea was the trust. The device of trusteeship is a very old one, but Rockefeller's Standard Oil company put it to a new use. Employing ruthlessly competitive business practices, Rockefeller and his associates had succeeded during the 1870s in gaining control of more than 90% of the oil-refining capacity of the country. In 1882, three years after they had formed the Standard Oil trust under the laws of Ohio, they induced the stockholders of 40 oil companies to turn their shares over to nine trustees. The trustees thus acquired voting control of the 40 companies. In place of the stock, its former owners received "trust certificates" entitling them to dividends. So profitable did this device prove, and so successful as a means of centralizing control of an entire industry, that it was soon widely imitated. During the 1880s trusts were formed to control production in the tobacco, sugar, whiskey, cotton oil, linseed oil and lead industries.

The fatal defect of the trust form of combination was that the agreements were a matter of public record. Since, in the eyes of common law, conspiracies in restraint of trade or attempts to gain a monopoly were illegal, the prospects of longevity for trusts would not be good once suits were brought against them in state courts. A number of suits were begun in the 1880s, and in consequence of one of them the supreme court of Ohio ordered the Standard Oil company to withdraw from the trust on the ground that it was attempting to create a monopoly. It was clear that some other form of combination would have to be used in place of the trust. The solution to this problem was a form of business organization which some states had previously created by special act.

**1. Holding Company.**—In 1888–89 the state of New Jersey revised its general incorporation laws to allow corporations to purchase and hold the securities of one or more subsidiary corporations. It proved relatively easy for the resulting "holding company" to bring a number of previously independent firms under unified control. It was not necessary even to consult the nonvoting preferred stockholders and bondholders. Indeed, voting common stock often was so widely distributed that it was possible to exercise effective control by purchasing less than 50% of it. New Jersey's Holding Company act proved so successful in bolstering that state's finances with revenues from incorporation fees that other states soon "liberalized" their corporation laws in an effort to induce businesses to seek charters from them. Few state laws at that time required corporations to divulge significant information to the investing public, and it was only after much mulcting of unprotected investors, stock watering and other abuses by large corporations that the states, at about the turn of the century, abandoned their liberal attitudes and began requiring increased publicity.

The widespread legalization of the holding company did more than provide a device enabling competitors to form horizontal combinations (at least until the U.S. supreme court's decision in the *Northern Securities Company* case in 1904); it also gave firms a means of integrating vertically. The nature of the need for some such legal device can more clearly be seen by considering the specific case of the consumer goods industries. Prior to the rise of a national market the individual firm in these industries generally relied upon commission agents for the procurement of its materials, as well as for the sale of finished products whenever markets were located more than a few miles from the factory. Their first reaction to the emergence of a national market was to enter into agreements with firms performing one specific function, such as marketing or distribution. As in the case of early forms of horizontal combination (gentlemen's agreements and pools) these agreements proved hard to enforce, and resources were not effectively utilized. What was needed was a tighter control of the stream of resources than could be provided by a mere federation of firms, as well as a legal form of business organization that would permit operations on a national scale. Men like Gustavus Swift in meat packing, and others with relatively new products, moved toward vertical integration by creating nationwide sales and distributing systems, enlarging their processing facilities, and then building their own purchasing organizations. The holding company provided the necessary legal form, and in

other enterprises this kind of vertical integration followed its adoption.

No matter what the sequence, however, the arrangement of all operations under the control of a single, centralized management raised, in turn, the problem of how to make that control as efficient as possible. This was a problem in business administration, and the successful solution of it produced the modern corporation. The problem had two parts: first, the need for methods to manage operations that were geographically dispersed; second, the need for co-ordination of all operations to the optimum advantage of the firm as a whole. The fulfilling of these needs required not only a clear distinction between functions of the field and headquarters offices but also a careful allocation of responsibilities at both levels.

**2. Form of Corporate Organization.**—The headquarters of business enterprises had been slow in developing. In the early 19th century the typical business figure had been the merchant in foreign trade. His headquarters was his countinghouse, and there he supervised the routine tasks of a bookkeeper and a clerk or two, besides giving thought to investment opportunities by which his house might prosper. Needing no large force of permanent employees, he relied mainly on the services of commission agents. Early 19th-century industrial enterprises similarly purchased their raw materials and sold their finished goods through commission agents, although sometimes they utilized the selling services of wholesalers. Their headquarters, too, were small. Many large textile mills employing hundreds of workers were run with practically no office force at all. As markets expanded from local to regional dimensions, however, some pre-Civil War firms, particularly in the railroad industry, began to departmentalize their headquarters. The vertical integration movement, which was so accentuated by competition in postwar national markets, not only accelerated this process of departmentalization but also obliged businessmen to work out problems of co-ordination between headquarters and field. This the modern corporation proceeded to do by providing a separate administrative department for each major activity: production or purchasing of raw materials, manufacturing, marketing and finance.

At the head of each department was placed a specialist in the activity for which that department was given responsibility. Normally a vice-president, and supreme in his own sphere, he was given a managing director to handle departmental routine. Each vice-president fulfilled two main duties: he had the responsibility for the broader development of his department and he had to co-operate as a member of an executive committee composed of all department heads, together with the president and the chairman of the board of directors. The executive committee, in turn, had three functions. It co-ordinated the various activities of the enterprise, both interdepartmentally and between headquarters and field offices, for the purpose of assuring a steady flow of product from raw materials to ultimate consumer. It made plans for the maintenance and expansion of the enterprise as a whole. And it appraised the performance of the entire organization.

In doing these things, the executive committee came more and more to rely on accounting and statistical information in regard to costs, output, purchases and sales. The extensive operations of the modern corporation thus permitted specialization in the performance of various managerial functions, and specialization usually meant greater proficiency in each of them. Only from such specialization could there have emerged expert accounting techniques that permitted the substitution of scientific procedures for rule-of-thumb methods of operation. The work of Frederick W. Taylor in scientific management, which a number of modern corporations were soon to make use of in their continued drive for cost-reducing efficiencies, was a natural by-product of the trend toward specialization and cost accounting.

The modern corporation, appearing first in the railroad industry in the 1850s and in the consumer goods industries in the 1880s, transformed the leading firms in those industries by the early years of the 20th century. Its first major appearance in industries making goods for producers dates from the 1890s. Combining functional specialization with administrative centralization, it gave

to firms adopting its procedures such competitive advantages as to compel their adoption by other leading firms in the same industry. Smaller companies, unable to compete except in small and specialized markets, tended to be absorbed or forced into bankruptcy. Competitive pressures in national markets thus served as an important factor in company growth, sometimes in conjunction with technological compulsions making for the same end, sometimes independently of them. The upshot was an even greater tendency for national markets to be dominated by a lessening number of large firms.

**3. Sherman Antitrust Act.**—These developments by no means escaped the notice of the general public. Indeed, court actions against trusts, together with newspaper attacks upon them, whipped public opinion to a high pitch of resentment. The very word trust became a synonym for monopoly, and by the mid-1890s about 17 states had passed antitrust laws. Antitrust sentiment was probably strongest in the middle west, with its hard core of embittered farmers, but it was found throughout the country, especially among small businessmen who had been bankrupted by the harsh methods of the trust-builders. Huge increases in agricultural production, without accompanying increases in foreign and domestic demand, had brought low prices to farmers ever since 1869. The prices that farmers had to pay for goods and services, however, did not undergo a comparable decline. In this bleak age for agriculture (it lasted till 1896) high interest charges, high freight and grain storage rates, and high prices for industrial goods induced farmers and their editorial and political spokesmen to lash out against railroads, banks and other middlemen, and against industry generally. Evidence of collusion in the form of trust agreements only increased their burning anger. In this situation, a congress alert to the political strength of agriculture passed, with almost no debate and even less opposition, a law destined to become one of the most controversial in U.S. history, the Sherman Antitrust act of 1890.

The key sentence in the Sherman act was the declaration that, "Every contract, combination in the form of trust or otherwise, or conspiracy in restraint of trade among the several states, or with foreign nations" was illegal. The act went on to say that, "Every person who shall monopolize, or attempt to monopolize, or combine or conspire with any other person or persons to monopolize any part of the trade or commerce among the several states, or with foreign nations, shall be deemed guilty of a misdemeanor . . ." What the sweeping and undefined terms of the act would mean would depend upon their application to specific cases by the federal courts. The act had elevated to statutory form ancient rules of common law against acts in restraint of trade and attempts to monopolize. For example, common law had prohibited forestalling (buying goods outside of town in order to resell them at a higher price) and engrossing (buying large quantities of goods in an effort to establish monopoly control of the market). During the colonial period courts had declared unlawful agreements between associations of employers and employees to restrict output or raise prices. It was clear enough then, that certain kinds of restraints of trade were harmful to the public interest and hence unlawful. One major common law tradition held that only the injurious kind were unlawful. Unfortunately, from the point of view of clarity, a second major tradition maintained that restraints were unlawful whether injurious or not. Senator Sherman himself referred to this dual tradition and also to an expectation shared by some of the leading sponsors of the Sherman act, when he said that the courts must distinguish between "lawful combinations in aid of production and unlawful combinations to prevent competition and in restraint of trade . . . It is the unlawful combinations, tested by the rules of common law and human experience, that is aimed at by this bill." Most congressmen appear to have been more than willing to leave the imprecision of the act to the courts. They had wanted to enact a law so sweeping in its provisions as to render it unenforceable, and hence harmless. What really concerned them was not antitrust legislation at all but a protective tariff, which the farmers opposed. They regarded the Sherman act as a minimum measure of appeasement to the farm group.

Despite the hue and cry against the trusts congress probably reflected the nation's predominant mood of laissez-faire. Until 1903 it was neither willing nor compelled by public opinion to vote the extra funds that would have eased the tasks of antitrust enforcement. National administrations read the times in the same way, for the government brought only 23 cases under the act before 1903. One attorney general, Richard Olney (1893-95), frankly said he had taken the responsibility of not prosecuting because he believed the Sherman act "no good." The U.S. supreme court all but made it a dead letter by ruling in the *E. C. Knight* case (1895) that it was inapplicable to manufacturing because that process was antecedent to commerce and only incidentally involved in it. In the *Addyston Pipe and Steel Company* case of 1899, however, it unanimously ruled that it was the sale and delivery of a product rather than its manufacture that was the material portion of a commercial contract, and that a sale for delivery beyond the state made the transaction a part of interstate commerce.

**4. Merger Movement.**—The *Addyston* decision was also important for other reasons. The case involved price and marketing agreements between the members of a pool of cast-iron pipe manufacturers. When the court declared such agreements void, business managers correctly took this to mean that pools and other forms of loose-knit combinations would be held illegal under the Sherman act. They then proceeded incorrectly to assume the obverse, namely that close-knit combinations would be considered legal. Acting on this assumption they turned with enhanced enthusiasm to a merger movement that was already under way. Probably the *Addyston* decision, therefore, elevated the peak of a giant wave of mergers which came at the turn of the century. When that wave receded it left in its wake the United States Steel company, American Tobacco company, International Harvester company, Du Pont company and other giants of the 20th century. Its effects on the U.S. economy were therefore widespread and enduring.

A merger is a combination into a single firm of two or more previously independent enterprises. There are two ways in which mergers may occur: via consolidation and via acquisition. In the great turn-of-the-century wave the consolidation process brought into existence new firms, but the acquisition process did so only rarely. Consolidation was resorted to when large capital sums appeared to be required, as for example, in the case of U.S. Steel, capitalized at \$1,400,000,000, the first billion-dollar corporation in American history. Acquisition sufficed when the sum needed was not beyond the capital sources of an already extant firm. Most of the mergers in the great wave of 1898-1902 were accomplished by consolidation, and the effect of the *Addyston* decision (1899) may be seen in the number occurring in different years. According to Ralph L. Nelson, in 1895 and 1896, five were consummated each year; the numbers rose to 10 and 26 in 1897 and 1898. Then in 1899 the greatest number in any single year in U.S. history—106—took place. In that year 1,028 previously independent firms disappeared into mergers.

The New York Stock exchange played an important part in facilitating these mergers. The new firms brought into being for the purpose of effecting the mergers had been incorporated as holding companies. Often the technique for gaining control of previously independent firms was to exchange holding company stock for a controlling number of shares in operating companies. Promoters were most likely to initiate consolidations when stock market values were rising, for the prospects of profitable stock sales served as an important inducement to the stockholders in firms to be merged. The state of the stock market was also important when the technique of control involved the purchase of firms for cash, for new capital issues were often required to raise the cash.

The need to raise gigantic sums brought to the foreground of American business men who specialized in the marketing of securities. Unlike the first two post-Civil War decades of manufacturing growth, in which the financing of firm expansion had largely been carried out by industrialists themselves, investment bankers like J. P. Morgan had the leading parts in the merger movement

of the 1890s. Investment bankers had gained valuable experience in huge reorganizations of railroad corporations in the 1880s and early 1890s—reorganizations of capital structures which sought the easing of burdens of fixed charges by such devices as increasing the proportion of stocks, which required no interest payments, to bonds, which regularly required them. Indeed, the marketing of railroad stocks in connection with these reorganizations had developed the New York capital market to a point where it could play an important role in the financing of industrial mergers in the late 1890s.

The prominence of the New York Stock exchange, of investment bankers and of promoters in the great merger movement lent strong support to the hypothesis that the desire for profits from sales of stocks on a rising market had much to do with producing that movement. The desire for scale economies apparently had little to do with it: except in the primary metals industries the overwhelming number of mergers was horizontal in nature rather than vertical. Some of these mergers, however, were followed by the achievement of scale economies from administrative reorganization. Profits from sales of stocks did not exhaust the motives of participants, however. The desire to protect and enhance profits from sales of goods by achieving a higher degree of market control and by weakening competition was also important. One of the easiest ways to eliminate competition is to buy out competitors. Certainly a substantial number of mergers enabled surviving corporations to enjoy a leading and often dominant position in their respective markets. The degree in which control was concentrated rose markedly. In 1905 the census reported a total of about 216,000 industrial establishments in the United States. About 24,000 of these, or approximately 11%, controlled 81% of the capital, employed 72% of the wage earners, and accounted for 79% of the value of the product. Between 1870 and 1905 the output of the steel industry increased tenfold in volume, but the number of establishments declined from 1,808 to 606. The average capital investment in an iron and steel plant amounted to only \$150,000 during the 1870s. Thirty years later the average was \$1,500,000.

Investment bankers as well as industrialists wished to protect profit margins by narrowing competition. Excessive competition among the railroads had led to their financial intervention in that field. When they turned in the 1890s to industrial firms they saw the same threat of small returns and of bankruptcy from cut-throat competition. Unless purchasers of industrial securities were protected from this threat their own profits from securities sales would be placed in jeopardy. As in the case of railroads, therefore, an investment banking house insisted that one or more of its representatives have a seat on the board of directors, and that the house act as fiscal agent for the corporations whose securities it handled. In a position to veto costly and unwise plans, these representatives gave to investment bankers a potentially high degree of control over the operations of industrial firms. Usually the only positive aspect of that control, however, was a frequent selection of the firm's chief executive and perhaps other leading officers. What investment bankers wished to be sure of was that the "right" men were in, men who were willing and able to run the business in line with an understood over-all policy and with profit.

Investment banking control was nevertheless of high significance and during this brief era of "finance capitalism" it ramified to the outer edges of the American economy. By acting as fiscal agents for industrial firms investment bankers became their depositaries, using the sums deposited to invest in their securities business generally. To serve the capital needs of the largest corporations they acquired control of insurance companies and other main customers for securities, as well as sources of credit. By purchasing controlling shares of stock or forming interlocking directorates with insurance companies and commercial banks with funds to invest, investment bankers became the pivot wheel for a large area of economic activity. Morgan was said to have exerted a powerful influence upon banks and trust companies whose resources amounted to \$723,000,000. The colourful but exaggerated report in 1912 of the Pujo committee of the house of

approximately 1,200 were consummated. Unlike the first merger wave, in which combinations had attained very high percentages of the output of their industries—seldom less than 50%—merged firms during the 1920s generally secured much smaller percentages. The explanation is that mergers generally took place among firms which were smaller than the dominant firm in the industry. The effect was a gradual lessening of the dominant firm's share of an industry's production. Steel, petroleum, agricultural implements and automobiles were among industries in which the structure of the market changed from near-monopoly to oligopoly (few sellers). Some industries which had enjoyed a notable degree of competition, such as dairy products and packaged foods, also emerged with oligopolistic markets. By 1932 the 200 largest nonfinancial corporations controlled nearly 50% of total corporate wealth, and received nearly 50% of total corporate income. Since corporations produced in 1929 more than 90% of all manufactured goods, the leading 200 dominated the U.S. industry. Mining and transportation also made wide use of the corporate form, but it was rare in agriculture, service, finance and trade. Consequently, the 200 largest received only 10% of the total national income, a substantial proportion nevertheless.

**1. Antitrust Enforcement.**—After a period of virtual suspension of the Sherman act under the National Industrial Recovery Act (1933-35), a vigorous program of antitrust enforcement was begun in 1937 by Thurman W. Arnold, head of the antitrust division of the department of justice. More prosecutions were begun between 1937 and 1948 than in the entire history of the Sherman act before 1937. Actions were brought mainly against established oligopolies, but although the government won most of the major cases, the courts as a rule imposed only mild penalties. The issuance of drastic dissolution orders would have made for firms of uneconomic size, and the courts were reluctant to take this step. The aftermath of a circuit court ruling in the case of 1945 illustrates the modern problem of antitrust: how to ensure the largest number of sellers in industrial markets consistent with the economies of mass production. In this case Judge Learned Hand rejected both the rule of reason and the distinction between loose-knit and close-knit combinations. It did not matter that the recent history of Alcoa disclosed no evidence of predatory business practices. Evidence of intent to monopolize was to be sought not in predatory practices but in general business activity which culminated in monopoly power. Although Alcoa made over 90% of the virgin aluminum manufactured in the United States the court refused to order either dissolution or divestiture of assets.

**2. Conglomerate Mergers.**—After World War II a third merger wave occurred. In the 1951-55 period the total number of mergers was substantially higher than for any other five-year period in the preceding quarter century. Many of these mergers were of a type known as "conglomerate," the acquisition by one enterprise of another engaged in a noncompetitive field, as a means of diversifying its interests. The diversification movement has probably been the outstanding corporate development of the century. Beginning about 1904, it gathered momentum following World War I and became widespread after World War II. Its development, together with the very important administrative changes to which it has given rise, is of such significance that it is hardly too much to say that they are the main characteristics by which the contemporary corporation may be distinguished from its "modern" predecessor.

Because it turns out many products instead of only one, the large corporation has had to work out a more complex administrative structure to replace the simple one used by its predecessors. As Alfred D. Chandler, Jr. has shown, the functional departments proved unable to handle problems arising from the engineering, production and marketing of entirely different goods. In consequence, as the corporation moved into new lines of products, a multifunctional unit called a division was set up for each major product line or large geographic area. Each division has a central office that administers a number of departments, responsible for the administration of a major function, such

as manufacturing, sales, finance or research and development. Each of the departments in turn has a departmental head, officers that co-ordinate, appraise and makes plans for a number of field units. Field units are at the lowest administrative level of the corporation, each of them running a plant or works, a district sales office, a purchasing office, an accounting office or some other similar unit.

Over all of these administrative levels, at the top of the corporate pyramid, is the general office, where executives and staff specialists co-ordinate, appraise, plan goals and policies, and allocate resources (funds, equipment or personnel) to the various divisions. Each division tends to be quasi-autonomous and fairly self-contained. Because of this fact, and because it is the divisions that handle the various products the corporation turns out, the contemporary corporation is decentralized in its administrative structure. Nevertheless, the power of final decision-making rests with the executives in the general office. Their power derives from the fact that it is they who define the strategic, long-term goals of the enterprise and decide the purposes for which its resources are to be used. As Fritz Redlich and Alfred D. Chandler, Jr. have pointed out, these executives are the key men, the entrepreneurs of the enterprise. Those whose decisions must be made within the confines of the executives' over-all policies and allocations of resources are managers.

The men at the top who determine the goals of corporate enterprise are professional entrepreneurs, who have only a very small ownership interest in their enterprises. Ownership of voting stock is so widely scattered among tens of thousands of shareholders, however, that it is extremely difficult for a dissident minority to dislodge a management in power. The effort is not often made, partly for this reason and partly because the great majority of stockholders are indifferent to management decisions so long as dividends on their stock are paid regularly and without diminution. Forming a cohesive group, these top executives seek to perpetuate themselves indefinitely by moving into new and profitable product lines. Oligopolistic market power provides substantial insurance against loss from declining prices or uncontrolled production, and management's control of dividend policy provides ample funds for expansion into new areas, into which the corporation may move either via internal research and development or via the acquisition of other firms. While the latter process seems to have won favour in recent years it is improbable that the degree of concentration in industry has thereby increased. The number of mergers has increased but so too has the number of enterprises in a growing economy.

**10. Pros and Cons of Antitrust Laws.**—The facts help explain why some observers do not regard the "size" of the contemporary corporation as a major problem. They do not consider the antitrust laws to be of great importance, especially because congress from time to time has successfully exempted from their operation agricultural cooperatives, export trade associations, labour unions and other groups. The Robinson-Patman act does not place a greater emphasis upon protecting small-business competitors than upon preserving competition. Some point to the existence of a "new competition" in service, in new products and processes, and in advertising, and urge that it fosters consumer interests in ways which the old price competition failed to do. Some argue that the old competition among sellers on the same side of the market has given way to a "countervailing power" from the other side of the market, with mass buyers and large trading unions arising to share the grip of oligopolistic sellers. Others point to the existence of inter-industry competition, arguing, for example, that competition from television, sporting events and other forms of entertainment would make it impossible for a monopoly in the motion picture industry to exploit the public. Still others, finally, point to the emergence of a sense of social responsibility on the part of corporate managers, and demand that contemporary rule in terms of efforts to effect a just balance between the claims on corporate earnings of workers, investors, consumers, suppliers, the local community and the nation.

On the other side of the question are those who value the an-

trust laws. Many view them as a "big stick," the occasional exercise of which will deter excessive concentration. Few are sure where to draw the line between big and bigger, but most believe that one must be drawn somewhere, and that the government must draw it. For one thing, they fear the great economic power of the giant corporation. Excessive concentration inhibits efficient allocation of resources and impedes economic growth. The separation of ownership from control they acknowledge to be as old as the use of the corporate form in business, but such is the contemporary prestige of large size that they fear professional entrepreneurs may use their control of dividend policy to keep earnings in the business for the purpose of financing unwise expansion. Decisions to move a huge plant to another area for the sake of tax or other cost advantages may result in the deterioration of older communities. They fear, too, that the edge of entrepreneurship will be dulled in the soft routine of bureaucratic processes. Obviously, some of these apprehensions also have social and political overtones. Some men are concerned over the power of great corporations to mold the tastes and shape the values of Americans. Perhaps their most fundamental concern is the extent to which American democracy, which evolved in a society made up of comparatively small and competing enterprises, is threatened by bigness and by agreement. In some, no doubt, there is nostalgia for an older and simpler age, a nostalgia which is reminiscent of the Jacksonian mood when industries and cities first began to grow rapidly. Many now as many then find themselves pulled in two directions. On the one hand they applaud the high standards of living which big business has done much to bring about. On the other, they feel some or all of the anxieties mentioned. The ambivalence of the American people themselves in regard to antitrust legislation goes far to explain the ambivalence of their government. (S. By.)

## II. CORPORATION LAW

The major innovations in corporation statutes since the start of the 20th century have been: (1) the authorization of shares without par value; (2) the adoption of more detailed and specific provisions with regard to the funds legally available for distributions to shareholders either by way of dividends or of purchase by a corporation of its own shares; (3) the broadening of directors' powers, particularly in connection with the issue of shares; (4) the imposition of restrictions on shareholders' suits in a number of important jurisdictions; (5) the inclusion in the statutes of broader provisions for the amendment of certificates of incorporation by majority vote of the shareholders; (6) some further catering to the desires of promoters of combinations of corporations by permitting corporations to merge even if they have widely different powers or are organized under the laws of different states; and (7), largely since 1950, the validating of provisions inserted in articles of incorporation and bylaws for restricting share transfers and requiring unanimous, or more than the normal statutory percentage of, shareholder or director votes for a quorum or for action at meetings of close corporations or "incorporated partnerships."

More important in their aggregate effect than these changes in the statutes under which corporations are organized was the invasion of the field of corporation law by other statutes, both state and federal, which regulate a variety of matters including public offerings of corporate securities, solicitation of proxies in large corporations, accounting methods, security issues and consolidations of railroads and public utilities, and which establish a national statutory system for the reorganization of insolvent corporations. There were also important developments in that part of business-corporation law which is not of legislative origin but has been evolved by the courts. Such judge-made business-corporation law, which was in a rather embryonic state in 1850, had attained a considerable degree of maturity by 1900, but it was modified and amplified in many important respects during the succeeding 60 years.

A further legislative development of indirect bearing on the law of corporations has been the enactment of statutes permitting partners to sue and be sued and to hold title to property in the

partnership name, to make agreements for the disposal of partnership interests on the death of any partner so as to preserve the continuity of the business in the survivors, and even to elect under certain circumstances to be taxed as a corporation for federal income-tax purposes. These statutes have tended to reduce most differences, except the difference of limited liability of shareholders and unlimited liability of partners, between the two forms of association and to make such differences depend more upon the particular provisions of the articles or bylaws of the corporation or the partnership agreement of the partnership.

**1. Organization of Stock Corporations.**—Most business corporations in the United States are organized under a general corporation act of some state which provides that the interests of the members shall be represented by transferable shares of stock. Such statutes usually authorize a group of three or more persons to form such a corporation by signing and filing in one or more public offices a document, officially called by some such name as "certificate of incorporation" or "articles of incorporation," but commonly referred to as the corporation's charter. The Delaware act, typical of many of these statutes, specifies that the certificate of incorporation state the corporate name, the place in the state of Delaware at which the corporation is to have an agent on whom legal process may be served, the nature of business to be carried on, the number of shares which are authorized, the amount of capital (not less than \$1,000) with which the corporation will begin business, the names and residences of the incorporators, and the limit, if any, on the duration of the corporation (which is now almost invariably organized for a "perpetual" duration). The liability, if any, of shareholders for corporate debts may be set forth, but it is rarely, if ever, provided for. If there are to be several classes of shares, with different dividend or other rights, these rights must be stated in the certificate of incorporation unless that document authorizes the directors to determine them from time to time as the shares are issued. A large measure of freedom of contract is provided by authorizing the insertion of additional provisions relating to such matters as the powers of the directors and shareholders and the extent to which shareholders shall have pre-emptive rights to subscribe to new issues of shares. In some states, such pre-emptive rights exist at common law unless expressly limited or denied in the certificate.

It not infrequently happens that, through carelessness or otherwise, business is transacted in a corporate name without complete compliance with the statutory conditions precedent to incorporation. Although the statutes of several states contain some provisions relating to this situation, such statutes rarely indicate whether the shareholders of such "corporations" incur full individual liability for the debts of the enterprise. Generally speaking, the courts have relieved them from such liability where the failure to comply with the statute has been unintentional and not of a flagrant character.

It is implicit in the statutes that no one can effectively act for a corporation before it has been legally organized. But these same statutes make it possible for any person who can pay a small organization tax to form a corporation by getting two other persons besides himself to sign the incorporation papers. It often happens that such a person, knowing that he can at any time create a corporation and provide it with a board of directors who will do as he wishes, makes promises about what the corporation will do when it has been formed or obtains from other persons what purport to be subscriptions for the proposed corporation's shares. Confronted with situations of this sort, the courts have evolved a theory by which, if the corporation accepts the benefits of the promoter's agreement with knowledge of its terms, it will be held to have "adopted" that agreement as a corporate contract. Conflicting answers have been given in different states to the question whether a preincorporation subscription can be effectively revoked by the subscriber before the corporation has been formed and is in a position to accept it.

**2. Powers of the Corporation; Shareholders; Directors and Officers.**—The legal powers of a corporation are those given it, expressly or by implication, either by the corporation law or by

its charter, which, in order to be valid, must be drafted in conformity with the corporation law. In exercising these powers the business corporation functions, to use political terminology, like a representative government rather than a pure democracy. The shareholders elect a board of directors, on which the statutes of virtually all states confer the power to "manage" the business. Under the Delaware statute, typical of many, the only powers expressly given to the shareholders are powers to elect directors, to enact bylaws (although the certificate of incorporation may confer that power on the directors) and to approve or disapprove directors' resolutions proposing charter amendments, reduction of capital, merger, consolidation, sale or lease of all the corporate property, or dissolution. Additional powers may be conferred on the shareholders by the certificate of incorporation, and the shareholders have implied power to ratify certain voidable acts of the board. They usually also have implied power to appoint an auditor and power to remove a director if, but only if, he has been guilty of misconduct.

In corporations whose boards of directors are composed of a large number of persons it is usual to delegate broad powers to executive or other committees, and many statutes expressly authorize such delegation. On the other hand, although it is impractical to carry on business effectively without delegating broad powers to individual officers, the statutes are usually silent as to the extent to which this may be done. Most statutes merely provide that corporations shall have at least three officers, a president, treasurer and secretary, without stating the functions of such officers except so far as these may be implied by the titles of their offices.

Unfortunately, the word president is ambiguous. When it is used to describe an officer of a business corporation, the word might mean a mere presiding officer or might mean the chief executive, as it does in the case of the president of the United States. Although some courts do not agree, there has been a tendency in the 20th century to hold that a person who deals with the president of a business corporation is entitled, in the absence of contrary information, to assume that the president is the chief executive and has rather broad power to bind the corporation by contracts and other business transactions entered into on its behalf. Furthermore, there is no doubt that broad powers may in all states be conferred on the president or any other officer, either expressly, by bylaw or directors' resolution, or implied, by tacit acquiescence by the board in the officer's exercise of such powers. That authority may thus be created by acquiescence is well settled, although it seems somewhat difficult to reconcile that result with another well-established principle, that directors cannot usually act except by formal resolution at a board meeting.

Even with regard to directors' acts, however, there has been a recent trend in the decisions to validate informal action not taken at formally convoked meetings, especially where all directors know of the action, the shareholders have acquiesced in such informality by directors, and no minority interests are adversely affected. This trend is an indication of the gradual cleavage between two branches of the law which were at one time substantially identical—the law of public corporations, such as cities, and the law of incorporated business enterprises. Generally speaking, the acts of a city official are not binding on the city unless his authority has been conferred upon him with proper formality and unless, in exercising that authority, he observes all the formalities provided for by law. In the 18th and early 19th centuries most courts were no less insistent on the necessity of strict observance of the rules if acts done in the name of a business corporation were to be treated as legally binding. But U.S. businessmen are notoriously impatient of formalities, which they tend to regard as unnecessary "red tape," and the courts have become increasingly reluctant to permit business corporations to repudiate obligations incurred in their name because of informalities in the authorization or execution of the instrument in which the obligation is embodied.

Judicial tolerance for irregularities does not extend, to the same extent, to action which is *ultra vires* in the sense that it

is either inconsistent with some provision in the certificate of incorporation or is not reasonably related to the purpose of the corporation as stated therein. Even in this area, the doctrine of most of the older cases that an *ultra vires* contract cannot under any circumstances be treated as a corporate act has been rejected by the courts of many states, which will not allow a corporation to repudiate such a contract if the corporation has received substantial benefits as a result of its performance by the other contracting party or if there has been part performance of the contract by either party. This modification of the more rigorous doctrine fails to prevent a corporation from engaging in a business not authorized by its certificate of incorporation, making contracts for future delivery or purchase of goods in connection with that business and then repudiating those contracts if the price level changes, leaving the other contracting party, who was probably justifiably ignorant of the provisions of the certificate, entirely without remedy. Consequently, the statutes of many states have now been changed to abolish the defense of *ultra vires* altogether in actions between the corporation and outsiders.

**3. Voting Rights and Voting Control.**—Although the shareholders have little or nothing to do with the day-to-day management of the business, they are the ultimate source of authority. Most statutes require an annual meeting of shareholders to be held, at a time usually provided for by the bylaws, and special meetings may be held on such call and notice as the bylaws prescribe. The shareholders, or those of them who have voting shares, elect the directors, and the consent of the holders of at least a majority of shares is necessary in order to liquidate a solvent corporation, merge it with another enterprise or amend its certificate of incorporation. Although the statutes make it impossible to divest the entire body of shareholders of voting power with respect to these matters, most state statutes do permit the creation of classes of shares which can be largely—in some states entirely—stripped of all voting rights by the insertion in the certificate of incorporation of provisions to that effect. In this area, however, the freedom of contract permitted by state corporation laws is greatly curtailed for some important types of corporations by a series of federal statutes. Some of these statutes forbid investment corporations and corporations which are being reorganized pursuant to the federal Bankruptcy act to issue any nonvoting shares. Others give supervision over the issue of shares by certain types of corporations to federal commissions, which are unlikely to approve the issue of nonvoting shares.

In corporations which have only one class of shares, voting power is ordinarily proportional to share ownership, each shareholder being entitled to cast one vote for each share held, but statutes or corporate charters frequently provide methods by which minority groups may obtain some representation on the board of directors. The most usual method is that of cumulative voting, by which, if there are five directors to be elected, a holder of a voting share may, if he chooses, cumulate his votes by casting five votes for one director instead of one vote each for five.

Directors cannot vote unless they attend meetings in person, but shareholders can vote either in person or by proxy. Most proxies are in fact given to persons connected with the management, but the shareholder may give his proxy to any one he chooses, subject to the practical limitation that the proxy will be ineffective unless the proxy holder attends the meeting. In the first 15-year period after World War II, a number of highly publicized proxy contests were waged between management and insurgent groups of large, publicly held corporations, and in some contests, notably the contest for control of the New York Central Railroad company, the slate of management directors was defeated and the insurgent group took control of the company.

It has been a not uncommon practice for the management to solicit proxies from shareholders without giving the latter adequate information about facts which they may need to know in order to determine whether the resolutions for which it is proposed to vote the proxies are compatible with the shareholders' interests. Here again federal law has intervened, in this case by providing that anyone who solicits proxies relating to the shares

of any corporation whose shares are listed on a stock exchange, of any electric or gas utility holding company or its subsidiary, or of any investment company must conform to regulations made by the Securities and Exchange commission—regulations which provide for a full measure of disclosure.

Since the directors of most corporations are elected for a term of one year and shares of voting stock are ordinarily transferable to new owners without restriction, there is sometimes serious risk that the membership of the board of directors may be changed so frequently as to make continuity of policy impossible. In order to secure greater continuity of management, or for the less defensible purpose of enabling persons with little or no financial stake in the enterprise to obtain long-term control over it, all or a majority of the voting shares of a corporation are sometimes turned over to voting trustees, who issue voting trust certificates in exchange for them. The effect of a voting trust is to give the voting trustees the sole power to vote the shares of which they become the legal but not the beneficial owners, while the holders of the voting trust certificates continue to be entitled to any dividends declared on the shares of which they remain the equitable owners. Statutes frequently restrict the maximum length of such trusts, usually to a period of ten years.

A possible alternative to the voting trust is a voting contract, by which the original owners retain their shares but agree to vote them in a particular way. Such contracts are regarded as valid by most courts if they amount merely to agreements to combine rather than to agreements to sell one's vote for cash or some similar consideration and if they are limited to voting at shareholders' meetings rather than at directors' meetings.

There are means other than the voting contract or the voting trust whereby the holders of less than 51% of the voting shares may secure control of, or what is called a controlling interest in, a corporation. (1) A considerable minority of the voting stockholders, such as the insider management group, may be closely organized and in agreement to vote together on certain questions, or at an election. The remainder may be unorganized and their votes divided in several ways, some of them even voting inadvertently with the organized minority. (2) A minority of all the stock may constitute a majority of the stock actually voting, as it is very unusual to have more than 75% of the stock represented at a meeting. (3) A minority group may be regularly successful in securing from other shareholders proxies to vote an aggregate of more than 51% of the shares. (4) Sometimes stock votes by classes and a minority class may be given the privilege of choosing a majority of the board of directors. In such a case, the majority of the preferred stock might elect a majority of the directors and thus control. (5) Stock with a strict vetoing power exerts a strong negative control over various affairs. A certain class of stock may be classified as nonvoting for ordinary purposes, and yet the certificate of incorporation may provide that certain things may not be done without the consent of the majority of this class. In such a case, the holders of the majority of this stock can block action. (6) Where statutes do not prohibit it, certificates of incorporation sometimes provide that more than a majority of the total vote shall be required to perform certain acts, such as the election of directors. In such cases a minority once in power can remain so by blocking elections and other actions requiring the larger vote.

**4. Fiduciary Obligations of Directors and Officers.**—It is the duty of directors and officers to exercise their powers for what they believe to be the best interests of the corporation. This does not mean that a director or officer can never put himself in a position in which his economic interests are to any extent adverse to those of the corporation—contracts by which a director agrees to buy from or sell to his corporation are sometimes desirable or even necessary for the corporation's economic welfare. It does mean that transactions between a director and his corporation will be set aside if the corporation so desires, unless the director is found to have acted with scrupulous fairness. Most courts have held that, unless the certificate of incorporation provides otherwise, a director's contract with his corporation must have the approval of a majority of the board at a

meeting at which the interested director is not counted either as part of a quorum or as part of a voting majority. There is a tendency to relax this latter rule—but not the requirement of fairness—in the case of a contract which is not between a director and his corporation but between two corporations having interlocking directors.

It is impossible to give a precise definition of what the courts mean by fairness in this connection. It normally includes a duty of full disclosure, not only of the director's adverse interests but of facts known to him which affect the desirability of the proposed agreement. Where, as is not infrequently the case, two contracting corporations are represented in the transaction by identical or nearly identical boards of directors, disclosure is meaningless and fairness must be determined by other criteria. Some courts have said that in such a case the question is whether the proposition submitted would have commended itself to an independent board, a test which is adequate in theory but difficult to apply if the subject matter of the contract is something which has no determinable market value.

One of the most difficult types of interested-director situations to deal with satisfactorily by judicial decision is that in which directors who are also officers of the corporation fix the compensation of the officers. Many corporations adopt the policy of electing boards composed wholly or chiefly of persons who hold executive positions. In such a situation the majority of the board have direct personal interests in the executive salary scale. Either the function of determining such salaries must be transferred from the directors as managers to the shareholders' meeting—a body not ordinarily well qualified to decide matters of that kind—or the courts must make an exception to the rule that directors' action is not binding unless there is a disinterested majority and must sustain the salaries voted by the board if it finds them to be fair. A number of states have enacted statutes permitting interested directors to fix their own compensation as officers if the amount of the compensation is fair and reasonable.

Another area of uncertainty in the law involves the permissible degree of conflict between the corporation and its officer, whether or not a director, who has an interest in a seller to or purchaser from the corporation, or in some other way stands to make a direct or indirect personal gain from a corporate transaction. The trend of the law to validate such transactions if deemed "fair" would indicate that a profit by the officer would not be struck down if the corporation received the same profit or advantage and paid the same charges and costs, that it would have in the absence of such a conflict. The question remains, however, whether disclosure of such a conflict to the board of directors should not be required, and if the officer is a director, and especially if an important or dominating director, a disclosure by the board to the shareholders; and if so, whether a vote ratifying the propriety of such a conflict under the circumstances disclosed should not also be required.

The directors' fiduciary duty of loyalty to the interests of their corporation is not limited to cases in which directors are dealing with the corporation or are acting for two corporations that are dealing with each other. It is applicable to many other situations including that in which the director intercepts a corporate "opportunity" by acquiring property for himself instead of for the corporation. The law does not forbid a director ever to purchase for himself anything which the corporation might wish to have bought. It does compel him to turn over to the corporation at cost property which, but for his interference, the corporation would probably have been able to obtain for itself and also property which he acquired while director, knowing that it was vitally needed by the company and not essential to his own outside interests. Some of the older cases tended to restrict the term corporate opportunity to these two situations, but the later trend of the cases has been to take a broader view of the director's obligation, treating as significant though not necessarily as conclusive such factors as whether the corporation was already in the market for the property, whether the information that the property was available came to the director by reason of his official position, whether its acquisition would put him in a position adverse to the

corporation, whether the corporation was financially able to buy, and whether the corporation would have had a normal business interest in purchasing or taking advantage of the property or opportunity in question.

In addition to their duty not to allow the decisions which they make as managers to be warped by self-interest, directors owe the further duty of reasonable care and prudence. The courts differ a good deal in the language which they use in describing the degree of care which directors are legally bound to exercise, but the language used to describe the duty is less significant than the results actually reached.

Imprudent management by directors is of various kinds. It may result from failure to attend meetings, from failure to keep well enough informed about corporate affairs to act intelligently at meetings, from failure to supervise or to provide for adequate supervision of subordinates, or from reckless or incompetent business judgment. Directors who are not also executive officers are rarely highly paid. Individual directors are frequently elected members of the board for reasons other than their business skill. Courts tend to treat them more leniently than full-time salaried officers with respect to their duty of care. Nevertheless, failure to attend meetings with some degree of regularity and failure to make any substantial effort to keep informed about corporate matters will be condemned as negligence, although a director whose negligence is judicially criticized will sometimes escape liability because of the difficulty of proving that his negligence was a substantial cause of the loss for which it is sought to hold him liable. Failure by the directors to provide for the supervision of subordinates has resulted in legal liability in a number of cases relating to banks whose assets have been looted by dishonest employees, and, much less frequently, in cases relating to other kinds of business. Legal liability for errors of business judgment has generally been denied, although here again there is a tendency to treat bank directors somewhat differently and to insist that the directors of such institutions, which purport to be places of safekeeping for depositors' funds, will be liable if they embark the bank upon disastrous ventures of a highly speculative character. The legislatures have, with few exceptions, left questions relating to directors' duties of loyalty and care to the courts.

On the other hand, there have been very important statutory additions to the law governing the conduct of a director who is not acting for the corporation but is purchasing some of its shares from a shareholder. Most of the earlier judicial decisions in this field permitted a director to buy without disclosing any inside information which he might have. The reason given for this lenient rule was that, although the director was a fiduciary for the corporation, he was not a fiduciary for its individual members. The practical effect of the rule was to enable a director, in dealing with individual shareholders, to take advantage of information which he had obtained by reason of the position to which he had been elected by the shareholders, acting as a body. Many courts have repudiated this view and have either required full disclosure in all cases or insisted on it in cases where the situation is such as to make purchases without such disclosure peculiarly inequitable.

The broadest of the three rules—that requiring full disclosure under all circumstances—is required by sec. 10 of the Securities Exchange act of 1934 and the rules which the Securities and Exchange commission has promulgated pursuant to that section for cases in which the director brings himself within the regulatory powers of congress by using the mails or some other instrumentality of interstate commerce. Although the language of both statute and rule is rather vague, it imposes a requirement of full disclosure on directors, officers and other "insiders" who purchase shares or any other kind of corporate securities, regardless of whether the purchase is made on their own behalf or on behalf of the corporation. Other federal statutes provide that, if the securities are shares of stock listed on a stock exchange or shares of a corporation to which either the Public Utility Holding Company act of 1935 or the Investment Company act of 1940 is applicable, a director, officer or large shareholder who purchases and resells (or who sells and repurchases) the shares within a six-month

period is liable to the corporation for any profits derived from the transaction. This latter provision, which gives no remedy to the seller of the shares, is designed to discourage the practice of short-term market trading by corporate officials.

**5. Legal Obligations of Promoters and Controlling Shareholders.**—It is possible to promote a corporation and to dominate its original board of directors without becoming, in any formal sense, its official representative. A promoter who organizes a corporation in this manner is in a position to make highly inequitable contracts with the corporation and to obtain large profits from it which will seriously lessen the value of the securities it issues to other people. The courts have attempted to cure this evil by obliging the promoter either to permit rescission of the transaction or to surrender his secret profit. Promoters have frequently found means of evading these obligations successfully, and judicial remedies for the recovery of promoters' secret profits have in practice proved much less effective than the requirement of full disclosure at the outset made by the Federal Securities act of 1933, a statute applicable to most situations in which corporate securities are offered to the public.

A majority shareholder, or a group of shareholders who act in concert and together constitute a majority, can, like a promoter, make use of the power of control over the corporation to make contracts with it which deplete its assets and cause loss to its other shareholders. A compact minority group will often be able to achieve similar results if the majority have no effective means of uniting. Since shareholders have not, like directors, undertaken to act for the corporation's benefit, they are not subject to all the legal disabilities which are applicable to directors. For example, like voters in a political election, they are not disqualified from voting because of any adverse economic interest which they may have. Nevertheless, they will not be permitted to use their voting power to achieve results which are clearly designed to harm the corporation, and it is immaterial whether they attempt to achieve such results through control over the directors or by exercising their power as shareholders to vote on such questions as the dissolution of the corporation. Furthermore, some recent cases have thrown doubt on whether a shareholder bloc constituting effective control of the corporation may sell the controlling shares at a price paid in part by the purchaser to secure a corporate advantage arising out of control, unless the seller accounts to other shareholders for that part of the selling price which constituted a premium paid by the buyer to secure the corporate advantage or other concomitant of control.

**6. Shareholders' Suits.**—Officers, directors and controlling shareholders would, as a practical matter, often be able to violate their duties to the corporation with impunity if it were not for the invention by courts of equity of what is called the shareholders' derivative suit. The power to bring suit on a corporate cause of action is ordinarily vested in the directors, who will not exercise that power if they are themselves the wrongdoers. If the majority shareholders are not themselves participants in the wrong, they can, in theory and sometimes in practice, elect a new board of directors composed of persons who can be relied upon to bring suit if the corporation's interests require it. But if the shares of those who have not participated in the wrongful action are owned in small lots by a large number of people, replacement of the wrongdoing directors will be difficult to achieve. Unlike the situation which usually prevails in politics, there is rarely in the business corporation any organized party of the "outs" competing at each election with the party of the "ins," and to create one for a particular purpose is often impracticable.

To meet this situation, the courts developed the shareholders' derivative suit, by means of which one or more shareholders are permitted to sue on a corporate cause of action for the corporation's benefit, if the board of directors unreasonably refuses to sue, or if, because the directors are the alleged wrongdoers, they are not proper persons to have charge of the litigation as representatives of the company. Such suits have often served a very salutary purpose. They have also led to serious abuses. An ill-founded shareholders' suit against directors may cause the corporation serious loss, because the litigation may interfere with

the conduct of the business and because the corporation will in many states be obliged to reimburse for their legal expenses directors who have successfully defended themselves. Moreover, there is danger that the shareholder's real purpose may not be victory for the corporation but his own individual gain. If the shareholder wins the suit, it is the corporate treasury, not the shareholder's pocketbook, which is directly enriched, and the shareholder will not even participate substantially in the fruits of victory indirectly, through enhancement in the value of his shares, unless those fruits are very large or the shareholder owns a substantial percentage of the corporation's shares. On the other hand, if the wrongdoers can, by settling with the litigating shareholder, avoid any serious risk of being sued later on by anyone else, it may be worth their while to make a direct payment to the shareholder of a much larger amount in settlement of the suit than the amount by which the value of his shares would be enhanced if he won it for the corporation whose champion he purports to be.

Two very different kinds of remedies for these evils have been attempted. One kind, of which the federal courts have been the chief exponents, seeks to make it difficult for the shareholder to make the derivative suit a source of personal gain by providing that, once suit has been brought, it cannot be dismissed or compromised without court approval, on such notice to all the other shareholders as the court may direct, and also by treating anything which the shareholder is paid for abandoning the suit as in law the property of the corporation.

This line of attack on so-called "strike" suits has not been wholly successful, and several states have followed the lead of New York in adopting statutes which impose restrictions of a very different type. Many statutes do away with the possibility of purchasing shares for the purpose of bringing suit by limiting the right to sue to those who owned shares at the time of the acts complained of. In addition, on the theory that small shareholders, who have little to gain from a corporate victory, are particularly likely to bring suit for purposes other than achieving such victory, shareholders whose holdings are relatively small are required in a few states to give security for and ultimately to pay the reasonable legal expenses of the corporation and any of its directors, officers or employees who are defendants in the suit and succeed in establishing their freedom from legal liability. It is legally possible for a group composed wholly of small shareholders to avoid the effect of this provision if a sufficient number of them join together as coplaintiffs, but such united action in large corporations has proved practically difficult, with the result that the number of derivative actions brought in states having such statutes has been very sharply reduced. A California security-for-costs statute avoids the necessity for such united action by making the requirement for security depend not on the size of the shareholder's holdings but on whether the court finds that there is no reasonable probability that the suit will benefit the corporation.

A shareholder who seeks to bring suit on behalf of the corporation would be greatly handicapped if he were unable to obtain reliable information about corporate affairs. The courts have come to his assistance by holding that he has the right to inspect the books and papers of the corporation for any purpose reasonably related to his interests as a shareholder, including the purpose of determining whether his suspicions that there is an adequate basis for a shareholder's suit are well-founded. This right usually includes the right to inspect and copy the list of shareholders' names and addresses preparatory to circularizing them in a proxy contest.

Generally speaking, a shareholder has no legal right to obtain information except in this manner. It may seem surprising that there are only a few states in which it is the legal duty of management to send the shareholders an annual financial report, but it should be borne in mind that corporation laws are intended not merely for corporations whose shares are widely distributed but for those which have only a handful of shareholders.

Most large corporations are required by federal statutes to make periodic public reports of their assets and earnings and, in certain cases in which proxies are being solicited by the management, to furnish financial reports to their shareholders.

**7. Types of Corporate Securities.**—The principal types of corporate securities are common shares, preferred shares, bonds and debentures. Preferred shares and bonds may be convertible into other types of securities, and the corporation may also have warrants outstanding. Warrants are transferable options, of unlimited or limited duration, to purchase shares of the corporation at a specified price, and they are usually issued initially attached to bonds or preferred shares as an added inducement to buy. All corporations have common shares; they may or may not have securities of one or more of the other types. As a general rule, all types of securities are transferable, bonds and debentures by mere delivery, preferred and common shares by delivery of the share certificate accompanied by a transfer power, which is generally embodied in a separate instrument. Preferred shares have priority over common shares with respect to dividends at a limited rate and, under some types of preferred-share contracts, participate with the common shares in such additional dividends as may be declared. They are usually preferred and limited also in their rights in corporate assets in case of dissolution.

Bonds and debentures, which are long-term debts, are rarely dealt with to any great extent in corporation statutes, the rights of the holders of such securities being determined for the most part by the law of contracts and, in the case of bonds secured by an indenture of trust, by the law of security and the law of trusteeship. The word debenture, which is not a technical legal term, is generally used in financial circles to mean an unsecured bond. Bonds and debentures that are publicly offered for sale must, with certain exceptions, conform to the requirements of the federal Trust Indenture act of 1939, which contains some provisions of rather limited scope for the protection of the holders of these types of securities. (See also STOCK; INVESTMENT PAPERS; BOND [IN FINANCE].)

**8. New Issues of Shares.**—In the absence of any provision to the contrary in the certificate of incorporation, each shareholder has under the law of most states the right to subscribe for his proportionate part of any new issue of shares of his corporation in order that he may preserve his proportionate interest in the assets and earnings of the corporation and his proportionate voting power.

This pre-emptive right is subject to various exceptions. It does not, for example, apply to shares which are issued for property or to so-called "treasury" shares (shares previously issued and subsequently reacquired by the corporation). In cases in which no pre-emptive right exists, the directors ordinarily have power to select the persons to whom shares shall be issued, but that power is subject to their duty as fiduciaries not to issue shares at less than their fair value (unless they are issued to all shareholders in proportion to their previous holdings) and not to issue them for the purpose of giving some particular group voting control over the corporation.

The public sale of new issues of securities which are fraudulent or are offered without sufficient disclosure of essential facts about the enterprise has engaged the attention of state legislatures. A large majority of the states enacted so-called blue-sky laws, which require that the persons who sell the securities and, subject to certain exceptions, the securities themselves, be licensed by some state administrative agency.

The statutes of a few states, including New York, instead of requiring licences for the public sale of securities, authorize the attorney general to investigate fraudulent practices in connection with such sales and to institute injunction proceedings.

The Federal Securities act of 1933 differs radically from most of the state laws in that its sole purpose is to compel full disclosure. It provides that, with limited exceptions, no corporate security can legally be offered to the public by mail or by means of any instrumentality of interstate commerce unless the issuer has filed with the Securities and Exchange commission and made public a registration statement containing full information about the security and the issuing corporation. The commission is given power to institute proceedings to prevent sale of the securities if no such statement has been filed or if it finds that the statement is in any material respect false, misleading or incomplete. Most of

the information included in the registration statement must be included also in a prospectus, which must be given to each original purchaser at or before the time of delivery of the security.

In the case of railroads and other public utilities a different kind of administrative regulation of security issues, designed as much to safeguard the general public against unsound financing of essential utilities as to protect buyers of securities, is provided for by various federal and state statutes. (See SECURITIES REGULATION.)

**9. Shareholders' Individual Liability.**—Shareholders whose shares are paid for in full are, generally speaking, immune from any other substantial liability for corporate debts, although some corporation laws make them personally liable for wage claims in case of corporate insolvency. The special liabilities imposed on shareholders of national and state banks had been abolished almost everywhere by mid-20th century.

If a corporation's shares are what is known as par-value shares, full payment for shares means, as between the shareholder and corporate creditors, payment of the par value in money, property or services. The statutes of many states provide or are construed as providing that the judgment of the directors as to the value of any consideration other than money is conclusive in the absence of fraud. When there are no par-value shares issued for cash, the shareholder assumes no liability, either to the corporation or its creditors, except to pay the agreed consideration. When such shares are issued for property, it is necessary to put a dollar valuation of the property on the corporation's books. The law at mid-20th century was still unsettled as to circumstances under which a shareholder would be treated as a participant in such valuation and held liable to creditors if the valuation was not based on an honest business judgment. But since most shareholders know the dollar valuation (or "stated value") fixed by the corporation for its no par shares when it issues them, a shareholder or seller who conveyed property known by him to have been taken and put on the books at a valuation higher than the stated value of the no par shares issued to him for the property may well be liable for the difference.

A shareholder who is in control of a corporation is sometimes subject to more drastic liabilities. Immunity from individual liability is not forfeited by acquiring a majority or even all of a corporation's shares, but a sole shareholder, and, less frequently, a controlling shareholder, has been held liable for corporate debts or damages where he or it (for liability has most often been imposed where the controlling shareholder is a "parent" corporation) fails to keep the corporation's business transactions clearly separate from his own and where he gives those with whom he deals the impression that the corporation's debts are his own obligations. Furthermore, a person who does business mainly at the risk of his creditors by forming a corporation with very little capital and then expanding the scope of its operations by furnishing additional funds, ostensibly in the form of loans, is likely to have his claim subordinated by the courts to those of the other creditors if the corporation becomes insolvent. Although a corporation is treated for most purposes as a legal person which is separate and distinct from its members, the courts will not, generally speaking, permit a person or group of persons to evade a statute or a contract by causing their corporation to do what the statute or contract forbids them to do in their individual capacities.

**10. Dividends and Other Distributions.**—Distributions of corporate assets by corporations are mostly in the form of dividends. Most corporation statutes restrict the funds available for dividends to surplus or to some types of surplus. In the case of par-value shares, surplus ordinarily means any excess of net assets over the aggregate par value of all outstanding shares. In the case of no par-value shares, it ordinarily means any excess of such assets over that part of the consideration paid for the shares which has been designated as capital by the board of directors.

Some statutes forbid the payment of dividends out of surplus derived from an increase in the value of such fixed assets as buildings and machinery, and some greatly restrict the use for dividend purposes of surplus contributed by shareholders as part

of the purchase price of their shares and which has been designated on the corporate books not as capital but as some form of unearned surplus, such as "paid-in surplus."

The statutes of a few states expressly authorize corporations to pay dividends out of current earnings without applying those earnings to eliminate a deficit from operations of prior periods, and those of several other states are so worded as to make a similar interpretation of them not unlikely. Such current earnings can be made available for dividends in other states in one way only—by having the shareholders vote to reduce the amount of legal capital to an extent sufficient to eliminate any deficit from prior operations and thus turn the current earnings into surplus.

Purchases by corporations of their own shares constitute another method by which corporations may distribute part of their assets to a shareholder or shareholders. If payment for the shares is made out of capital and the shares are not resold, the effect on the corporation's financial status is the same as though it had paid dividends out of capital. In most states the law applicable to such purchases is substantially identical with the law of dividends, but a few states still have very lax rules relating to such purchases.

The practical application of legal rules relating to the funds legally available for dividends or for purchases of shares often raises difficult questions of the proper accounting methods for determining such matters as surplus, earned surplus or current earnings. In most states, directors are immune from liability for declaring improper dividends if they have acted with due care, and shareholders who have received dividends or other distributions in good faith are not required to refund them if the corporation, despite the impairment of its capital, was solvent at the time of distribution.

**11. Amendment of Corporate Charters.**—A corporate charter is, for purposes of federal constitutional law, both a contract between the corporation and the state and a contract between the corporation and its shareholders.

Most states have, by a provision in the state constitution or by legislation, reserved power to amend corporate charters. Although there is considerable conflict in the decisions as to the scope of such reserved power, many courts have held statutes which give wide powers of amendment to majority shareholders constitutional, even as applied to corporations created prior to their enactment.

The amending powers granted majority shareholders in most states include not only power to change the nature of the business but power to change the dividend, voting, or other special rights of a particular class of shares. Changes of the latter sort usually require the affirmative vote of at least a majority of the class of shares affected. Where a majority has voted for the change, some courts treat the question as one of business judgment and refuse to interfere, at the request of the minority, unless the unfairness of the amendment is so gross as to justify the inference of fraud. This view allows pressures to be brought to bear on preferred shareholders to induce them to consent to an inequitable modification of their rights.

**12. Merger and Consolidation.**—Another method by which shareholders' rights may be radically changed is by the merger or consolidation (the distinction between the two, in many contexts, is of little importance) of two or more corporations. If each corporation has only one class of shares, the effect of the merger is to modify the individual shareholders' rights only to the extent of making him an investor in a substantially different enterprise. But if one or more of the corporations has several classes of shares, the merger agreement may validly provide for such changes in class rights as the substitution of common shares of the combined enterprise for preferred shares of one or more of its constituent companies. Some courts have permitted a corporation, by creating a subsidiary company and then merging with it, to make changes in preferred shareholders' rights which could not be made by direct amendment of its certificate of incorporation. Under most merger statutes, however, dissenting shareholders are given the right to withdraw from the enterprise and to be paid the appraisal value of their shares in cash.

**13. Dissolution, Bankruptcy and Reorganization.**—A solvent corporation may be dissolved and its business wound up as a result of the voluntary action of its shareholders. The winding up of an insolvent corporation may be either voluntary or involuntary. The usual, although not the only possible, procedure by which the affairs of insolvent corporations, other than banks, insurance companies and railroads, are wound up is by proceedings in a federal court of bankruptcy.

Insolvency does not, however, necessarily result in liquidation. A corporation may be insolvent, either in the sense of having insufficient current assets to pay its debts as they mature or in the so-called "bankruptcy" sense of having liabilities which exceed the fair value of the assets, both current and fixed.

Despite insolvency of either type, it may have a substantial going-concern value, and the best or even the only way in which that going-concern value can be realized by its creditors may be through a reorganization, by which the assets are not sold to outsiders but the old creditors become the principal or the sole owners of the reorganized company.

Congress amended the Bankruptcy act in 1938 to provide for the reorganization of most types of corporations by means of proceedings in a federal court. The plan of reorganization, which usually involves the exchange by the creditors of all or part of their debt claims for shares of stock, must, generally speaking, be assented to by the holders of two-thirds of each class of debts.

Unless the corporation is found to be insolvent in the bankruptcy sense of that word or its junior shares are found to be worthless, the plan must also be assented to by the holders of a majority of each class of shares. In addition, it must be found by the court to be fair and equitable and financially feasible.

A study of reorganization under an earlier form of procedure, made under the auspices of the Securities and Exchange commission, produced impressive evidence that creditors, because of ignorance, inability to organize effectively for common action, or eagerness to have the reorganization completed without long delay, had frequently agreed to reorganization plans which were unduly favourable to junior interests. The U.S. supreme court endeavoured to prevent plans of that type from being approved by the lower federal courts by admonishing them that, regardless of how large a percentage of any class may have assented to the plan, the judge must not approve it as fair and equitable if it fails to eliminate the holders of worthless junior securities entirely, or if, where such junior interests are found to have some value, it fails to give senior security holders a substantial equivalent for any rights which they give up.

In the reorganization of most types of corporations under federal law, the Securities and Exchange commission was given a purely advisory role. That agency has much broader powers if the corporation is a gas or electric holding company or a subsidiary of such a company and is being reorganized either because of insolvency or because its security structure is not in conformity with the requirements of the Public Utility Holding Company act of 1935.

The Interstate Commerce commission was given somewhat similar powers in connection with the reorganization of railroads, both when the railroad is being reorganized under the Bankruptcy act and when the directors of a solvent railroad, acting in accordance with the provisions of a 1948 amendment of the Interstate Commerce act, seek to induce the holders of 75% of each class of its securities to consent to a modification of what the directors consider an unsatisfactory security structure. (See also BANKRUPTCY.)

**14. Other Types of Business and Private Corporations.**—The most important types of nonstock business corporations in the United States are mutual insurance companies and savings banks. The members of mutual insurance companies are the policyholders. Although most agricultural and other co-operative associations are stock corporations, they are usually organized under statutes which narrowly limit the amount of stock which any member can hold and provide that, after a limited dividend has been paid, any additional earnings shall be divided among the members in proportion, not to their stock ownership, but to the amount which

they have bought from the association, or have sold through it, if it is a co-operative marketing association.

The statutes of most states contain separate provisions for the organization of religious, charitable, educational, social and other nonbusiness types of private corporations, which are usually designated collectively as corporations not-for-profit. These vary in type from small clubs or societies to large educational institutions. Both the statutory and the judge-made law applicable to such corporations is much less complicated than that applicable to incorporated business enterprises. Judges are very reluctant to take jurisdiction over controversies relating to their internal affairs where, as is often the case, such controversies are not primarily disputes about property but about whether the views or actions of some member are compatible with the tenets, objectives or traditions of the society.

**CORPORATION TAX.** Almost every industrially developed country recognizes, for business and taxation purposes, entities resembling the U.S. and British corporation, but few universally valid generalizations can be made about corporate taxation because of the wide variety of hybrid entities and the diverse approaches to taxation. Since World War II, taxes on corporations have provided an increasingly substantial part of the national revenues in most countries.

In the United States, in the second half of the 20th century, the corporation income tax was second only to the individual income tax as a source of federal revenue; and in most of the states as well, taxes on corporations had long made important contributions to the support of government activities. In Great Britain local taxation is of minor importance because of greater centralization of financial responsibilities in the national government. But the proportionate contribution of corporation taxes to total government revenues is roughly the same as in the United States. In both countries corporations were subject to heavy excess-profits taxes during war periods (see EXCESS-PROFITS TAX).

**History.**—In the United States the practice of taxing corporations as such began during the middle of the 19th century when a number of states found the general property tax to be an inadequate instrument for the taxation of corporate wealth. Pennsylvania introduced a capital-stock franchise tax in 1840, and Massachusetts devised the "corporate excess" tax in 1864. Although only 12 other states had followed Pennsylvania's lead by

1900, nearly three-quarters of the states had capital-stock franchise taxes by 1960. Taxes on the "corporate excess" (i.e., the excess of the market or fair value of the capital stock above the value of the property locally assessed or located outside the state) were levied by 16 states in 1912, but by only 2 in 1960. Other taxes paid by corporations are many and varied, though not limited to corporate taxpayers. These include taxes based upon property as well as many forms of excise taxes, principally customs duties on imports, taxes on transactions involving transportation, communication and other services, and excises on the privilege of manufacture, storage, and the sale or purchase of commodities.

Except for a brief period during the Civil War, federal income taxation of corporations began in the United States with the imposition of a 1% tax in 1909. This levy, which was merged with the new individual income tax in 1913, was for several years little more than a withholding tax on corporation stockholders. Shortly after World War I, however, the corporation income tax became more and more widely regarded as a tax on the corporate entity; and by 1936, when dividends for the first time became fully taxable in the hands of the individuals receiving them, the corporation tax had become truly a levy upon earnings of the corporation as such. Meanwhile, the corporation rate had been rising gradually from 10% in 1920 to the peak 52% which prevailed after 1951. From 1911, when Wisconsin introduced the first successful corporation income tax, more and more states made this tax their principal instrument of corporation taxation. By the 1960s corporation income taxes had been enacted by over three-fourths of the states and some cities, and accounted for substantial tax revenues.

Besides the wartime excess-profits taxes, the U.S. government experimented with several other types of corporation levies. During 1936-37 it imposed a tax on undistributed corporate profits at rates ranging from 7% to 27%. Although this tax was proposed as a substitute for the corporation income tax, it was enacted as a supplementary levy. Opposition to it was great, and it was repealed after only a two-year trial. From 1933 to 1945 corporations were taxed on the "declared value" of their capital stock. At the same time, a complementary excess-profits tax on earnings exceeding stated rates of return on the "declared value" had the effect of discouraging underdeclarations. Thus, the burden of the combined tax depended on the stability of the income and the accuracy of the forecast. Because of this unsatisfactory dependence on an estimation of earnings and in view of the increase in the regular corporation tax, these taxes were repealed in 1945.

In Great Britain, corporations and individuals alike are subject to income tax at the so-called standard rate. The corporation's payment of tax on its income at the standard rate satisfies all liability for that tax on the income. When the income is distributed as a dividend, tax at the standard rate is not imposed on the shareholder in respect of the dividend. Thus a corporation's income, whether distributed or not, bears but one tax at the standard rate. However, the shareholder is treated as though he has received, besides the dividend, the amount of that tax attributable to the dividend, and the combined amount has then to be included in his income for the purpose of calculating the graduated surtax imposed on individuals whose incomes are above the level at which surtax begins to be chargeable and for the purpose of computing total income by which various personal allowances are measured.

After 1937, Great Britain levied an additional tax on the income of corporations. Originally called the national defense contribution, this tax was levied at the flat rate of 5% of income. During World War II, an excess-profits tax was imposed in lieu of the national defense contribution wherever the excess-profits tax was the greater amount. Upon repeal of the excess-profits tax in 1946, the national defense contribution was renamed the profits tax and shortly thereafter its structure was changed so as to provide a deterrent against dividend distributions.

**Special Problems and Policies.**—In any system of corporate income taxation, there is the problem of interrelating the corporation's tax with the tax on the individual stockholders who own the corporation. There has been much concern over the so-called "double taxation" resulting when stockholders are taxed on divi-

dends received from corporate earnings despite the fact that the corporation may previously have paid taxes on the earnings. Great Britain, as stated above, has completely eliminated the double taxation effect as regards the standard rate. Australia, on the other hand, has imposed a highly progressive rate of tax on income received by corporations without any such mitigation, while Canadian policy has been to make some tax concession to dividends representing income upon which the corporation has paid a tax. Beginning in 1954 the U.S. congress made a limited concession to the argument for reducing the combined corporate and individual income tax levy on dividend income by adopting a \$50 dividend exclusion for individuals plus a credit against the individual income tax of 4% of dividends received. But in the case of intercorporate dividends, received by a corporation from another corporation, a very substantial exemption from income tax has long been the U.S. policy, resulting in a maximum rate of 7.8% in 1961.

In the United States and some other countries, one of the main problems regarding rates stems from the fact that the corporation tax is at a flat rate of approximately one-half the net income, whereas the individual income tax is at a steeply graduated rate up to 91%. Thus, for high-bracket taxpayers the corporate device has been used as a shield against the high-bracket income tax rates by allowing most of the corporate net earnings above taxes to remain undistributed year after year. Sometimes the individual stockholder will receive the accumulated earnings later by a sale of the stock, or through other devices, resulting in a tax at the lower capital gains rates instead of the much higher rates applicable to ordinary income (see CAPITAL GAINS, TAXATION OF). If the individual does not sell or liquidate the corporation until his death, the corporate earnings may even be passed on to his heirs without ever being subjected to the income tax rates for individual taxpayers. Two main statutory devices are used to curb this use of the corporation by high-bracket taxpayers: (1) an additional tax, known as the "accumulated earnings tax," upon the undistributed income of corporations used for the purpose of accumulating earnings to avoid the income taxes upon individual shareholders; and (2) a "personal holding company tax," which, in general, is imposed upon family corporations or other closely held corporations, 80% of whose income is from certain sources such as investment or personal services.

In order to permit small businesses greater choice of the corporate or noncorporate (partnership or individual proprietorship) form without overemphasis upon tax consequences, congress has permitted certain closely held corporations to elect, under limited conditions, the same tax treatment as if the stockholders were doing business as individual partners. A limited provision permitting certain unincorporated businesses to elect to be taxed as corporations had already been enacted in 1954.

The corporate income tax has international ramifications in its application to foreign corporations doing business within a particular country and also with respect to the treatment of income earned abroad by domestic corporations or their subsidiaries. Not least among policy considerations are the encouragement of foreign investment and the reduction of the impact of double taxation stemming from the power of two or more countries to tax. Quite generally, foreign corporations doing business within a country are exempted from local taxation, or are taxed only upon income earned in the country. International treaties and conventions are widespread between the United States and Great Britain and numerous foreign countries. Several mechanisms found in the income tax statutes of the United States reduce substantially the income earned abroad by domestic corporations. These include: (1) a tax credit for foreign income taxes paid by domestic corporations; (2) a tax credit for taxes paid by foreign subsidiaries; and (3) a lower income tax rate accorded "western hemisphere trade corporations."

Other important matters of policy relate to the types of charitable, educational and other corporations which are to be exempted from the corporate tax; and to the detailed treatment of the tax consequences, both to the corporation and to its stockholders, of such events as the transfer of property to the corporation upon

its formation and to the stockholders upon liquidation or partial liquidation of the corporation, as well as various exchanges of stock when the corporation is changed in form or reorganized. Important objectives are equality of treatment of taxpayers and prevention of tax avoidance. The technical aspects in devising corporate tax patterns are complicated, and many countries have been guided by United States and British experience. *See also* INCOME TAX; TAXATION.

**CORPSE**, a dead human body. In every age, the public interest has commanded a disposition of human remains in a manner consonant with existing mores. The dictates of modern western civilization require that a body must have burial, both for the sake of public health and in accord with the sentiment that the dead should be disposed of decently. However, cremation or burial at sea, where necessary, are permissible, as is delivery of bodies for dissection and study in accordance with the provisions of local anatomical acts.

In England, from the time of the Norman Conquest until the 19th century, the right of possession and disposition of a dead body was vested in the church and was solely the subject of ecclesiastical jurisdiction. The holding of the English common law, that a body after burial was the property of no one, encouraged the grisly practice of body snatching—rifting the grave—to which the overcrowded condition of London churchyards and the need (and the lack of legal provision) for cadavers for anatomical study contributed. This practice was ultimately ended by the passage of anatomical, burial and other statutes making it a criminal offense to remove a dead body from the grave and making legal provision for cadavers for anatomical study. These statutes also protect the rights of the next of kin to bury their dead and to prevent the mutilation of the corpse through medical autopsy, or exhumation of a previously interred body, except where public exigency demands otherwise.

In the United States, the courts have uniformly refused to treat a dead body as property in a material sense. However, the need, in particular controversies, for equitable results led to distinguishing between the material property right in the body and the right of survivors' dominion over it. By designating the latter a "quasi-property" right, the courts have been able to protect the sentiments of the survivors from violation arising from undue interference with their right of possession and control of proper disposition of the corpse.

**CORPULENCE**: *see* OBESITY.

**CORPUS CHRISTI**, a city in subtropical south Texas, U.S., a port of entry and seat of Nueces county, overlooks Corpus Christi bay which is separated from the Gulf of Mexico by Mustang and Padre islands. Called the "Naples of the Gulf" because of its shore-line drive at two levels and its T-shaped peninsula extending into the bay, the city resembles a Mediterranean town. It is an industrial as well as a tourist city. The Corpus Christi standard metropolitan statistical area includes Bishop, Port Aransas, Portland and Robstown, all built generally on the same economy as Corpus Christi. Pop. (1960) 167,690; standard metropolitan statistical area (Nueces county), 221,573. (For comparative population figures *see* table in TEXAS: *Population*.)

The history of Corpus Christi falls into four economic periods: (1) ranching under Spanish rule; (2) frontier trade; (3) ranching and farming; and (4) the rise of the petrochemical industry. Prior to 1839 the area was a smugglers' den among Karankawa Indians who were undisturbed by the first serious Spanish explorations. Some ranching activities existed by 1794 and by 1839, when Henry L. Kinney of Pennsylvania established the trading post which became Corpus Christi, Capt. Enrique Villareal endeavored to hold his ranch by force. Pirate, promoter and smuggler, Kinney served as Gen. Zachary Taylor's quartermaster from Corpus Christi to Monterrey during the Mexican war (1846). From this vantage Kinney bought army surplus goods and began a boom with trade to Chihuahua. Kinney's Trading post became an important station on the route to the California gold field via Chihua-

hua but the bubble soon burst to be followed by a disastrous outbreak of yellow fever in 1854. Corpus Christi, so named by 1841, remained a small town from 1854 until about 1920, interrupted chiefly by skirmishes during the Civil War, three severe hurricanes (1874, 1916, 1919), the coming of railroads (1881-1909) and a land boom backed by New York and Boston capital (1888-93).

Discovery of natural gas in 1913 and its later exploitation, opening of the port by a deeper dredged channel in 1926 and discovery of the Saxet oil field in 1939 (the first of several such discoveries in the area) laid the foundation for a city. Population grew from 10,522 in 1920 to 57,301 in 1940, and to 167,690 in 1960, according to the federal census. Continued development of ranching plus new agricultural products (vegetables and sorghum grains), discovery of new raw materials, development of commercial fishing (fish, shrimp and oysters), a growing tourist business, location of a large U.S. naval air station there in 1942, the World War II search for synthetic rubber which stimulated chemical industries, extensive use of government funds for a protective sea wall, a channel and harbour 40 ft. deep with a bridge towering 235 ft. over the turning basin to permit its enlargement and sufficient water for the foreseeable future insured by the Wesley E. Seale dam all contributed to the growth of the city as well as the flat, fertile prairie soils, long growing season (260 to 330 days), rainfall (near 30 in.), and uniform climate. Other raw materials and economic activities include dairying, poultry raising, oyster shell and salt (piped in as brine from an underground dome 60 mi. to the west). From these various raw materials the following are produced: butane, naphtha, other petroleum distillates, formaldehyde, methanol, acetaldehyde, other organic chemicals, carbon black, starch, sugar, caustic soda, soda ash, chlorine, oil well additives and cement. The use of imported ores, permitted by the deep-water port, include bauxite, zinc and cadmium to produce aluminum, refined zinc and cadmium, and sulfuric acid as a by-product.

In the population a strong Mexican influence is mingled with the old south, the north and the Texas range and with strong strains of Irish, German, Bohemian and Czech. Incorporated in 1852, the city adopted the city-manager form of government in 1945. The public school system includes Del Mar junior college (founded 1935) with separate liberal arts and technical divisions. There are a number of private and parochial schools and a denominational college. La Retama public library, study groups (art, music, literature, drama), a Civic Music association, the Corpus Christi Symphony orchestra, numerous playgrounds and parks, a yacht basin, the Junior museum, Exposition hall, Memorial coliseum and Centennial Art museum provide opportunity for recreation and cultural activities.

(N. M. T.)

**CORPUS CHRISTI, FEAST OF**, a festival of the Western Christian Church in honour of the Real Presence of Christ in the Eucharist, observed on the Thursday after Trinity Sunday. The institution of this feast is due to Blessed Juliana, prioress of Mont Cornillon near Liège (1222-58), whose veneration for the Blessed Sacrament was intensified by a vision and who persuaded Robert de Torote, bishop of Liège, to order the festival for his diocese in 1246. It did not spread, however, until 1261 when Jacques Pantaléon, formerly archdeacon of Liège, became pope as Urban IV. By a bull of 1264 he ordered the whole church to observe the feast, which to that time had been practically confined to the diocese of Liège; a new office (still in use) was written for the festival by St. Thomas Aquinas. Because perhaps of Urban's death soon afterward (Oct. 2, 1264) his order was ignored in most countries until after its confirmation by Clement V at the Council of Vienne in 1311. By the middle of the 14th century the festival had found general acceptance, and in the following century it became in effect the principal feast of the church.

Urban's bull made no mention of a solemn procession or the elevation of the Host for the adoration of the faithful; rather the stress was laid on reverence for the Holy Sacrament as a whole. The procession, now its most prominent feature, became a gorgeous pageant in which sovereigns and princes took part, as well as magistrates and members of trade and craft guilds. In the 15th century the custom became almost universal of follow-

ing the procession with the performance of miracle plays and mysteries, generally arranged and acted by members of the guilds who had formed part of the pageant.

The rejection of the doctrine of transubstantiation at the Reformation naturally involved the suppression of the festival, as a religious observance, in the Reformed churches. See also CHURCH YEAR.

**CORREGGIO** is the name universally given to ANTONIO ALLEGRI (c. 1494–1534). He was one of the half-dozen greatest masters of painting of the High Renaissance in Italy, and, in his later works, a forerunner of the baroque style. In the 16th century he was already known as "the painter of the Graces," and although his works were concentrated at Parma and in a few neighbouring cities, he was early considered worthy of being named in the company of Raphael, Michelangelo, and Titian.

His father was Pellegrino Allegri, a tradesman of at least comfortable circumstances, living at Correggio, a small city in the territory of Modena. Antonio was born at Correggio, the town that gave him his name, probably not long before Aug. 30, 1494, and died there on March 5, 1534. He was not, as it is often alleged, self-taught in his art, for the internal evidence of his work refutes the theory, showing as it does a knowledge of optics, perspective, architecture, sculpture, and anatomy. His initial instruction came probably from his uncle, Lorenzo Allegri, a painter of moderate ability, at Correggio, and from Antonio Bartolotti (named Tognino); afterwards he was probably a pupil of Francesco Bianchi-Ferrari at Modena (about 1503) and pursued further studies at Mantua during the period in which Andrea Mantegna, who died in 1506, was succeeded as court painter by Lorenzo Costa. Although Correggio's early works are pervaded with his knowledge of Mantegna, his temperamental sympathy lay more with Leonardo, who had a commanding influence upon almost all of the Renaissance painters of northern Italy. Where Mantegna uses line, Correggio's work shows his characteristic chiaroscuro: softness and shade and light—the quality that came to be known in the 18th century as the "Correggiosity of Correggio." His

time was divided between Parma and his home town, but that he early visited Rome and came under the influence of the great frescoes of Michelangelo and Raphael is fairly certain. An early tradition records that he completed the decoration in Mantegna's family chapel in the church of S. Andrea at Mantua after Mantegna's death; and it seems certain that the two *tondi* located there are Correggio's: "Madonna and Child with St. Joseph, St. Elizabeth, and the Infant St. John the Baptist" and "Entombment of Christ."

A group of devotional pictures, which became increasingly luscious in colour, antedate the first securely documented painting by Correggio, the altarpiece in the Dresden collection called the "Madonna of St. Francis," which was commissioned for S. Francesco at Correggio in 1516. The most important of these are "The Marriage of St. Catherine" (Detroit), the "Nativity" and "Adoration of the Kings" (Brera gallery, Milan), and "Christ Leaving His Mother" (National gallery, London).

Other paintings of Correggio's youth are the "Arrest of Christ," a triple altarpiece entitled "Repose in Egypt, with SS. Bartholomew and John"; and "Madonna, Child and St. John" (which in 1966 was stolen from the Art Institute of Chicago and subsequently returned having suffered relatively minor damage).

His mature style, however, only emerged with his first commission for Parma, the ceiling of the abbess' parlour in the convent of S. Paolo, which was probably executed about 1518–19. Although there are echoes in this work of Mantegna's frescoes in the Castello at Mantua, it was wholly original in conception. The ceiling was conceived as a trellis in 16 compartments, with an oval gap in each revealing pairs of children who form an allegory of human activities, and each trellis terminates in a lunette in *grisaille* with classical personifications often taken from antique coins. This learned humanist program, assimilated to art with extraordinary perfection, was one of the last of its kind planned for a sacred building prior to the reforms within the church which were urged by popes from Julius II onward. The abbess, Giovanna de Piacenza, secured for Correggio another important appointment to decorate the cupola of S. Giovanni Evangelista (1520–23), which with Correggio's other great decorative works were all made for Parma. Here, in the "Ascension of Christ," the Redeemer is surrounded by the twelve apostles and the four doctors of the church, supported by a host of wingless cherub boys amid the clouds. The "Ascension of Christ" was followed by the decoration of the apse of the same church, of which only the principal of the group, entitled "Coronation of the Virgin," survives in the Parma gallery, the remainder being destroyed in 1584. In the cupola is St. John seeing the vision of the Ascension; this was still in the High Renaissance tradition and owed much to Michelangelo.

In the cupola of the cathedral (1526–30), with the "Assumption of the Virgin," Correggio anticipated the baroque and treated the whole field as a single pictorial unit of vast proportions, equating the dome of the church with the vault of heaven. The astounding boldness of scheme in these works, especially as regards their audacious foreshortenings—the whole mass of figures being portrayed as in the clouds, and as seen from below—was startling and made a profound impression at the time. The violent foreshortenings were not the object of unmixed admiration: some satirist termed the group a "mass of frog legs." This, however, was not the opinion of Titian who on seeing the pictures and finding them lightly esteemed by the local dignitaries is reported to have said, "Reverse the cupola and fill it with gold, and even that will not be its money's worth." But its influence was greatest a century later, in the Roman baroque movement, when its decorative implications were first carried further by Giovanni Lanfranco, himself a native of Parma.

Correggio had more imitators than pupils. Only a few can with certainty be said to have studied with him: his son, Pomponio (b. 1521); Francesco Capelli; Giovanni Giarola; Antonio Bernieri; and Bernardo Gatti, who ranks the best of all.

The remainder of Correggio's most famous works, the dates of few known with certainty, fall into three groups: the great altarpieces (and a few other large religious compositions); exquisite

"MADONNA OF THE BASKET" BY CORREGGIO. IN THE NATIONAL GALLERY, LONDON

small works of private devotion; and a handful of mythological subjects of a lyrically sensuous character. The altarpieces are among those landmarks of art which have acquired affectionate nicknames. The "St. Sebastian," the "Night" (finished about 1530) and the "St. George" (1530-32) are among those which are in the gallery at Dresden in Germany, but the "St. Jerome" (1527-28) and the "Madonna della Scodella" (1528-30) remained in the Parma gallery, as did the large "Deposition" and the "Martyrdom of St. Placidus and Others," which are among Correggio's most remarkable inventions. The "St. Jerome" in particular combines an intimate and domestic mood with astonishing softness and beauty of paint texture, and includes types of feminine beauty of ideal loveliness.

BY COURTESY OF GEMÄLDEGALERIE ABT. ALTE MEISTER

"THE MADONNA OF ST. FRANCIS," ALTARPIECE BY CORREGGIO; EARLY 16TH CENTURY. IN THE DRESDEN (GER.) GALLERY

This intimate and homely poetry was carried through into the small devotional works such as the "Madonna of the Basket" (National gallery, London), "La Zingarella" (Naples) and the "Virgin Adoring the Child" (Uffizi, Florence). The most famous of the devotional pictures which explored this vein of ideal feminine loveliness is the larger "Marriage of St. Catherine" (Louvre museum, Paris).

Correggio's technique, which was the reverse of linear and in which the paint seems to have been lightly breathed onto the forms, achieved its most remarkable results in the mythologies. The earliest were probably the "Antiope" (Louvre) and the "Education of Cupid" in the National gallery, London; the others all belong to his last years—the "Danaë" (Borghese gallery, Rome), the "Ganymede" and "Io" (both at Vienna), the battered "Leda" in Berlin, and the two allegories of Vice and Virtue painted for Isabella d'Este (in the Louvre). In these the sensuous character of the subject matter is enhanced by the quality of the paint and these pictures carry this kind of sensibility to the limits to which it can go without offense.

Correggio's drawings are spirited and audacious and always made with paintings in view. The intimate and most "precious" quality of his more widely distributed works has sometimes led him to be considered as an artist of less than the highest flight—

a view which follows Giorgio Vasari who regretted that Correggio had never had the advantages of study in Rome. But this impression is redressed by the works which remain at Parma. Although his influence can be detected in later Parmese painting, and counts for something in the Mannerist style of Parmigianino, Correggio had no direct pupils who deserve mention. His decorative ideas were taken up by the baroque painters of the 17th century, he became almost a tutelary deity of the French rococo style, and his great altarpieces were among the works most abundantly copied by the traveling artists of the 18th century during their years of study in Italy.

**CORREGGIO, DA**, Italian feudal family who were lords of Correggio, near Reggio Emilia, from the 11th to the 17th century. During the 13th century, as leaders of the Guelfs, they came to dominate the politics of Parma, and in 1303 Ghiberto da Correggio was acclaimed lord of the city, which he ruled until 1316. In 1341 his son Azzo, a friend of Petrarch, who dedicated to him the *De remediis utriusque fortunae*, recovered control of Parma, only to sell it again three years later to the Este family of Ferrara. Correggio itself, however, remained independent, being raised to the rank of countship in 1452 and to that of principality in 1616. Shortly afterward, in 1630, Siro da Correggio was condemned by the Holy Roman emperor Ferdinand II to pay a heavy fine for minting bad coin; unable to raise the sum he was forced to cede Correggio to the Este of Modena in 1634. The family came to an end with the death of Camillo in 1711.

**CORREGIDOR**, a rocky island at the entrance of Manila bay, Republic of the Philippines, famous for a battle of U.S. and Filipino forces against overwhelming numbers of Japanese during World War II.

Corregidor was recognized as a natural fortress protecting Manila bay by the Spanish, who constructed fortifications on it in the 18th century. After the Spanish-American War the United States made it a military station. In the early days of World War II, after the fall of Bataan in April 1942, Corregidor was the last outpost of organized resistance in the islands. For 27 days its forces, under Lieut. Gen. Jonathan M. Wainwright, repelled all efforts to dislodge them from the elaborate system of tunnels and emplacements built after the Spanish-American War, but were finally forced to capitulate on May 6, 1942, to Japanese Lieut. Gen. Masaharu Homma. U.S. forces regained the island in 1945.

See also **WORLD WAR II: The War in the Pacific**.

**CORRELATIVE** generally denotes the terms or partners of a relationship. A relationship requires at least two terms between which it holds, and they are said to be correlative terms. Thus "cause" and "effect" exemplify one kind of relationship; "teacher" and "pupil," another; "north" and "south," yet another relationship. The terms in each of these pairs are accordingly called, in logic, "correlative" terms. The expression has also been extended to propositions which express the same relationship from different points of view. Thus *S is north of P* implies *P is south of S*. They are simply correlative propositions.

**CORRENS, KARL ERICH** (1864-1933), German botanist, was one of several scientists who, near the end of the 19th century, independently and almost simultaneously rediscovered Mendel's laws (see **MENDEL, GREGOR JOHANN**). He was born at Munich on Sept. 19, 1864, and educated in the same city. After graduating from the university in 1891, he continued his studies, working under Karl von Naegeli, Gottlieb Haberlandt and Wilhelm Pfeffer. In 1892 he became *Privatdocent* of botany in the University of Tübingen and was promoted to a professorship in 1897. In 1902 he was transferred to Leipzig and in 1909 to

Münster. He was appointed director of the Kaiser Wilhelm Research Institute for Biology and professor of the University of Berlin in 1914, and held that position until his death on Feb. 14, 1933.

Correns started his research work by investigation of the cell structure and the growth of the cell wall. Later he turned to the study of the reproduction of mosses. Mendel's law attracted his attention to the problems of genetics, and in this field he achieved so much that his eminence was recognized throughout the world. He was especially interested in hybridization and in the most difficult problems of inheritance in plants, including the so-called anomalous inheritance of variegation. The study of self-sterility in a number of plants culminated Correns' scientific activity.

**CORRESPONDENCE, COMMITTEES OF.** These were committees originally appointed by the legislatures in the American colonies to correspond with colonial agents in England. They assumed new functions on the eve of the American Revolution, providing colonial leadership and aiding intercolonial co-operation. Their emergence as agencies of colonial discontent was prompted by Samuel Adams who, at a Boston town meeting, Nov. 2, 1772, secured the appointment of a 21-man committee to communicate with other towns in Massachusetts. Similar groups had appeared in some 80 towns in the colony by Jan. 1773. These committees were all local in character. The emergence of intercolonial committees followed the suggestion of the Virginia house of burgesses which, on March 12, 1773, appointed 11 men, including Patrick Henry and Thomas Jefferson, as a committee for intercolonial communication. By the end of 1773, eight other American colonies had followed Virginia's example.

The committees played a major role in promoting unity against England and in calling together in Sept. 1774 the first continental congress (*q.v.*), a majority of whose delegates were committee members. With the breakdown of royal control these earlier committees were superseded by committees of safety, but the colonial experience subsequently was seen in the introduction of correspondence committees as a common system of early party organization in the United States. (N. E. CV.)

**CORRESPONDENCE EDUCATION**, often called home study and sometimes postal tuition, is a method of providing education for nonresident students who usually receive lessons and exercises through the mails and upon completion return them for grading. Sometimes described as the learn-by-mail method, correspondence education is characterized by this exchange or feedback of information between the student and his instructor, with subsequent examinations. It is primarily for adults and is extensively used by persons pursuing nonresident study, by business and industry in training programs, by men and women in the armed forces, and by the governments of many nations to advance the competence of their people.

Although a part of adult or continuing education, it should not be confused with self-directed private study, great books courses, or extension classes. Originally the "poor man's university" and largely confined to vocational subjects, it now also embraces liberal, applied, and professional courses from the elementary to the postgraduate level. There are special programs for the blind and deaf and for persons otherwise handicapped. It supplements other forms of education and makes independent study programs readily available.

**History.**—The correspondence movement, an offshoot of the Industrial Revolution, had its beginnings in the mid-19th century, evolving from universities and various educational projects, particularly lyceums (see LYCEUMS AND CHAUTAUQUAS). Fortunately, as industrial and urban development began to require an educated trade and working class, improved printing and postal services made home study practicable as well as desirable. Learning was being advanced by books and libraries, newspapers, charity schools, debating societies, the Sunday School movement, scientific groups, the YMCA, and workingmen's colleges and institutes. The ferment for economic and social betterment resulted in correspondence and extension courses in Great Britain, Germany, and the United States.

In 1840, in Bath, Eng., Isaac Pitman reduced the principles

of his shorthand course to fit small cards. He sent these to students who were requested to transcribe into shorthand passages of the Bible and return these to him by the new penny post for correction. In 1856 Charles Toussaint, a Frenchman, and Gustav Langenscheidt, a German writer, founded in Berlin a school for the teaching of modern languages by correspondence. In 1867 James Stuart of Trinity College, Cambridge, delivered off-campus lectures which are regarded as the beginning of university extension (*q.v.*), a movement that contributed much to correspondence education. Skerry's College, a business school in Edinburgh, Scot., began postal instruction in 1880; and this was followed within a decade by several correspondence schools in England.

The real development of correspondence instruction, however, followed the popularization of extension classes, not in Europe but in the United States. One of the leaders there was Illinois Wesleyan University, which in 1874 began a series of undergraduate and graduate courses that could be pursued *in absentia*.<sup>1</sup> Various degrees were offered for adults, primarily ministers and teachers, and branches of the nonresident department were established in Canada and Great Britain. Forty courses were required for the bachelor's degree and course examinations were proctored in distant communities by distinguished citizens. Final examinations were conducted on the campus of the university. Illinois Wesleyan's program was discontinued in 1910.

Meanwhile the Methodist annual assembly at Fair Point on Lake Chautauqua, N.Y., came into prominence as an educational and recreational centre. In 1879 a school of languages was organized there by a young professor of Hebrew, William Rainey Harper (*q.v.*). When the summer session was over a number of students expressed a desire to continue studying through the academic year and they asked their teacher to outline a course of study and advise them by mail. Harper agreed and this was the beginning of the home study program announced by the *Chautauqua Assembly Herald* on Aug. 8, 1882. Harper became the first president of the University of Chicago in 1891, and he at once established a correspondence division. It offered college courses for credit by mail, and the work of this division was integrated with other divisions of the university. The Chautauqua-Chicago idea rapidly spread to other universities, notably the University of Wisconsin under the leadership of Charles Van Hise, who had served as an extension teacher at Chicago.

The growth of university extension and correspondence instruction in the United States was greatly advanced by the passage of the Smith-Lever Act in 1914, which provided for cooperative agricultural and home economics extension work (see LAND-GRANT COLLEGES AND UNIVERSITIES).

Private correspondence schools in the United States generally followed the efforts of Thomas J. Foster of Pennsylvania to prevent accidents in coal mines. In 1870 he began publishing the *Shenandoah Herald*, later called the *Mining Herald*, and this newspaper featured articles on mine safety and advocated legislation requiring mine inspections and certificates of competency for inspectors and superintendents. After July 1, 1886, such certificates were required in Pennsylvania and, in the absence of courses and text materials, Foster began a question and answer column in his newspaper to help officials qualify for certificates. Soon pamphlet lessons were printed on mining and other subjects and a staff was assembled to grade examinations. Foster's school, which began operations in 1890 with the incorporation of the Colliery Engineering Company, became the International Correspondence Schools of Scranton.

Independent of developments in the United States and Great Britain but probably under the influence of the work of Toussaint-Langenscheidt, the Rustinsches Fernlehrinstitut was founded in Berlin in 1894 to prepare students through correspondence for university entrance examinations. About the same time Hans

<sup>1</sup>The Society to Encourage Studies at Home had been organized in Boston in 1873, but it soon disbanded because it failed to adapt instruction to the needs and abilities of the students. Later, in 1883, a Correspondence University, consisting of teachers from various institutions, was founded at Ithaca, N.Y. It was designed to supplement the work of other educational institutions by instructing persons who, for whatever reasons, were unable to attend them. Although widely acclaimed, this venture, too, failed.

Hermod of Sweden found it necessary to give instruction by letter to students who had moved from Malmö. This was the beginning of the Hermods Schools, now Hermods-NKI Skolan, which has offered correspondence courses since 1898.

Correspondence education was initiated in Russia during the latter half of the 19th century by educators and cultural-education societies and groups such as the Society for the Promotion of Technical Knowledge and the People's Universities. Leaders of a conference in 1908 advocated organized correspondence courses and preparation of students for higher education, proposals later incorporated in the extensive system of part-time education developed in the U.S.S.R. From the beginnings outlined, the new medium of education spread rapidly to other parts of Europe, and to Australia, New Zealand, Canada, South Africa, and Japan.

**Growth and Development.**—The most prominent institutions offering correspondence instruction in both Europe and the United States in the second half of the 20th century have been the private correspondence schools, independent institutions that are usually operated for profit. A very wide range of subjects is available, with particularly heavy emphasis on vocational and trade courses, and academic subjects at all levels. In the United Kingdom courses are offered leading toward external degrees of London University and other educational qualifications such as the general certificate of education. In the United States state departments of education award high school diplomas to correspondence students and others on the basis of equivalency examinations; and the state of New York has established a program of equivalency examinations at the college level. Students in accredited schools are eligible for government loans and for veterans-GI educational benefits, the same as college students.

Perhaps the greatest area of growth for the private correspondence schools in the 1960s was in special courses for particular businesses and industries; many firms paid all or a substantial part of the cost of instruction through tuition reimbursement plans for their employees.

Universities, which contributed to the origin and development of correspondence instruction, have continued to use the method in their extension activities. The University of South Africa at Pretoria from 1951 employed the correspondence method exclusively in its graduate degree program.

Various governments also sponsor programs of correspondence instruction, particularly for armed forces personnel. In the United States, for example, the armed services have provided a large number of correspondence courses for reserve officers and men, and the Armed Forces Institute operates an enormous program for persons in the military service. The British forces correspondence course scheme is available to all ranks in her majesty's armed forces. It provides courses leading to external degrees of London University, to professional and other vocational qualifications, and courses for purely cultural study.

Education in the Soviet Union includes numerous correspondence courses, and enrollments have increased greatly since the Educational Reform Act of 1958. Correspondence study in the U.S.S.R. is usually combined with resident instruction and on-the-job training. The entire network of correspondence schools and institutes, and correspondence divisions of universities and other educational institutions, encompassing general elementary, secondary, and higher education as well as vocational and technical training, is fully integrated with the state educational system. This plan is followed in general by other Communist countries.

Australia was the first country to demonstrate on a large scale that it is possible to offer complete primary and secondary education for children not in resident schools. In Australia all the state departments of education have since the early decades of the 20th century provided highly organized services of correspondence instruction for children of primary and secondary school age. The courses, which cover the entire curriculum, are supplemented by traveling libraries and exhibitions, correspondence school magazines, radio and, in metropolitan districts, television features and other means, including occasional regional and national meetings. For older students technical courses have been extensively developed, and some university courses are available.

A similarly comprehensive governmental service operates as a part of the public school system in New Zealand. Several Canadian provinces offer correspondence instruction throughout grade school and some also provide courses for adults.

Correspondence education in an official school system comparable with that in Australia also has been practised in Sweden, particularly for students in remote areas. Other countries, for example France, provide courses for children and adults who wish to complete requirements for elementary, secondary or vocational school certificates. In the United States, where public schools have not developed such comprehensive programs, many high schools enrich their curriculums and meet special requirements of students through supervised correspondence programs supplied by universities and private schools. Correspondence instruction is well advanced in Japan and its use is proving effective in Latin America and in many nations of Africa and Southeast Asia.

In many countries adult education agencies, voluntary associations, industrial firms, and government departments offer or utilize correspondence programs. Some professional bodies provide courses for their members, and many students use correspondence courses to prepare for professional examinations. Refresher courses are quite popular. The National Safety Council, American Hotel and Motel Association, American Association of Medical Record Librarians, American Society for Metals, International City Managers' Association, and similar groups offer courses to their members and others interested in the field.

**Subjects and Methods.**—Subjects in virtually all fields are offered by private correspondence schools, industry, government agencies, and universities. They run the gamut from accounting, agriculture, and art to salesmanship, wildlife management, and zoology. Many subjects are offered which are not generally given in residence schools such as camera repair, floristry, locksmithing, gemology, and safety. Standard elementary, secondary school, and college courses, special programs in citizenship and for teacher certification, and courses in electronics, data processing, engineering, automobile mechanics, hotel-motel management, interior decoration, languages, business subjects, real estate, photography, and writing are popular. If a course is not offered and there is a demand, it will be prepared.

Instruction may be wholly by correspondence or by a combination of home study and resident seminars or laboratory work. It may include programmed learning materials, sound records or tapes, slides, films, teaching machines, computers, and the use of telephone, radio, including two-way radio with each student using a transceiver as in Australia, and television. Courses often include kits of tools or instruments and materials to be processed as well as texts and study guides. Courses in braille and on records are available for the visually handicapped. Many schools offer guidance and placement services. Programs sponsored by schools and other public agencies often include special provisions for periodic home visits by teachers, occasional student get-togethers at local centres, or series of short-term residential school sessions for school-age children, as in New Zealand, or for discussion groups or study circles, as in Rumania.

**Accreditation and Regulation.**—A number of professional associations have emerged over the years, concerned with promoting and improving correspondence education. In the United States, the American Society for the Extension of University Teaching (ASEUT) was organized in Philadelphia in 1890; it brought lecturers from England to America and sought to carry out teaching as a private enterprise. ASEUT gradually declined and was succeeded by the National University Extension Association (NUEA), founded at Madison, Wis., in 1915, through which public and private universities and colleges cooperate. The 60-odd NUEA members that offer home study courses belong to the Correspondence division of the association. NUEA publishes criteria and standards for correspondence work. Member institutions are accredited by the regional accrediting associations.

In the private correspondence field, the National Home Study Council (NHSC) of Washington, D.C., was incorporated as a non-profit educational association in 1926. This organization grew out of a study of correspondence schools, lyceums, and chautauques.

made by John S. Noffsinger under the auspices of the Carnegie Corporation in 1924. The NHSC Accrediting Commission is recognized by the U.S. Office of Education, and it has established standards to maintain academic quality and sound business practices. Council membership is based on accreditation. In the mid-1960s, the Carnegie Corporation financed a study of public and private correspondence education through the American Council on Education and the National Commission on Accrediting.

In Great Britain efforts to coordinate, regulate, and advance correspondence instruction have been undertaken by the Association of British Correspondence Colleges formed in 1955. The European Council for Education by Correspondence, founded at Leiden, Neth., in 1962, has proven an effective agency for the advancement of quality home study schools in Western Europe. The International Council on Correspondence Education was organized in Victoria, Can., in 1938. A membership organization, it convenes in different parts of the world every four years. The growth of this organization and the concern of UNESCO indicate the potential of correspondence education as a part of overall efforts to provide educational opportunities for all.

(D. A. Lo.)

**CORRÈZE**, an inland *département* of central France, formed from the southern portion of the ancient province of Limousin (q.v.), is bounded north by Haute-Vienne and Creuse, east by Puy-de-Dôme, southeast by Cantal, south by Lot and west by Dordogne. Pop. (1962) 237,926. Area 5,888 sq.km. (2,273 sq.mi.). It is situated on the western margin of the Massif Central (q.v.) and is largely undulating plateau country composed of granite and other crystalline rocks that give an impermeable surface and infertile, acid soils. The highest ground, in the north, is part of the plateau of Millevaches, which separates the drainage basins of the Loire and Garonne. Most of the *département* is drained southwest by the Dordogne and by the Vézère and its tributary the Corrèze. In its lower, western portion the softer sedimentary rocks that flank the Massif Central form a marginal depression, the basin of Brive, with rich if clayey soils. In this undulating, verdant lowland, mixed farming is practised on small holdings, with maize, a wealth of fruits, potatoes and other vegetables and the rearing of a variety of livestock. The vineyards that were formerly important were largely replaced by fruit trees after the Phylloxera infestation at the end of the 19th century. The crystalline uplands are tracts of much poorer farming where the traditional grain crop was rye, not wheat or maize. The higher

parts provide only summer grazing and there is generally much heath remaining, but the lower tracts of undulating plateau form a *bocage* (q.v.) countryside of small, hedge-bounded fields, devoted to grass and other fodder crops. Intensive cattle rearing is the modern basis of the rural economy. There is no longer much cultivation of grain, and the chestnut woodlands that were once so important are neglected and ravaged by disease.

Apart from scattered brick- and tileworks, and leather and agricultural industries in the market towns, there is little manufacturing in the *département*. At Tulle (q.v.), which gives its name to a fine net, is a government firearms factory.

Corrèze is divided into the *arrondissements* of Tulle, Ussel and Brive. It lies in the archdiocese of Bourges and the educational division (*académie*) of Clermont-Ferrand and comes under the jurisdiction of the Limoges court of appeal. Tulle, the capital, in the centre of the *département* and Brive, or Brive-la-Gaillarde (q.v.), near its western border are the chief towns. There are Romanesque churches at Uzerche, Aubazine, Beaulieu-sur-Dordogne, Meymac and Vigéois. Uzerche and Treignac, with extensive remains of their medieval fortifications, and Turenne, dominated by the ruins of its castle, are picturesque towns.

(AR. E. S.)

**CORRIB, LOUGH** (LOUGH CORRIB), a lake chiefly in County Galway, Republic of Ireland, is located on the western edge of the central Irish lowland. It is drained southward by the Corrib river through the city of Galway. Varying in width to a maximum of 10 mi. and with a total length of 29 mi., Corrib is the third largest lake in Ireland. On the west its shores form the fringe of Connemara (q.v.), and peat bogs of vast extent, in part due to the infilling of the lake, alternate with farmed ridges of glacial drifts. To the east there are also large bogs and limestone outcrops, of which some are bare rock with rough woodlands and others good pastures of farmed lands. The lake provides brown-trout fishing and facilities for pleasure boating. When Galway's Eglinton canal was built (1848-57), steamboats went to a quay near Oughterard. The drainage was improved by schemes in 1846-50 and far more effectively in 1955-59.

(T. W. Fr.)

**CORRIENTES**, a province of the Mesopotamia region of northeastern Argentina, is bounded in the north and west by the Paraná river, which separates it from Paraguay, and in the east by the Uruguay river, which separates it from Brazil and Uruguay. Its area is 34,054 sq.mi. Pop. (1960) 537,284. The north of Corrientes consists mainly of a low-lying plain with swamps and lagoons, the largest lagoon being the Estero del Iberá. To the south there are fine natural pastures and woods in the rolling uplands and abundant streams. The climate is hot and humid in the north, subtropical in the southern hills, with hot, rainy summers and mild winters. The mean annual temperature is about 71° F. The principal activity is the raising of cattle and sheep. Among the chief crops are maize (Indian corn), rice, cotton, tobacco and flax. Yerba maté and tung are grown in the north, near the Misiones border. The province is especially noted for its citrus fruits. Provincial exports include cattle, hides, timber and firewood, oranges and quarried stone. Manufacturing industries are small, the most numerous being sawmills and tanneries.

The principal town and capital is Corrientes (q.v.), an important port on the Paraná for steamers plying between Buenos Aires, the upper reaches of the Paraná and the Paraguay river. Passengers traveling upstream usually change into vessels of smaller draft at Corrientes. This is the most densely populated district. Other ports on the Paraná are Goya (pop. [1960] 30,011), which is on a side channel of the main river and is a flourishing commercial centre exporting pastoral and agricultural products; Empedrado; Bella Vista; and Esquina, which exports timber and firewood. Small ports on the Uruguay river are Monte Caseros, Paso de los Libres and Santo Tomé. For generations cattle were smuggled across this upper stretch of the Uruguay, when the difference between prices on the Argentine side of the river and the Brazilian side made it profitable. The rivers provide the main means of communication in northeastern Argentina, but the chief towns in the province are connected by railway and road. A railway from the town of Corrientes runs southeastward via the inland towns of

Mercedes and Curuzú Cuatiá to Buenos Aires, a distance of 660 mi., taking a day and a half. Another railway goes north from Monte Caseros, running close to the Uruguay river into Misiones on the way to Asunción, Parag. Branch lines connect with Goya and with the inland towns of General Paz and Mburucuyá, both of which lie in a particularly fertile northern district of the province.

(G. E. P.)

**CORRIENTES**, a river port and capital city of Corrientes province in northeast Argentina. It lies on the left bank of the Paraná river, 20 mi. below the confluence of the upper Paraná and Paraguay rivers and 667 mi. N. of Buenos Aires by rail. Pop. (1960) 103,999. The city was founded in 1588 by Torres de Vera, who built a fort named San Juan de Vera de las Siete Corrientes ("seven currents") for the seven rapids in the river just upstream. It is a transshipment point for river traffic because vessels of shallower draft must be used for navigating the upper Paraná and the rivers of the Chaco. Its favourable situation in relation to the river basins has made Corrientes an important commercial and industrial centre. Meat-freezing works, tanneries, sawmills, textile plants and vegetable-oil factories in the city reflect the agricultural and pastoral wealth of its neighbourhood. Among the city's administrative buildings the government palace is noteworthy.

Corrientes is the seat of a bishop in the archdiocese of Paraná, and has a Renaissance-style cathedral (Las Mercedes). The church of La Cruz is a pilgrimage centre where the 16th-century cross of Torres de Vera is venerated.

Corrientes is the terminus of the railway from Entre Ríos province and branch lines serve the productive area of northern Corrientes province. Ferries link it with Barranqueras and the Chaco province on the opposite bank of the Paraná, and there are airline services to Buenos Aires, Rosario, Arg., and Asunción, Parag.

(G. J. B.)

**CORROSION AND OXIDATION OF METALS.** The term corrosion may be used to denote a chemical change in which metal passes from the elementary to the combined condition; examples include the formation of scale (oxide) on steel heated in air and of rust (hydrous oxide) on iron exposed to water or damp air.

To the pure scientist, corrosion reactions should form an essential division of chemical kinetics; they follow well-established laws, often simple and capable of rational interpretation, but differing somewhat from the laws which receive more prominent treatment in chemical textbooks.

In industry, corrosion processes are sometimes brought about intentionally, as in manufacturing the pigment white lead by the corrosion of metallic lead. More often, they are undesired changes involving damage and expense.

The damage caused by corrosion is enhanced whenever attack is concentrated upon small areas. Intense localized attack ("pitting") often occurs under conditions intermediate between those which produce general corrosion and those which confer complete immunity.

Thus, inadequate protective measures may actually accelerate penetration, leading to rapid perforation of some pipe or containing vessel. On certain materials, the boundaries of the grains are more susceptible than the interiors, and such substances, subjected to a static stress in a corrosive environment, may develop intergranular cracking, leading to failure; certain aircraft alloys, after incorrect heat treatment, are prone to this "stress corrosion cracking."

Where metal is subjected to alternating stresses in a corrosive environment, the most susceptible portions may be, not the intergranular boundaries, but disorganized matter produced along slip planes; thus, "corrosion fatigue" arises.

Structural members subjected to alternating stress may crack in a corrosive environment at stress ranges well within what would be the limits of safety in noncorrosive conditions.

**Direct Oxidation.**—An oxide-free surface of iron or copper exposed to dry air at ordinary temperatures soon becomes covered with an invisible oxide film, which isolates the metal from oxygen, so that its growth becomes continuously slower. The progress of

oxidation—very rapid during the first few minutes, but steadily slackening—can be followed by gravimetric, optical or electro-metric methods.

If the metal is gently heated in air, the film soon becomes thick enough to produce interference tints (see *LIGHT: Waves and Interference: The Colours of Thin Plates*). At high temperatures scale too thick to give interference colours is quickly formed on iron and copper. Even here the rate of oxidation declines as the film thickens, provided that the scale remains continuous; but thick scale is likely to flake off, particularly under conditions of bending, scraping or fluctuating temperature; to withstand oxidizing conditions at very high temperatures, a material must be chosen which produces a film that is protective while still thin.

At least three equations have been established for expressing mean film thickness,  $y$ , at time,  $t$ ; namely,

parabolic equation,  $dy/dt = k_1/y$  or  $y^2 = K_1t + K_2$ ;

logarithmic equation,  $dy/dt = k_2e^{-k_3y}$  or  $y = K_3 \log(K_4t + K_5)$ ;

rectilinear equation,  $dy/dt = k_4$  or  $y = K_6t + K_7$ .

( $K_1 = 2k_1$ ;  $K_3 = 1/k_3$ ;  $K_4 = k_2k_3$ ;  $K_6 = k_4$ . All  $K$ 's and  $k$ 's represent constants independent of time but varying with temperature.)

Parabolic thickening occurs on copper heated in air at high temperatures (Norman Pilling and R. E. Bedworth, 1923); also on iron, nickel and tungsten, and on nickel-chromium alloys. It is generally attributed to the migration of metallic cations and electrons outward through the film to meet the oxygen, and the value of the constant  $k_1$  is related to the electrical properties of the film substance by the equations of C. Wagner (1933, 1952). Enhanced resistance to oxidation is obtained by introducing into iron alloying constituents in which either the electronic conductivity or the cationic conductivity is low (see *ELECTRICITY, CONDUCTION OF: Conduction in Solids: Ionic Conduction*). Even small percentages of impurities may suffice to alter the nature or abundance of defects in the crystal lattice of the metal or of the oxide film in such a way as to affect the corrosion resistance markedly (E. Gulbransen, 1956). The improved oxidation resistance of iron-aluminum alloys is probably connected with the low electronic conductivity of an alumina film, while that of steels containing chromium has been attributed by some authorities to the low cationic conductivity of chromic oxide. (In practice, a layer of aluminum alloy is produced on fire bars and heat-treatment boxes by heating in a mixture containing aluminum powder, as in the calorizing process.)

The presence of sulfur compounds in the atmosphere accelerates attack by increasing the number of lattice defects in the scale; the products of combustion of coal rich in sulfur cause far more wastage than that of cleaner coal. Again, air containing hydrogen sulfide produces on copper at ordinary temperatures the same sequence of interference tints which, in pure air, occur only when the metal is heated.

At relatively low temperatures, where parabolic thickening is (in absence of sulfur compounds) unimportant except in the opening stages, film growth may occur on iron or copper according to the logarithmic law. A rectilinear growth was found on zinc exposed to London air at ordinary temperatures (W. H. J. Vernon, 1923) and logarithmic growth when it was exposed to relatively pure air over the temperature range 25°–400° C. (Vernon, E. I. Akeroyd and E. G. Stroud, 1939). Rectilinear thickening may be caused by the fact that the film substance is sometimes in its nature porous; e.g., where it is an oxide which occupies a volume smaller than the metal destroyed in producing the oxide.

The cause of logarithmic growth is a matter still under discussion.

**Corrosion by Liquids.**—Wet corrosion may be divided into: (1) film-forming reactions; and (2) others. Where a solid film is formed over the metal, the rate of thickening usually dies away with time, sometimes according to the parabolic law given above. L. B. Parsons (1925) studied the behaviour of several metals toward iodine dissolved in various organic solvents. When the iodide of the metal under test was soluble in the organic liquid chosen, corrosion continued apace; when an insoluble solid iodide

appeared on the surface, the corrosion was unimportant.

Since most metallic oxides are sparingly soluble in water, the attack on heavy metals by pure water containing oxygen would be expected to be slow; this is found to be the case, although sometimes the attack is intensified through localization, and cannot then be neglected.

Where salts are present in the water, electrochemical corrosion becomes possible, often leading to soluble substances as anodic and cathodic products; in such cases no film is produced, and the corrosion continues unchecked. For instance, if rolled steel covered with broken oxide (mill scale) is placed in a salt solution with access of oxygen, an electric current flows between the oxide scale as cathode and the metal exposed at the breaks as anode.

The strength of the current flowing must be largely determined by the rate of arrival of oxygen at the cathode, but the corrosion is concentrated on the iron exposed at the breaks in the scale. If the discontinuities are small, the attack may be intense; this combination of large cathode and small anode is one likely to cause pitting or trenching.

The presence of a thick oxide scale on metal is not needed for electrochemical corrosion. A strip of iron or zinc sheet partly immersed in a salt solution will suffer electrochemical attack. The portion nearest to the water line, where the replenishment of oxygen is easiest, will then be the cathode, while the anode, where attack proceeds, is a zone a little way farther down. In such cases, it has been possible to measure the electric currents (U. R. Evans and T. P. Hoar, 1932); the strength of current flowing is sufficient to account for the rate of corrosion actually observed. Five different methods are now available for the measurement of these local corrosion currents, and it is no longer necessary to regard the electrochemical mechanism of corrosion as a theory.

The equations governing the corrosion of a divalent metal, M, in presence of oxygen can most simply be written,

at the anode,  $M = M^{2+} + 2e$ ;

at the cathode,  $\frac{1}{2}O_2 + H_2O + 2e = 2OH^-$

If iron is corroding in salt water containing oxygen, the anodic product can be regarded as ferrous chloride, and the cathodic product as sodium hydroxide. Where they meet they will form ferrous hydroxide [ $FeO \cdot H_2O$  or  $Fe(OH)_2$ ], which will combine with further oxygen to give hydrated ferric oxide [ $Fe_2O_3 \cdot H_2O$  or  $FeO(OH)$ ], commonly known as yellow rust. If less oxygen is present, magnetite, in the black anhydrous form ( $Fe_3O_4$ ) or a green hydrated form, is usually produced.

These bodies, being thrown out of solution some distance from the corroding surface at points where the anodic and cathodic products meet, will not stifle further attack, so that rusting, when once started, usually proceeds readily (except in hard water where rust is produced in a clinging, protective form as explained below).

If oxygen is absent, and even to some extent if it is present, an alternative cathodic change is possible; namely,

The two types of cathodic reaction (oxygen reduction and hydrogen liberation) involve either production of  $OH^-$  or destruction of  $H^+$  ions, and thus render the liquid more alkaline or less acid.

The hydrogen-evolution type of attack occurs most readily in acid solutions, although certain metals, like zinc or aluminum, the oxides of which are soluble in alkali (forming complex anions), can liberate hydrogen from solutions of caustic alkali.

When an oxidizing agent is present, other cathodic reactions are possible, sometimes permitting the electrochemical corrosion to attain high velocity; in the attack of nitric acid on copper, the cathodic reduction of nitric acid constitutes an autocatalytic cycle, and the attack may become violent, especially in crevices where the corrosion products escape dispersal.

Very careful measurements of the corrosion of fully immersed iron and zinc have been carried out by G. D. Bengough (1927 *et seq.*), with J. M. Stuart, then A. R. Lee and later F. Wormwell; some of their experiments lasted several years. On horizontal zinc

or iron disks in stagnant potassium chloride solution, the corrosion rate was usually determined by the maximum rate at which oxygen could reach the specimen, which was itself influenced by the nature of the corrosion product; on iron the corrosion velocity often remained constant for long periods, suddenly changing when the physical character of the corrosion product underwent alteration.

Under conditions of shallow immersion, the corrosion velocity diminished when the depth of immersion was increased; in such cases, the oxygen was reaching the metal by diffusion. Beyond a certain depth of immersion, further increases in depth did not affect the velocity, since the oxygen was reaching the metal by convection.

**Corrosion by the Atmosphere.**—While the corrosion of fully immersed metal is frequently controlled by the rate of arrival of oxygen (water being everywhere in excess), the converse is true of atmospheric corrosion; here oxygen is everywhere in excess, and it is often the uptake of water which decides the velocity of corrosion. Vernon (1923 *et seq.*) and J. C. Hudson (1929 *et seq.*), who carried out much careful work on atmospheric attack, found that, in the case of metal exposed to indoor atmospheres, there is often a limiting humidity below which change is very slow. Thus, Vernon found that nickel exposed to air at a humidity below 70% undergoes little change; above this value, "fogging" takes place, unless the atmosphere is quite free from sulfur oxides. In the early stages, the deterioration is caused by a film made up of little droplets containing sulfuric acid (caused by the catalytic oxidation of adsorbed sulfur dioxide to give sulfuric acid, which then attracts more moisture); this is easily removed so that the brightness of the metal can be restored by simple wiping. On longer exposure, basic nickel sulfate is formed, and brightness can no longer be restored by wiping.

The corrosion of metals exposed out of doors increases with the sulfur oxides, largely derived from the combustion of coal, and is thus greater in towns or industrial regions than in the country. Near the sea, the presence of salt spray increases atmospheric corrosion. Careful measurements on numerous materials, ferrous and nonferrous, have been carried out by Hudson in various atmospheres. Iron and steel are corroded much more quickly than nonferrous materials. Among the materials included in Hudson's nonferrous tests, zinc, which corroded the fastest, usually suffered corrosion at four to five times the rate of 80/20 nickel-chromium alloy, which proved the most resistant among those studied.

**Corrosion Caused by an External Electromotive Force.**—While in natural corrosion there is usually a limit set to the rate of attack by the supply of some essential substance, no such limit exists where the metal undergoing corrosion is made the anode in an electrolytic cell supplied with current from an external source. In the absence of passivity (*see below*) or other complication, the rate of attack can be calculated, by Faraday's law, from the current forced through the cell.

Anodic action, however, does not always lead to attack. If a current be passed between two iron electrodes dipping into a liquid, two different changes may take place at the anode. The iron may pass into solution, giving a soluble ferrous salt, or, alternatively, hydroxyl ions may be discharged on the anode, leading to a protective oxide film; when once this film has been formed, the current flowing will be used in the evolution of oxygen gas. The decision between these two happenings depends largely on the pH value and the current density. At low values of pH and current density, the iron generally passes into solution as a soluble salt, whereas in weakly alkaline solution a protective film is formed, causing the metal to become "passive" so that corrosion ceases. In strongly alkaline solutions, some metals are attacked freely, forming complex anions. Thus, zinc can pass into solution as a zincate, while tungsten and molybdenum suffer anodic attack at high current efficiency, giving rise to tungstates and molybdates. With iron, dissolution in alkaline solutions occurs only at very high concentrations of alkali.

Even in acid solutions, an iron anode may become passive if the current density is sufficiently high, the establishment of passivity being favoured by stagnant conditions; under conditions

which repealed previous legislation, made no effort to control nominating primaries or conventions. It required the treasurer of every political committee with activities in two or more states to file periodic reports with the clerk of the U.S. house of representatives, four reporting dates being specified for nonelection years and six for election years. The sworn statements were required to show the name and address of each contributor of \$100 or more with the amount given, the total of other contributions, the names and addresses of all persons to whom expenditures of \$10 or more were paid, with the amount, date and purpose of each such expenditure, and the total of other expenses. Individuals spending \$50 or more in two or more states other than by a contribution were required to make a similar report of their expenditures. Each candidate for representative and for senator was required to file with the clerk and with the secretary of the senate, respectively, before and after each election, a sworn statement itemizing contributions and expenditures handled by him personally or by someone else with his knowledge and consent in support of his candidacy.

Under the act, as amended, any candidate for senator could spend up to \$10,000 and any candidate for representative up to \$2,500 unless state law prescribed a lower figure. Important categories of expenditures were excluded from the limits, and the limits themselves could be raised to a maximum of \$25,000 and \$5,000 respectively, under a formula that took account of the number of votes cast in the last election.

The act contained various other prohibitions, carrying forward one originally enacted in 1907 making it unlawful for any national bank or corporation organized under authority of congress to make a contribution in connection with any election, or for any corporation to contribute to federal campaigns.

**Hatch Acts.**—The Hatch act of 1939, amended in 1940, extended existing controls over federal civil-service employees by prohibiting all federal employees other than policy-making officers from taking active part in political campaigns. These limitations, as well as a ban on the solicitation of political contributions by one employee from another, applied to state and local officers employed in connection with activities financed in whole or in part by federal funds.

No political committee with activities in two or more states could legally receive or spend in excess of \$3,000,000 during a calendar year. It was also made illegal to contribute directly or indirectly an aggregate in excess of \$5,000 during a calendar year to or on behalf of any candidate for nomination or election to a federal office, or to a national political party or to an organization active on behalf of such a candidate, other than a state or local political committee. As the legislation was interpreted, individuals could give up to the limit to as many candidates or committees as they wished, and any number of different committees could spend up to the legal maximum.

The Hatch acts also contained prohibitions against buying goods, advertising or articles of any kind for the benefit of federal candidates, as well as provisions making it unlawful for anyone entering a contract with the United States government to make a contribution, measures that were largely unenforced.

**Labor-Management Relations Act of 1947.**—Trade unions, but not political committees formed under their auspices, were prohibited by this act from making contributions or expenditures in connection with the nomination or election of federal officials. The act also extended the prohibitions against corporate political action to include expenditures and nominations.

**England.**—Early measures in England culminated in the Corrupt and Illegal Practices Prevention act, 1883. This legislation, altered by several later enactments including the Representation of the People (Amendment) act, 1958, set the basic regulatory pattern. The expenses that might be incurred by a candidate for parliament during the campaign period were strictly limited according to the number of electors in each candidate's constituency (the authorized amounts averaging about £850 for each candidate in 1955, plus certain personal expenses up to £100 additional). The candidate himself, or a single election agent designated by him, was required personally to receive all money and to authorize

all expenditures. Detailed reports were required, showing the sources of funds and to whom expenditures were paid and for what purposes. Summaries of the reports appeared in local papers and were printed in a document prepared by the home office. The use of money for some purposes was prohibited (e.g., bribery, treating, precinct workers, music, banners, hired cars). Anonymously published campaign documents were forbidden.

Parliamentary candidates were permitted to mail one two-ounce letter free to each elector and to rent public buildings at maintenance cost. They could not buy radio or television time, though in fact each important party was provided limited amounts of free time during a campaign.

British efforts to regulate corrupt practices enjoyed general approval inside and outside the country, although the objectives sought were modest compared with those in some other places, especially the United States. No public accounting was required of money spent by central party organizations not directly allocable to an individual candidate, nor of money received and used on behalf of candidates outside the actual campaign period, usually about three weeks. No attempt was made to prevent campaign contributions and expenditures by corporations and labour unions.

The regulation of corrupt practices in local-government elections in England was similar to that of parliamentary elections; certain similar features were also adopted in other commonwealth nations.

**CORSAIR**, the name given by the Mediterranean peoples to the privateers of the Barbary coast who plundered the shipping of Christian nations. See **BARBARY PIRATES**.

**CORSE, JOHN MURRAY** (1835–1893), U.S. army officer and hero of the Civil War battle of Allatoona, was born in Pittsburgh, Pa., on April 27, 1835. He attended West Point and later studied law.

In 1861 he was appointed major in the 6th Iowa infantry. He distinguished himself in several campaigns, was wounded at the battle of Missionary Ridge (1863) and promoted to the rank of brigadier general. In command of a division during Sherman's Atlanta campaign, Corse played a leading role in one of the most dramatic events of the war. Hood in his campaign of harassment against Sherman's forces in Georgia in the fall of 1864, ordered an attack on a Union supply post at Allatoona, about 30 mi. N.W. of Atlanta. Corse, ordered to hold the post, moved in with a force of less than 2,000 and successfully repulsed an enemy numbering nearly 5,000. A third of the forces on each side were lost in the bloody battle and Corse was severely wounded. Philipp Bliss, the singing evangelist, wrote his popular hymn "Hold the Fort" in commemoration of the action.

Corse retired at the end of the war with the rank of major general. He became a collector of internal revenue and later a contractor. Active in Democratic politics, he was appointed postmaster of Boston in 1886. He died in Winchester, Mass., on April 27, 1893.

**CORSICA** (Fr. CORSE), an island in the Mediterranean sea, forms the sixth *département* of France by size (3,352 sq.mi.) together with 43 offshore islets. Corsica lies about 105 mi. from southern France and 51 mi. from Italy and is separated from Sardinia by the 7-mi. strait of Bonifacio. It has a north-south length of 114 mi. between latitude 41° 20' and 43° N. Ajaccio, the capital, is on the same latitude as Rome. Oval-shaped, the island has a maximum width of 52 mi.

**Physical Features.**—Corsica is the most mountainous island in the Mediterranean, with an average elevation of about 1,863 ft. Its highest summit, Mt. Cinto, reaches 8,891 ft. and there are about 40 other peaks rising above 6,500 ft.

Geologically Corsica represents two distinct mountain systems. The eastern and northeastern sector of the island consists of folded, alpine structures, most of them in metamorphosed schistses *lustrés*, and thought to be autochthonous nappes having their roots

in Tuscany, Italy. Heavily dissected, mountainous relief is characteristic, reaching 5,800 ft. in the district of Castagniccia (chestnut woods). North of the Golo river, the nappes are folded in wider, clearer amplitudes, the synclinal basins of Novella and St. Florent alternating with the two anticlinal ranges of the Agriates and Cap Corse. To the west and southwest of these alpine structures, the remaining two-thirds of Corsica comprise the rejuvenated remnant of an ancient land mass. This is granitic Corsica, with its rock types weathered into distinctive land forms. The hornblende granite weathers rapidly into softly rounded plateaus, while the hard granulites and rhyolites form the high ridges and rugged pinnacles notable in the Calanques de Piana on the west coast. Further variety is produced by gabbros, diorites, serpentines and eroded breccias of volcanic origin, while parallel and transverse dikes may run for several miles as scarped walls, especially in the southeast. Chemical weathering has been marked, especially in the curious hollowed-out *tuffoni* of the northwest, and in the low limestone karst (*q.v.*) of Bonifacio. Quaternary glaciation has only modified the high relief of the summits. Much more significant has been the deep valley erosion, the major valleys flowing first in flat-floored waterfalls (*e.g.*, Scala de Santa Regina).

A major contrast is presented between the coasts of the east and the west. In eastern Corsica the extensive coastal plain of Aleria (about 40 mi. in length and up to 8 mi. wide), together with smaller plains farther north and south, reveal emergent features with lagoons, sandspits, etc. Facing west, the coast has submergent features, with deep rias and small isolated plains at their head, cut off from each other by rocky headlands. Such are the drowned gulfs of Valinco, Ajaccio, Sagone and Porto, with former coast lines detached as in the Îles Sanguinaires and with deep water inshore. The ancient Hercynian folds and later fractures running northeast-southwest are represented by 30-40 main valleys and interfluvies on the western coast, making coastal communications difficult. In contrast the eastern mountain flanks are less broken and descend steeply and rapidly to the extensive coastal plain. This plain was infilled by the deposits of the two largest rivers, the Golo in the north and the Tavignano farther south, and by those of numerous secondary streams which flow down the eastern mountain sides. The upper courses of most of the rivers are flat-floored, high basins just below the mountain crests. From them the streams descend rapidly in their middle courses through gorges. The western rivers flow to the heads of the gulfs where they have formed small, isolated plains at the sea's edge, each one separated from that at the mouth of the next stream by cliffed promontories.

**Climate.**—The Corsican climate is typical of the western Mediterranean. By virtue of its insular position and moderate size, the temperature range is reduced and the precipitation is above the average. Mean monthly temperatures near the coast vary from about 50° F. in January to 75° F. in August. The annual precipitation ranges from about 24 in. at sea level to over 50 in. in the mountains. There is approximately the same amount on both sides of the island, thunderstorms having their maximum intensity on the eastward, leeward coast. On average there are 60-70 rain days in the year, the maximum occurring generally in the autumn, although the wet season is prolonged into the late spring. Summer drought is most pronounced in the extreme south. The snow line lies at about 4,500 ft. in April, but snow disappears from the peaks by late May. (J. M. Ho.)

**Vegetation and Animal Life.**—The flora belongs to the Sardo-Corsican province. The natural plant cover can be divided into four zones according to altitude. (1) The Mediterranean belt from sea level up to 1,300 ft., which includes halophytes (seacoast plants) with sandy habitat and rock creviced plant associations; *maquis*, with arbutus, tree heath, mastic, buckthorn, myrtle and rosemary; and *garigue* of *cistus*—the *maquis* and *garigue* alternating with olive tree cultivations and woods of cork oak or holm oak. (2) The submontane belt (1,300-3,000 ft.) consisting of woods of chestnut, pubescent oak (*Quercus pubescens*) or maritime pine (*Pinus pinaster*). (3) The montane belt (3,000-5,000 ft.) where are found pure or mixed communities of Corsican pine, beech and fir. (4) The alpine belt with Corsican alter shrub, stunted subshrub formations, grass communities and boulder vegetation in

altitudinal sequence. This zone extends to the bare areas of the higher summits.

The mountainous interior holds wild boar, foxes, deer and hares and also game birds. There, too, is the mouflon, the only European wild sheep. (R. E. G. P.-S.; MA. BU.)

**Archaeology.**—After a Neolithic period having affinities with that of North Africa and the eastern Mediterranean, which can be traced in the rock shelters by arrowheads and obsidian blades and scrapers as well as a traditional microlithic industry, the Chalcolithic culture penetrated to Corsica at the beginning of the 3rd millennium B.C. It did not use hypogea, but employed natural caves (rarely) for burials. Some rock paintings of this period in red ochre of a schematic art and possibly of Iberian treatment were discovered in shelters to the west of Cap Corse.

In the Early Bronze Age (2500-1700 B.C.) the important Megalithic religion covered the island with dolmens, great cists, and numerous isolated and grouped menhirs. Palaggio, situated 4 km. (2.4 mi.) from the sea and 2 km. to the right of the road from Sartène to the little port of Tizzano, alone comprises more than 90 menhirs in two rows. The granite of all these monuments was carefully worked. At the end of the Early Bronze Age, after the zenith of the Megalithic culture, occurred an insular phase of artistic evolution. This was represented first by engravings on dolmens (circles and bossed bulls' horns) and later by engravings on the menhirs, which progressively advanced to the stage of a true culture—that of the statue menhir—at the beginning of the Middle Bronze Age. More than 40 statues, varying from the archaic to sculpture in the round and from 6 to 9 ft. high, have been examined in the island's two principal groups; the southern group is the most dense and the most characteristic. The main centre of this culture, where it also reached its peak, was at Filitosa, a site 40 km. (25 mi.) S. of Ajaccio. There, between 1948 and 1959, 16 statues were found, most of them armed with swords and daggers in low relief. These statue menhirs are unique and their art form, peculiar to the island, cannot usefully be compared with that of groups elsewhere. The anthropomorphic statues of Corsica were probably representations of dead personages, for they were connected with a funerary cult. They have been dated from the 15th to the 14th centuries B.C., immediately before the arrival of a new civilization—that of the builders of circular, dry-stone monuments, sometimes of cyclopean arrangement, with inner chambers and passages. In the walls of one of these, six earlier statue menhirs were found broken up and used as building material.

These circular monuments, called *torre*, reach a diameter of about 50 ft. and have been definitely attributed to the period between the Middle and Late Bronze Age—1700 to 1200 B.C. They form part of a Mediterranean Bronze Age current covering, among other regions, Apulia in southern Italy with its *specchie* (rude stone structures); and Gallura and the north of Sardinia (*q.v.*) with its galleried nuraghi (dry-stone towers) or pseudonuraghi. These basically related monuments served both a funerary (by cremation) and a religious purpose; their importance lies in the fact that they were anterior to, or at the very beginning of, the Nuraghic civilization of Sardinia. In Corsica the principal circular monuments, of which there are about 30, are near Filitosa and, higher up, in the Taravo valley, at Balestra, at Foce and at Torre on the east coast near Porto-Vecchio. Of the Iron Age (Hallstatt) there are several funeral sites yielding ornaments and bronze weapons, tanged, as at Cagnano near Luri. In the centre of the island there are rock engravings with stylized and geometrical signs. (R. A. Gr.)

**History.**—The recorded history of Corsica (Greek *Cyros* or *Kyros*) begins c. 560 B.C., when Greeks from Phocaea in Asia Minor founded the town of Alalia on the east coast. Twenty years later almost the whole population of Phocaea, fleeing the Persian armies, joined the colony; but in 535 the Greeks were defeated in battle by an allied Carthaginian-Etruscan fleet. Although Herodotus states that they abandoned Alalia, archaeology shows that Greek influence remained paramount there during the next 300 years, in spite of Carthaginian and Roman ambitions. Sicilian Greeks raided the coast in 453 and 384, but the island had fallen

under Carthaginian domination by the end of the 4th century. In 259 B.C. Lucius Cornelius Scipio won a great victory over the Carthaginians and captured Alalia, then known as Aleria.

*The Romans.*—The indigenous population put up a ferocious resistance to the Roman invaders. The conquest of the island was achieved in a sequence of hard-fought campaigns between 234 and 163 B.C. Corsica, with Sardinia, was formed into a single Roman province. In 93 B.C. Gaius Marius founded Mariana; 13 years later Lucius Cornelius Sulla rebuilt Aleria.

Though the philosopher Lucius Annaeus Seneca complained bitterly of his exile in Corsica (A.D. 43–49), under the Roman empire the island flourished. Ptolemy's map shows a string of ports round the coasts and numerous inland settlements. The Romans built roads, cultivated the fertile east coast and implanted their language—the basis of the subsisting Corsican dialect. Christianity had taken root by the 3rd century.

*Barbarian Invasions and the Papacy.*—With the collapse of the West Roman empire the Vandals invaded Corsica (c. 450), entirely destroying Aleria. They are remembered chiefly for deforesting large areas for shipbuilding timber. A brief Ostrogothic occupation intervened before the island was finally reconquered by the Byzantines and organized with Sardinia as a province (552). The Corsicans gained nothing by the change, for they were mercilessly overtaxed by corrupt officials.

In 725 Corsica was annexed to the Lombard kingdom of Italy, to be freed about 50 years later. Meanwhile the Frankish king, Pepin the Short, in 757, had promised the island, when liberated, to the papacy. The donation was confirmed by Charlemagne. The pope was thenceforth titular ruler of Corsica, but in practice delegated its administration.

Before the Corsicans could benefit by this arrangement they were subjected to about 300 years of Saracen invasions. Raids from north Africa had begun early in the 8th century; incursions from Spain followed. In spite of expeditions organized by Charlemagne and his son Pepin of Italy the attacks became increasingly frequent and destructive. The Tuscan count Boniface II founded Bonifacio, in the south, after a victorious crusade (c. 828); but by the mid-9th century conditions had become so desperate as to produce a mass exodus of Corsicans to Rome. Corsica, it seems, was finally freed from the Saracen menace early in the 11th century by the combined action of Pisan and Genoese fleets.

*Pisa and Genoa.*—In 1077 Gregory VII asserted papal authority by entrusting the administration of Corsica to the bishop of Pisa. The domination of the Pisans was an enlightened ecclesiastical protectorate; innumerable churches were built under their direction. Genoa, however, soon manifested hostility. In 1133 Pope Innocent II attempted to appease the conflict by dividing the jurisdiction of the six Corsican bishoprics between the republics of Pisa and Genoa, three to each. The compromise satisfied neither; war

between them was constant off the coasts. Bonifacio, fiercely disputed, fell to the Genoese in 1187; peopled by their citizens it became their base for territorial expansion.

The 13th century saw the rise to power of the ambitious feudal family of Cinarca. During the next 250 years its leaders, established in large fiefs in the west and south, sought to extend their domination over the whole island. Thus Sinucello della Rocca, known as the *giudice* (judge) of Cinarca, virtually ruled Corsica during the latter half of the 13th century, until, as a vassal of Pisa, he was captured and imprisoned by the Genoese. Meanwhile Genoa had defeated the Pisans in the naval battle of Meloria (1284), and the role of Pisa in Corsica was at an end.

*Genoa and Aragon.*—In 1296 Pope Boniface VIII invested James, king of Aragon, with the suzerainty of Corsica and Sardinia. This unfortunate step inaugurated a new period of rivalry and war. While Aragon sought to prepare the annexation of the island by alliances with the nobles of Cinarca, republican Genoa cultivated the allegiance of the common people, who had begun to resent the increasing pretensions of the minor feudal lords. An Aragonese attack on Bonifacio in 1346 drove the Genoese to action. In the following year they sent an expeditionary force to conquer the island, but the Black Death cut short the campaign. It was not until ten years later that they could again turn their attention to Corsica. The moment was favourable. Sambucuccio d'Alando, elected leader of the populations of central Corsica, led a successful revolt against the feudal lords of that region. Needing support, he appealed to Genoa to assume the government of the island. The Genoese seized the offer with alacrity. Their governors' authority, however, was only operative in the north and centre, where the feudal regime had been broken: this territory was known as the Terra di Comune. The Cinarchesi, favouring Aragon, remained in control of the south.

Arrigo della Rocca was the first who attempted to dominate Corsica with Aragonese aid (1376). Genoa, alarmed at the prospect of a costly war, assigned Corsica to a financial company known as the Maona. Its forces had to combat Arrigo on and off until his death in 1401. Bastia, founded by the Genoese about 1380, became their administrative capital. With the death of Arrigo, his nephew, Vincentello d'Istria, took up the Aragonese cause. By 1420 he had all but ousted the Genoese from Corsica. Aragonese troops, commanded by King Alfonso V, landed the same year. The town of Calvi submitted; but the Genoese inhabitants of Bonifacio successfully resisted the Spanish fleet in a heroic five months' siege. Alfonso V thereupon abandoned the island, leaving Vincentello as viceroy. Vincentello's rule was uncontested until he was captured and executed by the Genoese in 1434.

At this period a new class of Corsican leaders emerged: the *caporali*. Originally elected magistrates or chiefs of the districts freed from the feudal regime, they came to form an influential and greedy subaristocracy, obtaining pensions from the Genoese and other rulers in return for their co-operation.

*Bank of San Giorgio.*—After a period of anarchy the Genoese in 1453, at the request of a Corsican delegation, placed the island under the government of the Bank of San Giorgio. This was a powerful financial company already entrusted with the administration of Genoa's eastern colonies. The rule of the bank was opposed by a series of formidable revolts led by the war lords of Cinarca: Raffe da Leca (executed in 1456), Rinuccio da Leca (executed in 1489), Gian Paolo da Leca (exiled in 1500) and Rinuccio della Rocca (assassinated in 1511). The officers of the bank retaliated with the utmost ruthlessness: they burnt villages, crops and trees and forcibly exiled the population of the Nioio (a mountain region). With the death of Rinuccio della Rocca, who had kept them at war for ten years, the power of the Cinarchesi was finally broken.

The Genoese scorched earth policy was compensated by various efficient constructive works: the coastal towns were refortified, Ajaccio was founded (1492), and a chain of watchtowers built round the coasts as defense against Moorish raids. The administration was not, in its form, tyrannical. The governor was assisted by three lieutenants and a *vicario*, who judged criminal cases; local government and civil jurisdiction remained in the hands of

PAUL ALMASY

BONIFACIO, ON THE CLIFFS OF CORSICA; FOUNDED IN 828

the Corsicans, the *pievi* (groups of parishes) being administered by a podesta (mayor) aided by *raxioneri* (accountants), all Corsicans and elected by the people. Nonetheless many of the more dynamic Corsicans preferred to emigrate rather than submit to the unpopular foreign regime. Constant raids on the coasts by Barbary pirates added to the general distress. As soldiers of fortune Corsicans made their names in all the Italian states; others built up fortunes in Spain and Marseilles.

**Sampiero Corso and the First French Intervention.**—It was a soldier of fortune of humble origin, Sampiero Corso, who once again offered the Corsicans an alternative to Genoese rule. Engaged first in the troops of Giovanni de' Medici and then in the French army with the rank of colonel, in 1553 Sampiero prevailed on Henry II of France (then at war with the Holy Roman emperor Charles V, ally of Genoa) to invade Corsica. The French army was supported by the Turkish fleet and a strong Corsican contingent commanded by Sampiero. By 1556, when the truce of Vauclles put an end to hostilities, the French had occupied the whole island except Calvi and Bastia. They ruled judiciously until Corsica was returned to Genoa by the treaty of Cateau Cambrésis (1559), to the disappointment of most of the people. Having unsuccessfully solicited aid from Turkey, Sampiero returned to Corsica with a handful of followers and waged a desperate three years' war against the Genoese until he was killed in an ambush in 1567.

**Genoese Rule.**—The republic, having assumed direct control of the island, reorganized its administration. A revised legal code was promulgated. Justice was rendered by the governor, by various officials (some of whom were Corsicans) and by the podestai. The governor could condemn to death without trial. Eighteen Corsican delegates—12 for the northeast (the *nobili dodici*) and 6 for the southwest (the *nobili sei*)—were charged to formulate the grievances of the people. Every year they sent an *oratore* to Genoa to present their requests. If this regime was not really totalitarian, its execution left much to be desired. The Genoese officials were usually ruined gentlemen who sought to recuperate their fortunes by selling privileges and favours. The administration of justice was notoriously corrupt. In these circumstances the Corsicans preferred private vengeance; the vendetta (*q.v.*), a custom dating back to the early middle ages, increased, in spite of the harsh repressive measures of the Genoese. In 1676 Genoa ceded a tract of land to about 700 Mainote Greeks, refugees from Turkish oppression. They remained loyal to the republic.

**Nationalist Rebellions.**—In 1729 rebellion broke out in central Corsica following a dispute with a Genoese tax collector. Genoa solicited help from the Holy Roman emperor Charles VI, who sent troops and negotiated a peace in 1732. Its terms, however, were not respected, and in 1734 the Corsican nationalists again took to arms. The leaders, Luigi Giafferri and Giacinto Paoli, declared the island independent and proclaimed a democratic constitution.

In 1736 the German adventurer Theodor, baron von Neuhof (*q.v.*) landed with a shipload of arms and supplies. Promising important foreign help, he managed to persuade the Corsican leaders to crown him king (Theodore I) at Cervione. This fanciful but not incompetent charlatan distributed titles of nobility, coined money and won some military successes until, running out of funds, he left the island the same year. The rebellion nonetheless continued. Genoa sought assistance from France. The comte de Boissieux (Louis de Frétat) was defeated by the Corsican patriots in 1738; but the marquis de Maillebois (J. B. Desmarests), replacing him, overcame resistance in a rapid campaign which drove Giafferri and Paoli into exile. Peace was re-established when the French withdrew in 1741.

Two years later Theodore reappeared on a British ship, but left hurriedly, having been coldly received by his "subjects." The Corsicans obtained more serious aid from Charles Emmanuel III, duke of Savoy-Sardinia, then the ally of the Austrians and the British in the War of the Austrian Succession. British warships and Sardinian troops captured Bastia in 1745, but the town was retaken soon afterward by a combined Genoese-Franco-Spanish force.

Unable to master the situation, Genoa again obtained French help. The marquis de Cursay (Séraphin Rioult de Douilly) in the

years 1749–52 conciliated the patriots and made himself so well respected on the island that the Genoese, jealous of his influence, contrived to have him removed. Thereupon the Corsican leader Giovan Pietro Gaffori put into execution a previously prepared democratic constitution. He was murdered in 1753.

**Pasquale Paoli.**—At this crucial moment in the national struggle Pasquale Paoli (*q.v.*), the 30-year-old son of the exiled Giacinto, landed in Corsica. In July 1755 he was elected general of the Corsicans at an assembly in the Franciscan monastery of San Antonio della Casabianca. Within the next six months he had overcome a rival Corsican faction. With the Genoese confined to their coastal towns, Paoli proceeded to organize Corsica as an independent democratic state from his mountain capital, Corte. The constitution that he gave to his countrymen was more liberal than any known in his day. The legislative power was exercised by *consulte* composed of representatives elected by all male Corsicans of 25 or more years of age; Paoli himself held the executive power assisted by an elected council. During the 14 years of his rule this man of genius was able to lead the Corsicans in a great regenerative effort: he repressed the vendetta, created a university and a printing press, coined money, founded a port (L'Île-Rousse) to replace Genoese Calvi and built a navy which took part in his conquest of the island of Capraia (1767).

The Genoese, powerless, once again turned to France. By the treaty of Compiègne (1764) Louis XV undertook to garrison their coastal towns in Corsica for four years. Paoli vainly sought an alliance with France in which Corsican independence would be recognized. In 1768 the Genoese sold their rights on Corsica to France, and French troops invaded the island in overwhelming numbers. The Corsicans were decisively defeated at Ponte Nuovo in May 1769. Paoli embarked for England in June. Two months later, on Aug. 15, Napoleon Bonaparte was born in Ajaccio.

**The French Revolution and the Napoleonic Period.**—For the next 20 years Corsica was administered as a *pays d'états* under the French monarchy, which recognized the Corsican nobility and accomplished various useful public works. But the French Revolution (1789) was welcomed by the Corsicans. In 1790 the constituent assembly declared Corsica a *département* of France. By virtue of the amnesty of political exiles Pasquale Paoli returned to the island the same year. Enthusiastically acclaimed by the people, he was appointed president of the administrative council and commander-in-chief of the national guard. Paoli, however, had little sympathy with the new regime. He was opposed to the extremes of revolutionary policy and resented the influence of the Jacobin clubs in the Corsican towns. Blamed for the failure of an expedition against Sardinia in 1792, he was arraigned by the Convention (April 2, 1793). His response was to convoke a national assembly at Corte in May 1793, an act tantamount to a declaration of rebellion. Napoleon Bonaparte, loyal to revolutionary France, was driven off the island by Paoli's partisans. Paoli appealed for British protection.

Admiral Samuel Hood reached Corsica in Feb. 1794; by August the British had reduced the three coastal towns held by revolutionary troops. In June the Corsican assembly formally accepted the constitution of the Anglo-Corsican kingdom. British rule lasted two years, with Sir Gilbert Elliot as viceroy. Paoli's presence being considered responsible for growing unrest, he was invited in 1795 to return to England, where he died in 1807.

In Aug. 1796 the British government ordered the evacuation of Corsica. An expeditionary force, dispatched by Napoleon from Italy, moved into the island in October while British troops were embarking. British forces again occupied Bastia for a short time in 1814, but in the settlement of 1815 Corsica was restored to the French crown.

**19th and 20th Centuries.**—During the 19th century the French accomplished the immense task of building roads in Corsica and providing public education. The island remained underdeveloped but the Corsicans found many opportunities for making successful careers in continental France and the French colonies. With the final suppression of banditry, in the 1930s, and the elimination of malaria at the end of World War II, Corsica—*l'Île de Beauté*—

began to attract an important tourist traffic.

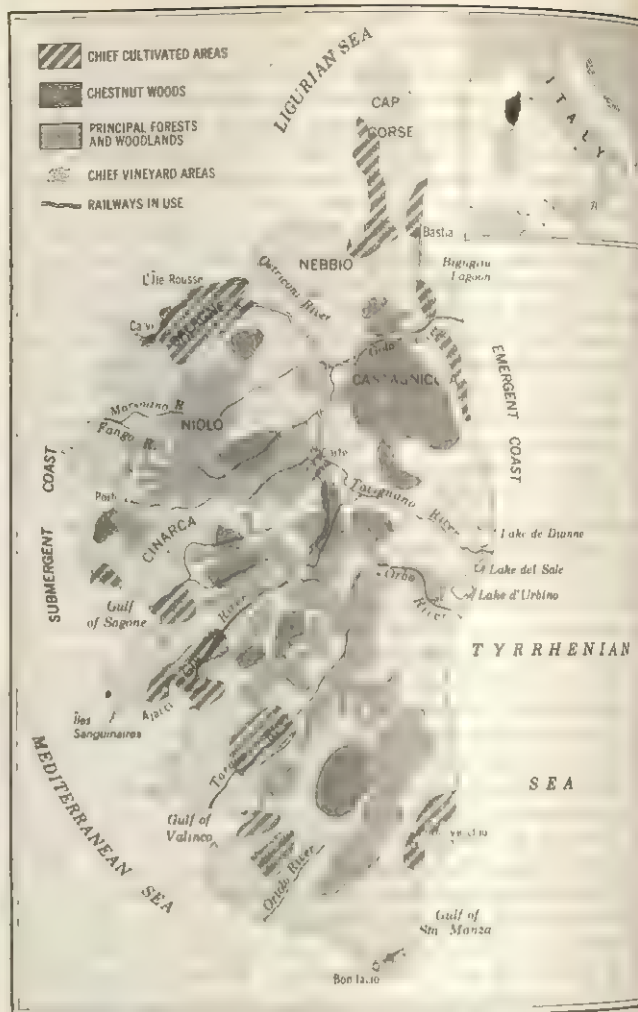

Napoleon secured the permanent loyalty of his countrymen to France. More than 20,000 Corsicans died in World War I. Mussolini's claim that Corsica formed a natural part of Italy met with no response from the Corsicans, as became obvious when in Nov. 1942, during World War II, 80,000 Italian troops under Gen. G. Magli occupied the island. Later they were joined by about 15,000 Germans. The Corsicans organized a redoubtable resistance (incorporated in the Front National) which, when Italy capitulated on Sept. 8, 1943, was able to liberate Ajaccio and inflict serious damage on the German forces, the Italians co-operating or remaining neutral. Free French units from Algiers joined the struggle on Sept. 20. Between Sept. 29 and Oct. 4 the Germans were driven from the island, retreating via Bastia. The Italians retired to Sardinia. As the first liberated *département* of metropolitan France Corsica served as a valuable base for the Allies.

The *coup d'état* of May 13, 1958, in Algiers (see FRANCE: History) was followed on May 24-25 by a similar movement in Corsica, where committees of public safety were set up in Ajaccio, Corte, Calvi and, subsequently, Bastia and Bonifacio. Corsica thus played a prominent part in the events which brought Gen. Charles de Gaulle to power as the first president of the 5th French republic. (D. CA.)

**Population.**—In 1954 the population of Corsica was 246,995. Nearly three-quarters lived in settlements of less than 2,000 inhabitants. The distribution of chestnut forests, formerly an important source of food, helps to explain the marked concentration of many villages and hamlets at 1,300 to 2,500 ft. above sea level (114 out of 204 settlements in northeast Corsica) and for the traditional high density of population in the district of Castagniccia. Favoured areas, such as the semiurban environs of Bastia, Ajaccio (*qq.v.*) and L'île-Rousse, and the fertile districts of Cap Corse and the Balagne, have the highest densities, with more than 500 persons per square mile. Nearly one-half of the country has an average density of from 50 to 150 per square mile, and almost as large an area is very sparsely settled. The uplands of Agriates and the central mountain chain are almost deserted. The scourge of malaria along the coasts below 1,000 ft. (*i.e.*, the upper limit of the mosquito *Anopheles maculipennis*), especially in the eastern plains, explains their low densities. After a number of half-hearted efforts a vigorous campaign in 1948-49 made the plains healthy for the first time in centuries. Despite a high birth rate the population only grew from 163,896 in 1801 to 322,854 in 1936. Since then it has fallen rapidly and by 1961 was estimated at around 140,000. Emigration, the result of rural poverty and the lack of industrial employment, has long been a feature, accelerated further during World War II by refugee movements from the island. There were many Corsican casualties in the war.

In 1954, 84% of the urban and 29% of the total population lived in the two principal towns, Bastia (42,729), the chief port, and Ajaccio (28,732), the administrative capital. Apart from the cities, six other centres have today between 2,000 and 5,000 inhabitants, all on the coast except Corte (*q.v.*), the third town (4,369) and for a short time in the 18th century the capital. Bastia owes its importance to its favourable position as the nearest port to southern France, its control of much of the trade of the east coast, the terminus of the railway system and its being the outlet for the most densely populated hinterland. Ajaccio is well placed to dominate the commercial activities and tourism of the west coast.

The physical characteristics of the people are strikingly uniform and perhaps of ancient ethnic identity. In the past the strict system of marriage within a group of related families may have aided this; certainly the vendetta between opposing families was a negative control. The Corsicans are Roman Catholics, apart from a small minority of Greek Orthodox at Cargèse, descended from Greek settlers in the 18th century. The Corsican dialect, is more akin to Italian than French, and is widely spoken. A northern variety, Cismontan, is of Tuscan origin, and in the south Oltremontan has more affinities with the dialect spoken in northern Sardinia.

J. M. HOUSTON

PRINCIPAL TOWNS AND CITIES, RAILWAYS AND LAND USE IN CORSICA

**The Economy.**—Hampered by lack of capital and primitive methods of agriculture, the cultivated land has never been of much importance. Cereal lands declined seriously after the mid-19th century; early vegetables now occupy a more extensive area and have a more promising future. Olive groves, especially in the Balagne, and vineyards in Cap Corse and the main valleys have been traditionally the chief crops. Fruit trees, especially citrus, almonds and peaches are cultivated in the low, sheltered areas of Nebbio, Balagne, Porto-Vecchio and Ajaccio. Chestnuts, once a dominant source of food supply, have greatly declined except in the Castagniccia. Most cultivators are proprietors of holdings averaging about 44 ac. The land is much fragmented and terracing on the mountain slopes is extensive. A typical holding may have a small vineyard and olive grove, valley land periodically reclaimed from waste or under intensive cultivation, and a share in the communal chestnut woods and pastures.

Rough pasture, still utilized seasonally by transhumant flocks of sheep and goats, occupies more than a quarter of the total area. A large number of dairies produce *broccio* from the goats' milk, which is sent to Roquefort, France, for final processing as cheese. Two-thirds of the ewes' milk is also made into cheese.

Fishing has never been important and is still largely a subsistence economy. The industries of Corsica are of small scale and diverse, being chiefly dependent upon the agricultural and forest products. They include the preparation of tannic acid from chestnut bark; the manufacture of edible pastes, cheese, tobacco and citron preserves; making semfinished pipes from the roots of heath; canning fish; sawmilling; and charcoal making. There is also the bottling of mineral waters from local spas (notably Orezza), the mining of anthracite and several nonferrous metals, and the quarrying of granite, marble and amianthus, a kind of

asbestos which is found and processed at Canari. After 1937 some hydroelectric plants were installed, but there has been little capital available to exploit fully the potential power of the rivers.

Corsica is well served by regular shipping services from the ports of Marseilles, Toulon, Nice, Genoa and Leghorn, and also by air transport; but internal communications are rather poor. A survey of 1949 showed that about half the main roads were too narrow, and there are still villages inaccessible by road. A motor road of varying quality encircles the island to link the coastal towns. A narrow-gauge railway connects Bastia and Ajaccio with a branch line to L'Île-Rousse and Calvi. The eastern branch line to Porto-Vecchio was left unrepaired after destruction during World War II.

**CORSICANA**, a city of central Texas, U.S., seat of Navarro county, is about 55 mi. S.S.E. of Dallas. Named by Jose Antonio Navarro after Corsica, where his father was born, it was settled in 1848, incorporated in 1850 and chartered in 1871. (For comparative population figures see table in TEXAS: Population.)

Site of an early oil discovery (1894; first production 1895), the area's petroleum output is valued at \$10,000,000 annually. Navarro county is a large cotton producer and is noted for its fine Hereford cattle.

(N. McG.)

**CORSINI**, a Florentine princely family, whose first recorded ancestors rose to wealth as wool merchants in the 13th century. As typical members of the *popolo grasso* (rich merchants) which ruled Florence during the later middle ages, they regularly served as priors and ambassadors of the commune. Filippo Corsini (1334–1421) was created count palatine by the emperor Charles IV in 1371. Two Corsinis were bishops of Fiesole, Andrea (1349) and Neri (1374); and two bishops of Florence, Piero (1363) and Amerigo (1411). Though some of the Corsini opposed the Medici, the family as a whole continued to flourish in business and politics under Medici rule, acquiring titles, lands and offices. Thus another Filippo (1578–1636), who managed affairs in Rome, was created by Pope Urban VIII marquis of Sismano, Casigliano and Civitella, of which his father Bartolomeo (1545–1613) had earlier purchased the lordships; and Bartolomeo di Filippo (1622–85) was in turn made marquis of Laiatico and Orciatice by grand duke Ferdinand II, and marquis of Giovagallo and Tresana by the king of Spain. Further titles followed the election of Lorenzo Corsini as pope Clement XII in 1730; his nephew Bartolomeo (1683–1752) was made prince of Sismano and a grandee of Spain (1732). Lorenzo began the Biblioteca Corsiniana, now in the Accademia dei Lincei at Rome. Throughout the Napoleonic period and down to the unification of Italy the Corsini remained active and influential in Tuscan affairs. The family continues.

**CORTE**, the largest inland town in the island of Corsica, France, is situated on the Tavignano river 84 km. (52 mi.) N.E. of Ajaccio by railway. Pop. (1962) 5,268. At the upper (west) end of the town stands the citadel built in 1420 by H. Vincetello d'Istria, the Aragonese viceroy, and to the southwest are the crags of Monte Rotondo. Corte was the island's capital under the provisional government formed by Pasquale Paoli (q.v.) during his dictatorship of 1755–69, and during the English occupation under Sir Gilbert Elliot (1794–96). The only buildings of interest are in the upper town and include, opposite the church, the Maison Gaffori, the scene in 1750 of the heroic resistance to the Genoese made by Mme. Gaffori, who held the house until relieved by her husband, Gen. Giampietro Gaffori. Both the general and Paoli are commemorated by statues. There are marble quarries in the neighbourhood and the town has a trade in wine, olive oil, chestnuts and cheeses.

**CÔRTE-REAL, JERÓNIMO** (1533–1588), Portuguese epic poet who endeavoured, with little success, to follow in the path opened by Camões' *Lusíadas*, was of the same noble family as the famous explorer Gaspar Côte-Real. He took part in military actions on land and at sea. He had some gift for painting as well as being a poet and soldier; one of his pictures is preserved in the church of S. Antão in Évora. He produced three epic poems: *Sucesso do segundo cerco de Dio* (1574), on the historic siege of that Indian island-fortress; the *Austriada* (1578), in Spanish, on the victory of Don John of Austria at Lepanto; *O Naufrágio de Sepúlveda* (1594). All are long, discursive and prosaic and are of only slight literary value.

(N. J. L.)

**CORTÉS, HERNÁN** or **HERNANDO** (1485–1547), Spanish conqueror of Mexico, born at Medellín, Estremadura, in 1485. He studied law at the University of Salamanca but returned home in 1501, probably without a degree. In 1504 he sailed to Santo Domingo (Hispaniola), where he settled as a farmer and public notary in Azúa, a small town on the island, while friends and neighbours sailed for dangerous if glorious conquests. In 1511 he accompanied Diego Velázquez in his expedition to Cuba, where he became alcalde of Santiago (then the capital). Velázquez sent Cortés to Yucatán to rescue two unsuccessful expeditions and to explore the country. On Feb. 19, 1519, Cortés set out with 11 vessels, 508 soldiers and captains, 100 seamen including pilots and masters, 16 horses, 10 bronze guns, 4 falconets and 13 shotguns. In March 1519, he landed at Tabasco where he stayed for a time in order to gain knowledge from the natives, who, though somewhat awed by the strangeness of the men, the weapons and the animals, fought and defended their land. He won them over however and received presents from them, as well as 20 women, one of whom, Doña Marina (Malintzin), became his mistress and interpreter and bore him a son, Martín. He sailed to another spot on the coast and founded Veracruz, mainly to have himself elected captain general and chief justice by his soldiers as citizens, thus shaking off the authority of Velázquez. He then had his ships run aground and dismantled, a fact which gave rise to the legend that he burned them. He set out for the interior, relying sometimes on force, sometimes on amity toward the local chiefs but always careful to reduce disturbance and duress to a strict minimum. The nation of Tlaxcala, in a state of chronic war with Montezuma, ruler of the Aztec empire of Mexico, resisted Cortés at first but when defeated became his most faithful ally. Rejecting all of Montezuma's threats and blandishments to keep him away from Tenochtitlán or Mexico, the capital (rebuilt as Mexico City after 1521), Cortés entered the city on Nov. 8, 1519, with his small force and only 1,000 Tlaxcaltecs. Montezuma, believing him to incarnate the Aztec god Quetzalcoatl, received him with great honour. Bernal Díaz, a soldier in the army, gives a vivid picture of the wealth of the city, the horrors of its human sacrifices and the magnificence of the emperor. Cortés decided to seize Montezuma in order to hold the country through its monarch, and achieve not only its political conquest but its religious conversion. He found a convenient pretext as the news reached the city that the garrison he had left in Veracruz had been attacked by the Indians and his chief killed. He went with his officers to the palace and seized Montezuma whom he put in irons. He obtained the surrender of the leader of the Veracruz attack and burned him at the stake using for faggots the wooden weapons he discovered Montezuma had amassed. This done, with his own hands he unlocked the irons on the emperor's feet. He was by that time master of Mexico. But then Montezuma first, and Cortés later, heard of the arrival of a Spanish force under Pánfilo de Narváez sent by Velázquez to deprive him of his command. Leaving a garrison in Tenochtitlán of 80 Spaniards and a few hundred Tlaxcaltecs, he marched against Narváez, defeated him and enlisted his army in his own forces. On his return, he found the Spanish garrison after an irresponsible aggression besieged by Indians. Montezuma was killed as he was trying to induce the Indians to cease their

attacks. Hard pressed and lacking food, Cortés decided to leave the city by night. The operation was performed, but with heavy loss in blood and booty. After six days of retreat he won the battle of Otumba over the Indians sent in pursuit (July 7, 1520). Well received by his allies of Tlaxcala, he reorganized his forces, subdued the neighbouring territories and after a stubborn siege captured the city (Aug. 13, 1521). This victory marked the fall of the Aztec empire.

Several embassies he had sent to Spain convinced the emperor Charles V of the immense value of the conquest. Cortés returned to Spain (1528), was appointed captain general and made marqués del Valle de Oaxaca. He lived like a prince and worked like a statesman. He revealed himself as the greatest of the conquerors, intent on organizing the land, studying its resources and pushing forward the work of exploration within and outside the country he had conquered. His enemies in Madrid and in Mexico did their best to thwart his efforts. His goods were seized by order of the council of the Indies and his retainers imprisoned. He went to Spain to appeal to the emperor, who received him with marks of honour and friendship; but he returned to Mexico with a diminished authority, for Charles V appointed Antonio de Mendoza as viceroy. Frustrated in his ambition as governor of the country he had conquered, Cortés explored the peninsula of Lower California (1535) and surveyed part of the gulf between it and Mexico. Earlier, his exploration of Las Hibueras (Honduras) was a feat of leadership and endurance perhaps even greater than his conquest of Mexico.

Discouraged by his struggle with unworthy adversaries, Cortés sailed to Spain again. This time he was received coldly. He attended the emperor assiduously and served as volunteer in the disastrous expedition against the pirates of Algiers in 1541. Kept at arm's length by the noblemen who surrounded Charles V, he was unable to take a military part worthy of his talents in that enterprise which under his command would in all likelihood have been a brilliant success. The emperor was unable to find employment for the ablest leader in the country. He retired from court and died in his estate of Castilleja de la Cuesta near Seville on Dec. 2, 1547. (See also MEXICO CITY; AZTEC.)

The only writings of Cortés are the five letters addressed to Charles V. The best edition is that of Francisco Antonio Lorenzana, archbishop of Mexico, entitled *Historia de Nueva España escrita por su esclarecido conquistador, Hernán Cortés, aumentada con otros documentos y notas* (1770). An English translation, edited by Francis A. MacNutt, was published in 1908.

See also references under "Cortés, Hernán" in the Index volume.

**BIBLIOGRAPHY.**—The conquests of Cortés have been described by Antonio de Solís in *Historia de la conquista de México* (1685, 2nd ed. 1790), and by Bernal Díaz del Castillo in *Historia verdadera de la conquista de la Nueva España* (1632), English trans. by A. P. Maudslay, "Broadway Travellers Series" (1928). See also F. A. MacNutt, *Fernando Cortés and the Conquest of Mexico 1485-1547*, "Heroes of the Nations Series" (1909); H. D. Sedgwick, *Cortés the Conqueror* (1926); Francisco Cervantes de Salazar, *Crónica de la Nueva España* (1924); Salvador de Madariaga, *Hernán Cortés, Conqueror of Mexico*, 2nd ed. (1955); M. Collis, *Cortés and Montezuma* (1955).

(S. DE M.)

**CORTÉS**, a small department of Honduras facing the Caribbean sea. Pop. (1961) 199,215; area 1,527 sq.mi. The department consists mostly of coastal plains and river lowlands, has fertile soils and an annual precipitation of 60 to 80 in. It has good transport facilities. Main products are bananas for export with nearly 40% of the national total. It also produces rice, sugar, sweet potatoes, poultry and cattle. Puerto Cortés (pop. 12,228) at the mouth of the Ulúa river is the largest port in Honduras and is connected by Inter-Ocean highway with Tegucigalpa. The departmental capital, San Pedro Sula (*q.v.*), is an important banana and sugar centre.

(C. F. J.)

**CORTES**, the plural form of a Spanish word meaning court, is used in particular to designate the parliaments of the medieval Spanish kingdoms and, in modern times, the national legislative or deliberative assembly. The *Cortes* developed in the middle ages when elected representatives of the free municipalities began, as of right, to take part in the deliberations of the *curia regis* on

certain subjects. Their admission was due to the crown's need for financial aid beyond that provided by its customary dues and its inability, in law, to impose extra taxation without the consent of the municipalities. In both León and Castile the *Cortes* were in existence by the early 13th century. Their functions and procedures were similar and, after the union of the two crowns (1230), they often held joint meetings—a procedure which was normal after 1301. Parliaments also functioned in Catalonia from 1218, Valencia (1283), Aragon (1274) and Navarre (1300).

The *Cortes* of León and Castile was composed of three estates: nobles, clergy and the *procuradores* of the free municipalities (*concejos*), who bore written instructions (*poderes*) from their electors. Redress followed supply. The king convoked meetings when and where he pleased. The crown's proposals were discussed and voted on by the whole *Cortes*. The three estates also had the right to present petitions to which the king must reply. If he accepted a petition it became law. During the 14th century the *procuradores* dominated the *Cortes* because they, and only they, could authorize the special taxation needed by the crown. The nobles, largely exempt from such taxation, and the clergy virtually withdrew from the *Cortes* and an alliance of king and *procuradores* was used to weaken the political power of the magnates. The influence of the third estate in the Castilian *Cortes* reached its peak in the last decades of the 14th century, because of the continuous needs of the early Trastámara kings to finance their wars. Under John I, the *procuradores* not only intervened in foreign affairs and administrative matters outside their earlier competence, but insisted on supervising the royal accounts and on the formation of a royal council on which they were represented. Decline, thereafter, was swift. Alienation of crown lands reduced drastically the number of free municipalities entitled to be represented. Roman and canon lawyers, dependent on the king and partisans of royal supremacy, secured a foothold in the *Cortes*. The crown then contrived, by various devices, to lessen its financial dependence on the *procuradores* and their capacity to resist its demands. Nevertheless, and despite its part in the rising of the *comuneros* against the emperor Charles V (1520-21), the *Cortes* of Castile was more prominent in 16th-century affairs than has often been thought.

The Catalan *Cort general* had three estates, which, in theory, the sovereign was obliged to summon at regular intervals. Barcelona sent five representatives (*sindichs*), the other municipalities only one. Redress preceded supply, and the *Cort* had legislative power. Royal proposals were studied separately, in committee, by each estate and these informed each other of their conclusions before meeting in plenary session under the presidency of the crown. From the mid-14th century a permanent parliamentary commission (*diputació del general*), resident in Barcelona, was set up to act when the *Cort* was not in session. In practice the Catalan parliament was strongly oligarchical. The parliament of Valencia was modeled on that of Catalonia, and the Aragonese *Cortes* borrowed from the Catalans the idea of a permanent commission, the form of municipal representation, and other features. In Aragon, however, the magnates and lesser nobility were separately represented, and the nobles were always very powerful. A special feature there was the office of *justicia mayor*, a hereditary and immovable official who heard complaints, in parliament, against the king and his officials or of violations of charters and rights. At one period the Aragonese *Cortes* claimed the right to depose the king if it so wished, but the latter, in practice, had more power than in theory, for only he could initiate legislation. Unlike any other peninsular parliament, the *Cortes* of Navarre voted the customary taxes as well as extraordinary subsidies.

All these assemblies survived until the 18th century, but long before then they were dead politically. In 1700, for example, the *Cortes* of Castile had not been summoned since 1663, while the assemblies of Catalonia and Valencia had last met in 1640 and 1645 respectively. The situation was unaltered by the change of dynasty; indeed, the *Cortes* of Aragon and Valencia in 1709, and that of Catalonia in 1724 were merged with the *Cortes* of Castile. The Bourbon kings viewed the *Cortes* merely as a rubber stamp and this attitude fairly characterized its position until the 19th

century. For the development of the *Cortes* in the constitutional era, see *SPAIN: History*.

**CORTEX**, the outer portion of various structures in the biologic world. It is sometimes used figuratively. In botany it means the rind, bark or outer portion of the stalks of a variety of growths. Medicinally it is employed to describe the origin of certain drugs such as quinine from cinchona bark. In the medical sciences it is used to designate the outer portion of various organs such as the brain, kidney, adrenal glands, etc., as distinguished from the inner substance. The cortex usually lies just beneath or within the covering layer or membrane or capsule if one is present.

(F. L. A.)  
**CORTI, LUIGI, CONTE** (1823–1888), Italian diplomatist, foreign minister at the time of the congress of Berlin, was born at Gambarana (Pavia) on Oct. 28, 1823. Early involved with Benedetto Cairoli in anti-Austrian conspiracies, he was exiled to Turin, where he entered the Piedmontese foreign office in 1846. After serving in the campaign of 1848, he was in 1850 appointed secretary of legation in London, after which he was minister in Stockholm (1864), Madrid (1867), The Hague (1869), Washington (1870), and Istanbul (1875). Called by Cairoli to the direction of foreign affairs in 1878, he took part in the congress of Berlin, but declined Lord Derby's offer for an Anglo-Italian agreement in defense of common interests. At Berlin he sustained the cause of Greek irredentism, but otherwise remained isolated and incurred the wrath of his countrymen by returning to Italy with "clean hands." In Oct. 1878 he resigned. In 1881 he was sent to Istanbul by Cairoli, where he presided over the futile conference on the Egyptian question. In 1886 he was transferred to London as ambassador, but he was brusquely recalled by Francesco Crispi in the following year through a misunderstanding. The shock may have led to his death in Rome on April 9, 1888.

**CORTINA D'AMPEZZO**, a mountain resort of the Dolomites, province of Belluno, Veneto region, northern Italy, is situated in a beautiful hollow among fir-covered mountains on the left bank of the Boite river, 74 km. (46 mi.) N. of Belluno by road. Pop. (1961) 8,134 (commune). Its altitude is 4,016 ft. The town is dominated by its modern Gothic church whose tall bell tower plays chimes identical with those of Westminster abbey, London. The huge Olympic ice stadium and the two artificial ice tracks were built for the seventh winter Olympic games, held there in 1956, and at nearby Zuel is the Olympic ski-jumping chute. Cortina is on the railway from Pieve di Cadore to Dobbiaco. There is much local work in wrought iron, filigree and inlaid wood, especially cuckoo clocks. Cortina is one of the towns which make up the Great Community of Ampezzo and the people still retain their national costumes and Raetic or Ladin language.

(M. T. A. N.)

**CORTISONE**, one of several hormones secreted by the cortex (outer layer) of adrenal glands. Cortisone is useful in treating adrenal cortical insufficiency (Addison's disease) in man. Beginning in 1948, it was found clinically useful in suppressing the symptoms of rheumatoid arthritis and related diseases, certain allergies, acute leukemia, and certain inflammatory conditions of the eye and skin. Large doses are required. It does not cure these diseases. Sometimes the therapeutic use of cortisone causes gastric ulcers, edema, diabetes, hypertension, hirsutism, psychic disorders, etc., making it necessary to stop this type of therapy. Hydrocortisone, a somewhat more potent adrenocortical hormone, has similar therapeutic effects and the same limitations. Similar corticoid effects can be obtained by administration of adrenocorticotropin (ACTH), secreted by the anterior pituitary, which stimulates the adrenal cortex to secrete cortisone and hydrocortisone. The clinical use of these natural hormones has been largely superseded by synthetic derivatives of hydrocortisone that are more potent and suppress the symptoms of disease with fewer side effects. See *STEROIDS*; see also references under "Cortisone" in the Index volume.

(D. J. I.)

**CORTLAND**, a city of central New York, U.S., on the Tughiogga river midway between Syracuse and Binghamton; the largest community in, and seat of Cortland county. Originally part of the Phelps and Gorham purchase (1788), Cortland was first

settled in 1791. It was incorporated as a village in 1853 and as a city in 1900.

Cortland's diverse manufactures include industrial wire cloth and netting, wire, nails, forgings and stampings, motor trucks, women's foundation garments and various precision mechanisms. Dairying is the predominant agricultural activity of the area, and sales of cattle, poultry, eggs and maple sirup are significant.

The State University College at Cortland, founded as a State Normal School (1868), is part of the State University of New York. Winter sports and proximity to the Finger lakes are among the area's attractions. Three miles north is the village of Homer, the "Homeville" of the novel, motion picture and radio series *David Harum*.

For comparative population figures see table in *NEW YORK: Population*.

(R. C. HE.)

**CORTONA, PIETRO DA** (PIETRO BERRETTINI) (1596–1669), Italian painter and architect, one of the leading exponents of baroque art, was born at Cortona on Nov. 1, 1596. He created great illusionistic ceiling decorations at Rome in the Palazzo Barberini and the Chiesa Nuova, and in the Palazzo Pitti at Florence. Cortona built at Rome the church of SS. Martina e Luca and the façade of Sta. Maria della Pace and submitted in 1664 an unsuccessful design for the Louvre at Paris. With G. D. Ottonelli he wrote a treatise on the iconography of religious art, *Trattato della pittura e scultura, uso et abuso loro* (1652). He died at Rome on May 16, 1669.

(D. R. CN.)

**CORTONA**, a city of central Italy, region of Tuscany, province of Arezzo, is situated at the end of the Val di Chiana on the south slope of the Colle di San Egidio and on the right bank of the Esse river, 120 km. (75 mi.) S.E. of Florence by road. Pop. (1961) 25,872 (commune). The chief streets are wide and flat but the smaller ones are steep. There are several fine squares, and from the Piazza del Duomo there is an excellent view of the Chiana valley and Lake Trasimeno. The medieval walls survive, built on top of Etruscan walls. The cathedral has a partly Romanesque west front, a Renaissance-type bell tower and a fine portal by Giuliano da Sangallo (15th century). It contains paintings by Luca Signorelli, who was born in Cortona, and a magnificent Greco-Roman sarcophagus of an unknown warrior. In front of the cathedral is the church of Gesù (15th century), now a museum. It consists of one church superimposed on another. The upper church has a fine carved wooden ceiling by Michelangelo Leggi (1536). Notable among the exhibits is a painting of the Annunciation by Fra Angelico. The churches of S. Domenico, S. Antonio and S. Francesco are fine Gothic. The Romanesque Gothic church of Sta. Margherita and the church of the Madonna del Calcinaio are also noteworthy. The railway station is at Camucia, 4.5 km. (2½ mi.) away on the main line from Florence to Rome. Agriculture and stock raising are the main occupations. Once a malarial marsh, the Val di Chiana was drained and produces some of the best cattle in Italy.

The Roman Corito, the town was probably of Umbrian origin but was later an important Etruscan magisterial centre. In Roman days Hannibal passed by it to his victory at nearby Lake Trasimeno (217 B.C.), and in A.D. 405 it was taken by the Goths. It emerged from a long period of obscurity in 1202, when it was a free commune. It was sacked by Arezzo in 1258. Cortona recovered and had its own mint as well as becoming an episcopal see in 1325. After a long period of peace it was besieged in 1529 by the armies of Clement VII and Charles V, and thereafter joined the grand duchy of Tuscany. In World War II it was captured by Allied forces in July 1944.

(M. T. A. N.)

**CORTOT, ALFRED DENIS** (1877–1962), French pianist, conductor and teacher known for his poetic interpretations of the later romantic composers, was born at Nyon, Switz., on Sept. 25, 1877. He studied the piano at the Paris Conservatoire under Louis Diémer and, after gaining experience as assistant conductor at Bayreuth, conducted the first French performance of Wagner's *Götterdämmerung* (1902). He founded the Société des Concerts and the Paris Orchestre Philharmonique. In 1905 he formed a trio with Jacques Thibaud and Pablo Casals, and in 1918 founded

the École Normale de Musique in Paris where his piano classes had a wide influence. Cortot published works on piano technique, a historical survey of French piano music, and edited the works of Chopin and Schumann. He also made one of the finest private collections of musical autographs. About 1950 he retired to Lausanne, Switz., where he died on June 15, 1962.

**CORT VAN DER LINDEN, PIETER WILHELM ADRIAAN** (1846–1935), Dutch Liberal statesman, prime minister during World War I, was born at The Hague on May 14, 1846. Up to 1881 a solicitor at The Hague, from then to 1897 professor of economics at Groningen and Amsterdam, he started reuniting the Liberals on a program of social reform in 1886. He was minister of justice in the cabinet that succeeded in enacting much of this program (1897–1901). In 1902 he was made a member of the state council. In 1913 Cort van der Linden formed an extraparlimentary cabinet, which during World War I succeeded in bringing about a revision of the constitution. In 1917, this settled both the franchise and the school issues, which for half a century had dominated Dutch politics. Proportional representation, with universal male suffrage, was introduced; and private denominational schools were put on the same financial footing as public secular ones. After his resignation in 1918 Cort van der Linden was again appointed a member of the state council. He died at The Hague on July 15, 1935. (F. DE J.)

**CORUM**, the chief town of the *il* (province) of Corum, Turk., altitude 2,300 ft., is situated on the edge of a plain, almost equidistant from Amasya and Yozgat on the main road to the Black sea coast at Samsun, 130 mi. N.N.E. of Ankara. Pop. (1960) 34,629. The country around is fertile and extensively cultivated; cereals, fruits, tobacco and opium poppies are the chief crops. Corum is an important hand-spinning and weaving centre. Manufacturing of copper utensils and leather is also carried on. The ancient Euchaïta, 15 mi. E., was attacked by the Huns in 508 and became a bishopric at an early period. It contained the tomb of St. Theodore, who was reputed to have slain a dragon in the vicinity and became one of the great warrior saints of the Greek church. The *il* of CORUM has a population of 446,389 (1960). The chief *ilceler*, or *kazas*, are Alaca, Iskilip, Mecitozu, Osmancik and Sungurlu. (N. TÜR.; S. ER.; E. TÜR.)

**CORUMBÁ**, a city and river port (1960 pop. 36,744) in the state of Mato Grosso, Brazil. Situated on the Paraguay river at 360-ft. elevation, and fronting on Bolivia, the town was founded as a military outpost and colony in Sept. 1778 by Luis de Albuquerque. Corumbá's position was enhanced by the opening of the Paraguay to international commerce following the Paraguayan War (1865–1870) when it became terminus of river craft from Buenos Aires and Asunción. The buttes of Morro do Urucum to the south contain vast deposits of manganese and iron, mined since the 1940s. Corumbá produces animal products such as hides and dried beef, and is the leading entrepôt centre in southern Mato Grosso. It is a junction of air routes and has railroad connections with São Paulo and Santa Cruz, Bolivia. (J. L. TR.)

**CORUÑA, LA** (often in English CORUNNA; French LA COROGNE; English formerly THE GROVNE), capital of the province of the same name occupying the northwest corner of Spain, lies on Ría de la Coruña (Corunna bay), an inlet of the Atlantic ocean. Pop. (1960) 177,502 (mun.). A peninsula jutting northward separates Orzán bay on the west from the harbour on the east. The old town (Ciudad Vieja) occupies an eastern spur of the peninsula; the modern city (Ciudad Nueva or Pescadería "fishing quarter") stands on the low isthmus joining the peninsula to the mainland and on the mainland itself. A feature of the houses is their *miradores*, or window balconies glazed for protection against the wind. In the old town are the early 12th-century church of Santiago and the church of Santa María del Campo (13th century but badly restored). The church of Santo Domingo is in 18th-century Galician baroque; south of it in the Jardín de San Carlos overlooking the harbour is the granite tomb of Sir John Moore. About 2½ km. (1½ mi.) northwest of the old town, near the end of the peninsula, is the "tower of Hercules." It is supposed to have been built by the Phoenicians but was probably a Roman lighthouse dating from Trajan's reign. It commands

a fine view and still serves as a lighthouse.

Separating the old and new towns is the wide Plaza de María Pita, named after a heroine who displayed great bravery during the English attack of 1589. Near the Alameda gardens with their palms and orange trees is Canton Grande; a tablet on No. 13 marks the house where Sir John Moore died. Corunna is a popular summer resort and has excellent bathing beaches on Orzán bay and at Santa Cristina, 5 km. (3 mi.) S. The town has streetcar and bus services and is linked by rail with Madrid and with Oporto in Portugal. It has schools of navigation and agriculture, an arsenal and barracks.

Because of its position near a great sea route between northwest Europe and South and Central America, Corunna is one of the chief ports of northern Spain. The sheltered harbour can accommodate ocean-going vessels; it is a regular port of call for several shipping lines and is the chief Spanish passenger port for Cuba and South America. Corunna is an important fishing centre for sardines, herrings, haddocks and conger eels, and has a salting and canning industry. It also exports farm produce (especially onions and potatoes), and its imports include coal, salt and manufactured goods. There is a state tobacco factory in the southern suburb of Santa Lucia and shipyards for building fishing vessels.

**History.**—Under the Roman empire, Corunna was the port of Brigantium, but its present name is probably derived from that of Coronium by which it was known in the middle ages. In 1370 it was for a short time occupied by the Portuguese. In 1386 John of Gaunt landed there to conquer Galicia in pursuit of his claim to the kingdom of Castile. Philip II of Spain sailed from Corunna in 1554 to marry Mary Tudor of England, and in June 1588 most of the ships of the "invincible armada" despatched by him against England were forced by heavy squalls to take refuge in the port. In the following year an expedition sent in reprisal under Sir Francis Drake and Sir John Norris burnt the shipping at Corunna and sacked the lower part of the town. In 1815 and 1820 it was the scene of antimonarchist risings; in 1823 following a siege it was taken by French troops engaged in restoring the reactionary rule of Ferdinand VII. In 1836 it was captured by the Carlists (adherents to Don Carlos; see SPAIN; History). Corunna suffered heavily when Spain was deprived of Cuba and Puerto Rico by the Spanish-American War of 1898, for it had hitherto had a thriving trade with those colonies. Nationalist troops captured it early in the Civil War of 1936–39.

To many English-speaking people Corunna is familiar chiefly through *The Burial of Sir John Moore after Corunna*, a famous funeral elegy written in 1816 by the Irish poet Charles Wolfe (q.v.). Moore, commanding the British forces in Spain, was toward the end of 1808 advancing to relieve the pressure on the Spaniards by attacking Marshal Nicolas Jean de Dieu Soult on the Carrion river when he learned that the French had cut off his retreat into Portugal. (See PENINSULAR WAR.) He therefore withdrew on Corunna—a march of more than 200 mi. across the Cantabrian mountains in midwinter. The supply and transport services were inadequate and British losses through straggling and sickness were heavy, but on Jan. 11, 1809, Moore reached Corunna to find that the British fleet had not yet arrived. He chose as his main position the Monte Mero ridge straddling the road by which Soult must approach, about 3 km. (2 mi.) S. of the harbour. Soult, with about 16,000 troops opposed to Moore's force of about 15,000, attacked on Jan. 16. The initial advantage lay with the British but unfortunately a round shot struck Moore from his horse, carrying away his left arm; knowing his wound to be mortal he handed over command to Sir John Hope and was carried from the field. At evening he died. The battle flickered out; neither side could claim a victory (each had lost about 900 men) and the British were able to embark next day unmolested in the fleet which had by then arrived. At dawn Moore, "his martial cloak around him," was buried in the ramparts of the citadel; the place was later laid out as a garden. (See also MOORE, SIR JOHN.)

**Corunna Province.**—The province, until 1833 part of the captaincy-general and former kingdom of Galicia (q.v.), has a population (1960) of 991,729, and an area of 7,876 sq.km. (3,041 sq.mi.). It has a rocky coast with deep indentations

formed by drowned valleys. These (Santa Marta, Ferrol, Corunna, Corcubión, Arosa bays) afford sites for sheltered ports but the coast is dangerous because of frequent winter gales and fogs in winter and spring. Cape Finisterre (the Promontorium Nerium of the Romans), a huge granitic mass 100 km. (62 mi.) S.W. of Corunna by road, is one of the chief European headlands.

The interior of the province is mountainous but seldom exceeds 1,500 ft. elevation and is drained by many short rivers. The climate is mild and equable but the rainfall is the heaviest of any Spanish province (Santiago de Compostela, 66 in. annually). The slopes are covered with woods (oak, chestnut) and pastures and in the valleys beans, onions, potatoes and fruit are grown for export. The broken nature of the country discourages cereal growing but in limited areas heavy crops of maize (corn), wheat and rye are obtained. The local wines are heady, rough and of inferior flavour. The breeding of pigs and cattle is important, though the export of livestock, once considerable, declined because of foreign competition. A little tin, tungsten, copper and lignite are mined and Vimianzo near the west coast was once famous for its gold mines. Along the coast there are valuable fisheries of sardines, lobsters, hake and other fish. The chief exports are farm produce and fish; the imports coal, petroleum fuels, salt fish, timber, hides, salt and manufactured goods.

The principal ports are Corunna and El Ferrol (*q.v.*). The chief inland town is Santiago de Compostela. Air services link Santiago with Barcelona, Bilbao and Madrid but other communications are sparse. Except for a main railway line from Corunna through Lugo to Madrid, with a branch northward to El Ferrol and a southward line through Santiago to Vigo and Oporto, the inhabitants are dependent on somewhat indifferent roads.

See O. Pedrayo, *Guía de Galicia* (1954); Martínez-Barbeito, *Galicia* (1957).

**CORUNDUM** is a mineral composed of aluminum oxide,  $Al_2O_3$ , and in its finer varieties forms valuable gems such as ruby and sapphire (*qq.v.*). The massive form in combination with iron oxides and spinel is called emery (*q.v.*). The name corundum is believed to be derived from Hindi (*Karund*), the mineral first being identified from India.

Next to diamond, corundum is the hardest known mineral (9 on Mohs' scale), this being sufficient to separate it from all other minerals. The pure mineral is colourless, small amounts of impurities explaining the wide range of colours in nature. Ruby contains chromium, sapphire presumably iron or titanium; most corundum contains nearly 1% iron oxide. Zoisite, sillimanite, kyanite, margarite, damourite and hydrated alumina minerals are common alteration products. Corundum is used for bearings in fine machinery such as watches and motors and, as emery, for polishing. It is a prominent constituent of many refractories, in many instances being formed on firing. Artificial corundum (*q.v.*) has similar properties and has become the source of most pure alumina (*q.v.*) abrasives. Synthetic rubies and sapphires that defy detection by all but the expert are manufactured. Gem corundum has come principally from Ceylon, Burma, Thailand, Montana, and Queensland, the stones being recovered from metamorphic rocks and placer deposits. Corundum has also been mined in Ontario, South Africa, the Ural mountains, South Carolina and other places.

Corundum crystallizes in the hexagonal system (rhombohedral class) showing considerable variety of habit, the commonest being acute hexagonal bipyramids, sometimes in barrel-shaped forms, or tabular owing to predominance of the basal form. Corundum has no true cleavage but a parting parallel to the base and the rhombohedron, the latter a plane of lamellar twinning, sometimes secondarily produced through pressure. Density is 3.95 to 4.0, refringence (refraction) as high as 1.7686 (sodium light), melting point  $2,040^\circ C.$ , dielectric (nonconductive) constant about 10. Corundum resists attack by acids and alkalis. Alumina-rich melts have great power of crystallization, making it difficult to preserve glasses of such composition. Single crystal alumina bodies can be formed into rods and bent at high temperature, yet retain monocrystallinity. No other natural  $Al_2O_3$  mineral is known but essentially anhydrous oxides are encountered in labora-

CORUNDUM CRYSTALS FROM TRANSVAAL, SOUTH AFRICA, IN BARREL AND TABULAR FORMS

tory studies, differing distinctly from the  $\alpha-Al_2O_3$  or corundum phase into which they transform on heating to about  $1,200^\circ C.$  So-called  $\beta-Al_2O_3$  is actually  $Na_2O \cdot 11Al_2O_3$ , and is not a dimorph of corundum as was long thought.

Corundum is widespread in nature, occurring in igneous, sedimentary and metamorphic rocks. Certain rocks of the syenite clan commonly carry appreciable corundum. The occurrence of corundum in quartz-bearing igneous rocks is rare and is considered anomalous from thermodynamic considerations. See also GEM.

(W. K. GR.)

**CORUNDUM, ARTIFICIAL**, has the same properties as natural corundum (*q.v.*) or  $\alpha$ -alumina. Probably the most important advance in the abrasive field was the development of techniques around 1900 for the large-scale production of artificial corundum. In addition to being very hard (9 on Mohs' scale) artificial corundum is exceedingly strong. It fractures in such a way that new, sharp cutting points are continually formed. It has low specific heat and thermal expansion. These properties adapt it particularly to the working of materials of high tensile strength, such as the various steels, which is the most important use for abrasives. The grains are used extensively in all kinds of grinding and polishing wheels, coated paper, cloth and disks, and to a lesser extent as loose grains. Specific applications are exemplified by the following: automatic and hand-grinding operations of all types, for snagging steel castings, surface and internal grinding, honing, tool and cutter grinding, polishing articles such as cutlery and hardware; cut-off saws; loose grain polishing of plate glass and metallurgical specimens; in dental and other air-drills. Fused alumina is employed as grog, in special refractory concrete. Fine bearings, record-player needles, and other uses employ artificial corundum crystals.

Artificial corundum sometimes is known as fused bauxite, or fused alumina, and by trade names such as Alundum, Borolon, Aloxite, Lionite, and Oxaluma. Fused bauxite is made by melting calcined bauxite (composition approximately 86%  $Al_2O_3$ , <7%  $SiO_2$ , 3%  $Fe_2O_3$ , 3%  $TiO_2$  and <1% water) with coke and metallic iron in electric arc furnaces of several tons capacity, at a temperature of about  $2,200^\circ C.$  Hanging graphite electrodes carry alternating current to the melt. Furnaces are of two types: (1) batch, a removable conical shell on a flat, carbon-lined, wheeled base, (2) continuous, tilting furnaces from which small pigs can be poured. Furnace shells are water-cooled. Large continuous furnaces may operate at several thousand kilowatts.

In batch furnacing the coke reduces oxide impurities to elements, which unite with the added iron to form magnetic ferro-silicon; this settles to the bottom, leaving the alumina in a much purified state. Carbon is eliminated as carbon monoxide (CO) which burns to the dioxide ( $CO_2$ ) on leaving the furnace. When the furnace is fully charged the electrodes are withdrawn, and before long the shell can be lifted off to allow the several ton ingot to cool. As it solidifies, the alumina crystallizes into a solid mass of large irregular crystals. Both batch and continuous procedures can be controlled to yield a product containing roughly 95% alumina, 1.5% silica, 0.5% ferric oxide, and 3% titania.

The lump abrasive is crushed and ground in jaw crushers, rolls, and ball mills, followed by removal of residual magnetic material by magnetic separators. Grading into a great variety of size fractions, from 6 mesh per inch to micron sizes, is carried out by vibrating screens, hydroclassifiers, and air separators. Fused bauxite is commonly deep reddish-brown and translucent.

The production of white abrasive from Bayer process calcined alumina (which itself is largely artificial corundum) has continuously expanded. This employs essentially the same process as for calcined bauxite (*q.v.*), but the starting purity of the alumina (99%) obviates the need of separation of silicon and iron. Bayer alumina contains some soda, part of which combines with

alumina to form so-called  $\beta$ -alumina, actually  $\text{Na}_2\text{O} \cdot 11\text{Al}_2\text{O}_3$ , which is brittle and objectionable in the final product. It may be removed from the cooled batch pig by cobbing the central and upper zones where it tends to segregate during crystallization. Other impurities imparting colour to the product are also objectionable. White fused alumina is crushed and sized as is fused bauxite. A special process involving fusion and crystallization in a water-decomposable matrix allows the development of small, sharp, separate crystals that can be recovered as such, avoiding the need of heavy crushing and sizing. Artificial corundum is also produced as a specialty product by slow accretion and controlled growth on a boule in an oxyhydrogen flame. See GEM: Synthetic Gems.

See A. W. Wilkinson, "The Production of Synthetic Abrasives," *Canadian Chemical Processing*, vol. 38 (Sept. 1954); A. L. Ball and A. A. Kline, "Applications of Abrasives," *A. S. T. M. Stand.*, Bull. 191 (July 1953).

**CORVALLIS**, a city in western Oregon, U.S., at the head of navigation of the Willamette river, 85 mi. S.W. of Portland; seat of Benton county. Founded as Marysville in 1850, the name was changed to Corvallis ("heart of the valley") in 1853. It was incorporated in 1857. Essentially nonindustrial, the community centres its cultural, social and athletic activities around Oregon State college, founded in 1858, oldest and largest of the state's institutions of higher education. The unique Horner Museum of the Oregon Country is located there. Camp Adair of World War II, a short distance from Corvallis, is the site of an air force installation of the North American Air Defense command (NORAD). For comparative population figures see table in OREGON: Population. (J. W. E.)

**CORVÉE**, a term used in feudal law to designate the regular work that vassals owed their lord. It came to mean a contribution and in medieval Latin it meant labour exacted by the authorities. From this was derived the Old French *corvée*, adopted without change by the English.

In France the distinction was made between the *corvées réelles* (genuine), those days of work due in return for the property right, and *corvées personnelles* (personal), due by reason of residence and usually confined to road work. The term has retained its meaning as a payment in kind or in work levied on the inhabitants of a parish for the upkeep of local roads. It has also come to be used figuratively as a military term to describe fatigue duty, and thence extended to describe any drudgery or any work done reluctantly.

The use of the *corvée* as a system of obtaining labour dates from ancient times. Under the Roman empire, personal services were due from certain classes of the population to the state and also to private proprietors. Obligations were imposed on freedmen as a condition of their enfranchisement and in the country usually took the form of unpaid work on the landlord's domain. The semiservile *coloni* were bound, besides paying rent in money or kind, to do a certain number of days' unremunerated labour on that part of the estate reserved by the landed proprietor. The state also exacted personal labour from certain classes in lieu of taxes for such purposes as the upkeep of roads, bridges and dikes. The inhabitants of the various regions were responsible for the maintenance of the posting system, for which horses, carts or labour would be requisitioned. Under the Frankish kings, who followed the Roman tradition, this system was preserved. Between the 6th and 10th centuries the Gallo-Roman estates were converted to the feudal model, and the officials of the Frankish empire developed into hereditary feudal nobles. They evolved the system of the *corvée* as it existed throughout the middle ages in Europe.

Similar labour obligations existed in other parts of the world. In Japan the *yo* system of imposing compulsory labour on the farmers was incorporated in the tax system in the 7th century A.D. This system included *yo* (labour tax) of 10 days per year; *cho* (tax on materials produced) of 10 days per year; and *so* (land tax) of 20 days per year. Certain articles such as silk cloth might be paid in lieu of the forced labour. In Egypt it is said that 100,000 men were made to work 3 months per year for 18 years to build the Great Pyramid. The *corvée* was used for centuries

to obtain labour to remove the mud left at the bottom of the canals by the rise of the Nile. The *corvée* system was enforced with the *kurbash*, a strip of hippopotamus hide used for flogging. When the use of the *kurbash* was outlawed in 1883 by British authorities, enforcement of the *corvée* became difficult. It was partially abolished in 1886 and by 1892 was completely eliminated for dredging purposes. However, there still remained an emergency obligation to guard the banks of the Nile river to prevent inundation.

Although the *corvée* applied originally to feudal dues, it later became synonymous with statute labour, a specified amount of labour on public projects required by law. The *corvée* was revived when money payment did not provide sufficient labour for public projects. This might occur when public revenues were low, when there was a shortage of labour, or when the available labour did not customarily seek outside employment. It was revived in France in 1726 for road work and was finally abolished during the French Revolution. In England and Scotland statute labour on roads was used from the 16th through the 19th centuries, by which time the turnpike system had begun to take over the main roads. Compulsory labour was also enforced in the American colonies, able-bodied male inhabitants being required to contribute days of labour on public works. In the northern colonies all male inhabitants were liable but in the southern colonies the obligation was generally limited to labourers, servants and slaves. The obligation to work on the roads was carried down to the 20th century in many localities, although a money payment was accepted in lieu of labour. This requirement was held in 1916 not to violate the U.S. constitutional prohibition against involuntary servitude and was considered in the same category as training in the militia.

The basic distinction between the *corvée* and forced labour is that the *corvée* is a general and periodic short-term obligation; forced labour is usually prescribed for a long or indefinite period as a method of discipline or discrimination on a highly selective basis. The Forced Labour convention adopted by the International Labour organization (ILO) in 1930 defined forced labour as "all work or service which is exacted from any person under the menace of any penalty and for which the said person has not offered himself voluntarily." Forced labour for private employers was outlawed. Forced labour for public purposes was allowed during a transitional period for the purpose of work in the public interest; as a form of tax or as a personal service exacted by chiefs who are duly recognized; for portage; and in agriculture to protect against famine. The ILO definition of forced labour specifically excluded military service, normal civic obligations of a citizen, work or service imposed by court decision after due process of law and work required during emergency conditions such as flood or earthquake.

The 1930 convention applied primarily to colonial territories, and it became outmoded as a result of the social evolution that took place in these territories. In 1957 the ILO adopted the Abolition of Forced Labour convention which reflected a fundamental change in the purpose of forced labour. The later convention was directed chiefly at such countries as Albania, Bulgaria, the People's Republic of China, Czechoslovakia, Hungary, Poland, Rumania, the U.S.S.R. and Yugoslavia, which after World War II had instituted a national policy for the utilization of involuntary labour. In the 1957 convention the ILO outlawed any form of forced labour "(a) as a means of political coercion or education or as a punishment for holding or expressing political views ideologically opposed to the established political, social or economic system; (b) as a method of mobilizing and using labour for purposes of economic development; (c) as a means of labour discipline; (d) as a punishment for having participated in strikes; (e) as a means of racial, social, national or religious discrimination."

In the People's Republic of China there are both types of compulsory labour. Civilians may be drafted to spend ten days a year on road work, repairing dikes, etc. Permanent forced labour is recruited from both ordinary convicts and "counterrevolutionaries," and is used for water conservation projects, railway construction and agriculture.

Compulsory labour in Africa is generally limited to the con-

tions allowed by the ILO convention. It was instituted by Europeans to counteract the African's resistance to leaving the village to work for wages. In French West Africa the *corvée* was applied until 1946; all able-bodied African males were obliged to work about 15 days a year on public works. In Belgian territories, compulsory agricultural work up to 45 days per year, 15 days of public works and liability for portage existed in the 1950s, although an individual might substitute a money payment. Forced labour is forbidden in all British territories in Africa, although portage service to native chiefs and compulsory agricultural work may still be found. Road repairs and portage are allowed in Liberia. In South Africa, the hiring of prisoners to private individuals for agricultural labour is common. Unpaid labour could be requisitioned in Portuguese Africa for public works, and contract labour for private employers could be recruited among Africans who could not prove financial responsibility.

**CORVETTE**, a type of ship-rigged sloop of war in the days of sail. Corvettes usually carried only one tier of guns and in size ranked below frigates. The last of the true corvettes in the British navy were scrapped in 1903, but the name was revived during World War II to denote lightly armed and highly maneuverable vessels designed for antisubmarine escort duty. These new corvettes possessed many of the capabilities of destroyers but were smaller and were less expensive to build and operate. More than 150 were built or begun in Britain and Canada, and some were transferred to the United States under reverse Lend-Lease. Some of the "Castle" class of corvettes were in the British fleet in 1959, but had been redesignated antisubmarine frigates, 2nd rate. Typical characteristics were as follows: displacement, 1,580 tons, fully loaded; length, 252 ft.; beam, 37 ft.; draft, 15½ ft.; speed, 14 knots. Their complement was 100 officers and men.

(J. B. Hn.)

**CORVIDAE**, the family of birds that includes jays, magpies, ravens and crows, said to be the cleverest of the perching birds. See CROW; JAY; MAGPIE; RAVEN.

**CORVUS, MARCUS VALERIUS** (c. 370–270 B.C.), Roman general. According to legend a raven (*corvus*) settled on his helmet during his combat with a gigantic Gaul and distracted the enemy's attention by flying in his face (349). He was twice dictator and six times consul, and occupied the curule chair 21 times. In successive campaigns he defeated the Volsci, the Samnites, the Etruscans and the Marsi. Not all the victories attributed to him by tradition can be accepted.

See Livy, bk. 7–10 *passim*.

(H. H. Sn.)

**CORWIN, THOMAS** (1794–1865), U.S. congressman, cabinet member and diplomat, was born in Bourbon county, Ky., on July 29, 1794. In 1798 his father, Matthias Corwin (1761–1829), moved to what later became Lebanon, O., where the son worked on a farm, read widely and in 1817 was admitted to the bar. With his remarkable wit and intelligence Corwin became an immediate success as a lawyer. During the 1820s he served three terms in the Ohio general assembly, but after 1831 he turned to national politics, identifying himself with the Whig party. He was a member of the national house of representatives, 1831–40; governor of Ohio, 1840–42; U.S. senator, 1845–50. His most memorable speech in the senate was his attack on the Mexican War delivered on Feb. 11, 1847. He was secretary of the treasury (1850–53) in the cabinet of President Fillmore. Because of his innate conservatism, he entered the Republican party reluctantly, and as a member of that party returned to the national house of representatives in 1859. During the crisis of 1861 he served as chairman of the congressional committee of thirty-three, which sought a compro-

mise between North and South. Corwin was U.S. minister to Mexico in 1861–64 and was instrumental in preventing Southern agents from gaining support from the Mexican government. He died at Washington, D.C., Dec. 18, 1865. (N. A. G.)

**CORYATE, THOMAS** (1577?–1617), English traveler and writer of early books of travels, was born at Odcombe, Somerset, c. 1577, where his father was rector. Educated at Winchester college and at Gloucester hall, Oxford, he became a kind of court fool, eventually entering the household of Prince Henry, the eldest son of James I. In 1611 he published *Coryats Crudities*, an account of the travels in France, Italy and other countries, covering nearly 2,000 mi. on foot, which he had undertaken in 1608.

Verses written by Ben Jonson, John Donne, George Chapman, Michael Drayton and other poets in mock praise of the author were added to the volume at the command of Prince Henry, and afterward reprinted as the *Odcombian Banquet* (1611). In the same year Coryate published a second work of the same nature as his first, *Coryats Crambe*. In 1612 he set out on another journey, again mostly on foot, to Greece, the Holy Land, Persia and India. He sent home from Agra and Ajmere an account of his adventures. Some of his letters were published in 1616 under the title *Thomas Coriate Traveller for the English Wits: Greeting*, and some fragments of his writings were included in *Purchas His Pilgrimes* (1625). Coryate's writings are not without humour and show a genuine, if uncritical, interest in antiquities. He died at Surat, India, in Dec. 1617.

(P. Dw.)

**CORYBANT**, one of the Corybantes, daimones with much the same relation to the Asiatic Great Mother of the Gods (*q.v.*) as the Curetes (*q.v.*) bear to Zeus. From their first appearance in literature, they are often identified or confused with the Curetes, and are distinguished only by their Asiatic origin and by the more pronounced orgiastic nature of their rites. Various accounts of their origin are given: they were earthborn sons of Cronus, of Zeus and Calliope, of Rhea, of the Great Mother and a mystic father, of Apollo and Thalia, of Athena and Helios. Their names and number are vague and vary from one authority to another. It is known that they had a mystic cult and that a prominent feature of their ritual was a wild dance, which was claimed to have powers of healing mental disorder. It seems possible that originally they were priests or medicine men of ancient times, later thought of as superhuman.

In art the Corybantes appear, usually not more than two or three in number, fully armed and executing their orgiastic dance.

**CORYDON**, a town of southern Indiana, U.S., seat of Harrison county, located 20 mi. W. of Louisville, Ky. Corydon was settled about 1805 and was the capital of Indiana territory (1813–16) and of the state from 1816 until the capital was moved to Indianapolis in 1825. The convention which drafted the first constitution for Indiana met there in June 1816. Indiana's first statehouse stands in the public square. The Civil War battle of Corydon, in which Confederate raiders captured and held the town for a few hours, was fought between the forces of Gen. John H. Morgan and the Corydon home guards on July 9, 1863. The oldest continuous county fair in Indiana is held in Corydon yearly in September. Wyandotte cave is located 12 mi. west.

Corydon is the centre of an active agricultural area; its principal crops are poultry, eggs, beef and dairy cattle and burley tobacco. Industries include a furniture factory, a poultry processing plant and glassworks. The population is about 2,700.

**COS** (STANKO; Gr. Kos; Ital. Co; Turk. ISTANKOY; Lat. Cos), an island of Greece not far from the southwestern corner of Asia Minor, is the second largest of the Dodecanese (*q.v.*). Pop. (1951) 19,076, nearly all Greek. Area 282 sq.km. (109 sq.mi.). The island consists of three regions: an abrupt limestone ridge (anc. Prion, "the saw," from its jagged profile) along the eastern half of the south coast; a rugged peninsula (Kephala) at the west end; and a central lowland of fertile marls prolonged along the north coast to the ancient capital facing the mainland. Along the north slope of the Prion ridge copious deep-seated springs provide water for the town and for extensive irrigation. Cos lettuce is well known. The principal resources of Cos are its vineyards, figs and olives; wheat, barley and maize are grown,

though a considerable proportion of the arable land is left untouched. Melons, grapes and other summer fruits are exported in large quantities to Egypt, mostly in local sailing boats. Cotton, tobacco, sesame and silk are grown in small quantities. The capital, Cos (pop. [1951] 8,390), is on the northeast coast.

The medieval harbour is fit only for quite small vessels, but the roadstead is safe in most weathers and steamers call there. The ancient and medieval town round the harbour has a well-preserved fortress, founded by the Knights of Rhodes; in its walls are interesting architectural fragments. The famous plane tree in the market square has a circumference of about 30 ft. and its huge branches have to be supported by pillars. Of its age there is no certain knowledge; the popular tradition connects it with Hippocrates. The town is supplied by an aqueduct, about 4 mi. in length, from the fine ancient well house of Borinna high on Mt. Prion. The village of Pili has the fine Greek tomb of Charmylos, and at Kephala, site of the ancient town of Isthmos, is an outlying castle of the Knights of St. John. The prosperous village of Andimakhia is the corn market of the central lowland. The precinct of Asclepius (excavated in 1900-04 and later extensively restored), about 2 mi. from the town of Cos, consists of three terraces, containing temples, an altar, porticoes and other buildings and a medicinal spring; below is a large enclosure with porticoes. The earliest buildings on the middle terrace date from the 6th century B.C. The temple on the upper terrace, with an imposing flight of steps, is of the 2nd century B.C. After a destructive earthquake the whole site was remodeled by Xenophon, the physician who poisoned the emperor Claudius. The sanctuary was desolated by the earthquake of A.D. 554.

**History.**—Cos was settled by Dorian colonists from Epidaurus who worshipped Asclepius, whose sanctuary became a health resort and the first school of scientific medicine. In the 5th century B.C. it joined the Delian league. Usually its government was aristocratic, but in 366 a democracy was instituted. In 357-355 it resisted Athenian aggression, then fell for a few years into the power of Mausolus, prince of Halicarnassus. In the Hellenistic age Cos owed its prosperity to the friendship of the Greek dynasty of Egypt, who valued it as a naval outpost. As a seat of learning it was adopted for the education of Ptolemaic princes; among its most famous men were the physician Hippocrates, the painter Apelles and the poets Philetas and Theocritus (*qq.v.*). Like its neighbour Rhodes, Cos generally supported the Romans. In A.D. 53 it was made a free city. In 1315 it was occupied by the Knights of St. John, its castle, with that at Halicarnassus (Bodrum), serving as outer guard to Rhodes. In 1523 it passed under Ottoman sway and, having been occupied by Italy during the Tripoli war in 1912, it was formally ceded to Italy by Turkey in the treaty of Lausanne, 1924, and then to Greece in 1947.

See A. Philippson, *Die gr. Landschaften*, iv, pp. 288 ff. (1959). (X.; W. G. F.)

**COSA**, an ancient Etruscan city on the west coast of Italy near modern Orbetello, Grosseto province. The site immediately adjoins the southern neck of sand that joins Monte Argentario to the mainland. Probably not important in Etruscan times, in Roman times it was a dependency of Vulci, about 20 mi. distant.

In 273 B.C. a Roman colony was founded at Cosa. In 209 it was one of the Latin colonies that furnished supplies for the Second Punic War. Its inhabitants petitioned for new colonists in 199 B.C. In the 1st century B.C. its port, Portus Cosanus, which had already been used in the Punic and Social Wars, served as a station for the Roman fleet, and is probably to be identified with Portus Herculis (mod. Porto d'Ercole) on the opposite side of the bay and not with modern Porto Cosano. After this, although it remained populated until the 3rd century A.D., Cosa played no part in history. In the 5th century it is spoken of by Rutilius Claudius Namatianus as deserted and was perhaps devastated by the Visigoths. The name of Ansedonia was given to the ruins in the 11th century but it is not certain whether this indicates a new settlement.

The walls and 14 defensive towers of ancient Cosa can still be traced to the south and west of the town, and large sections are

well preserved. They are built of polygonal masonry of an archaic style. High antiquity has been claimed for these walls, but it is more probable that they were constructed during the first phases of Roman occupation in the 3rd century B.C.

See G. Dennis, *Cities and Cemeteries of Etruria*, vol. ii, pp. 245-262 (1878); D. Levi in *Studi Etruschi*, vol. i, p. 477 (1927). (W.M.C.)

**COSELEY**, an urban district (1895) in the Bilston parliamentary division of Staffordshire, Eng., lies in the Black Country (*q.v.*) between Birmingham and Wolverhampton. Pop. (1961) 39,535. The district includes Hurst Hill, Turlis Hill, Woodsetton, Foxyards, Princes End, Upper Ettingshall, Lanesfield, Parkfield and a part of Bradley. Ettingshall was settled before the Norman Conquest and Coseley itself was a coal and iron mining centre from at least the 17th century, while it is known that nails were made there in the 16th. But Coseley's modern industrial expansion dates from 1927 when the Wolverhampton-Birmingham road was cut, offering improved communications for manufacturers. Among the few old buildings in the area is High Arcal farm (early 17th century). The Beacon tower (mid-19th century) is a well-known landmark and Mons hill is a nature reserve. There is no more coal mining in the district; the main industries are metal founding, steel making, the making of electrical products, agricultural, textile and other machinery, and prefabricated buildings.

**COSENZA**, a town and archiepiscopal see of southern Italy, capital of the region of Calabria and the province of Cosenza, is situated in mountainous country on the Crati, 343 km. (213 mi.) S.E. of Naples by road. Pop. (1961, commune) 79,028. The oldest part of the town lies at the confluence of the Crati and Bussento and consists of a tightly packed concentration of houses and palaces climbing to the hilltop by typically narrow stair-step streets. This area is dominated by a partly Swabian and partly Angevin castle. North of the Bussento is the new part of the town. The chief buildings are the Romanesque and Norman cathedral (1185) and the churches of S. Domenico (13th century), S. Francesco di Paola, Cappuccinelle, Sta. Maria in Constantinopoli and Sta. Catarina, which have fine interiors and many art treasures. One of the exhibits in the museum is the flag of the unsuccessful expedition of the Bandiera brothers in 1844. The Accademia Cosentina was founded early in the 16th century by Aulo Parrasio. Railways run to Paola, Sibari, Crotona and Catanzaro. Agriculture (especially the production of cereals, wine, oil and fruit), furniture making and the production of wool and tannic acid are carried on.

During the Punic Wars the town (ancient Consentia) supported Hannibal. Alaric, king of the Goths, died there and is said to have been buried in the bed of the Bussento. The town passed in turn to the Byzantines, Saracens and Spanish until it was proclaimed a republic in 1799. Under the Bourbon kingdom of Naples it was the scene of uprisings culminating in the Bandiera brothers' abortive attempt. In World War II it was captured by the Allies on Sept. 8, 1943. (M. T. A. N.)

**COSGRAVE, WILLIAM THOMAS** (1880-1965), Irish statesman, who was president of the Irish Free State in the troubled years 1922-32, was born in Dublin on June 6, 1880, the son of Thomas Cosgrave, who was at one time a town councillor and poor-law guardian. William Cosgrave was attracted at an early age by the Sinn Féin movement. He became a member of the Dublin corporation in 1909, and was subsequently re-elected in the Sinn Féin interest. He joined the Irish Volunteers in 1913 and when that body divided in Aug. 1914, he was with the minority who refused to follow John Edward Redmond (*q.v.*). He took part in the Easter rising in 1916, and was afterward interned at Frongoch in Wales. In 1917, shortly after his return to Ireland, Cosgrave fought a by-election in Kilkenny city as the Sinn Féin candidate, and was elected by a large majority. Re-elected in Dec. 1918, this time for north Kilkenny, he was a member of the first *dail eireann* (assembly of Ireland) and became minister for local government in the first republican ministry. It was his task to organize a policy of non-cooperation with the British authorities and to build up an alternative system of local government. Like all other members of the republican ministry he was more than once imprisoned.

Cosgrave was a supporter of the 1921 treaty settlement with Great Britain and his speech in the debate on the treaty attracted attention. Later he became minister of local government in the newly formed provisional government. When, on Aug. 12, 1922, Arthur Griffith suddenly died and Michael Collins was chosen president in his place, Cosgrave became acting chairman of the provisional government. Ten days later Collins was shot and Cosgrave found himself at the head of a state fighting for existence. Until then he was little known in the country.

As soon as the newly elected *dail* could be summoned—and it could meet only behind closed doors and under a strong guard—Cosgrave made clear his view that the day of individual leadership was over and team work must take its place. In that anxious period he left much of the work, especially the carrying of the draft constitution through the assembly, to younger and more able subordinates. But he was always ready to shoulder responsibility and when tempers were roused he introduced a conciliatory spirit. He showed both breadth of view and a sense of humour, and endeavoured to reconcile the Protestant minority to the new Irish Free State. As president of the executive council of the Irish Free State, Cosgrave represented Ireland at the Imperial Conference in Oct. 1923; and a month earlier he was welcomed as Ireland's first spokesman at the assembly of the League of Nations. He restored settled government. The ministry for finance, which he took over at the outset, was transferred in 1923 to E. Blythe; the ministry for defense, which he took over in March 1924, in face of a threatened mutiny in the army, was handed over easily and without comment a few months later to a new minister. In his political career Cosgrave was not ambitious. He never sought to thrust his personality into the forefront, but he won a reputation for good sense and moral courage.

Under Cosgrave's guidance the country moved steadily to settled order; some industrial enterprises were launched with state aid, notably the Shannon electricity scheme. In the *dail* there was no serious opposition, since the party headed by Eamon de Valera which refused to take the oath prescribed in the treaty abstained from attendance. But neither Cosgrave nor his ministry enjoyed much popularity. Order is not enforced after a revolution without drastic measures, and taxation was heavy and sharply collected. Cosgrave seemed sure of a long tenure only because there was no alternative in sight. In July 1927, shortly after the general election, the assassination of Kevin O'Higgins, the vice president, produced a crisis. Very severe legislation against political associations of an unconstitutional character was introduced and a bill declaring that no candidature for the *dail* should be accepted unless the candidate declared himself willing to sit and to take the oath of allegiance. The result of this measure was that De Valera and his party decided to come in and, since this revolutionized the parliamentary situation, Cosgrave obtained leave to dissolve. The new election in Sept. 1927 left his party numerically the largest in the *dail* but without an over-all majority. He continued in office till De Valera's decisive victory at the general election of 1932. During these years Cosgrave's government made a significant contribution to the reshaping of British Commonwealth relations. In 1944 he resigned from the leadership of the Fine Gael Party. He died in Dublin on Nov. 16, 1965. See also *IRELAND, REPUBLIC OF: History*. (S. G.; P. N. S. M.)

**COSIN, JOHN** (1594–1672), English bishop, born in Norwich on Nov. 30, 1594, was educated at Norwich grammar school and Caius college, Cambridge. In 1624 he became prebendary of Durham and in the following year archdeacon of the East Riding of Yorkshire. His *Collection of Private Devotions* (1627), which is said to have prepared by command of Charles I, and his known friendship for Laud brought him under suspicion with the Puritans.

Cosin was appointed master of Peterhouse, Cambridge (1634), vice-chancellor of the university (1640) and dean of Peterborough (Oct. 1640). The Long parliament, however, deprived him of his benefices in 1641, and in 1642 he lost also the mastership of Peterhouse. He then joined the royal family in France, where he remained until the Restoration. Cosin was raised to the see of Durham in Dec. 1660, and was one of the revisers of the Prayer Book

(1661). He died in London on Jan. 16, 1672.

A collected edition of Cosin's works, forming five volumes of the *Library of Anglo-Catholic Theology*, was published between 1843 and 1855; and his *Correspondence* was edited by George Ormsby for the Surtees society (1868–70).

See P. H. Osmond, *Life of John Cosin* (1913).

**COSMAS OF ALEXANDRIA**, surnamed INDICOPLEUSTES ("the Indian navigator"), was an explorer, a theologian, a geographer and the author of a treatise on the universe based on biblical revelation. He flourished in the 6th century A.D., was probably a Nestorian Christian, and sailed around the shores of the Indian ocean. He later became a monk and wrote a description of his travels. Controversies about this work led to the composition of his *Topographia Christiana*, which, except for a few fragments of his commentaries on the Psalms and the Gospels, is the only part of his writings which has survived. The *Topographia Christiana* appears to have been written between A.D. 535 and 547 and was a controversial work, designed to prove from arguments of common sense the literal accuracy of the biblical picture of the universe. According to Cosmas, the universe is best illustrated by the Tabernacle of Moses, which is its replica in every detail. The earth is a rectangular plane, covered by the firmament, above which lies heaven. In the centre of the plane is the inhabited earth, surrounded by ocean, and beyond this the paradise of Adam. The sun, much smaller than the earth, revolves around a conical mountain to the north, and is thereby obscured each night. Cosmas is particularly scornful of those who believe in a spherical earth or in the existence of an Antipodean population. His idiosyncratic work is not representative of the general state of cosmographic theory among Christian philosophers in his day, and it had small influence on later writers. It is of interest as a curiosity of literature and for certain observations, made particularly in Abyssinia, which are incorporated incidentally to the main argument.

The *Topographia* will be found in J. P. Migne, *Patrologia Graeca*, lxxviii (1865); ed. with geographical notes by E. O. Winstedt (1909). English translation, with introduction and notes, by J. W. McCrindle (1897). (Wm. C. B.)

**COSMAS OF PRAGUE** (1045?–1125), dean of Prague cathedral and the earliest Bohemian chronicler. His *Chronica Bohemorum libri iii*, which contains the history and traditions of Bohemia up to nearly the time of his death, is the most important source of knowledge of the origin and development of the Bohemian state. The best edition is by B. Bretholz in *Monumenta Germaniae historica: Scriptores*, new series, vol. ii (1923).

See J. Loserth, *Studien zu Cosmas von Prag* (1880).

**COSMAS AND DAMIAN, SAINTS**, brothers, perhaps twins, the patron saints of physicians, of whose lives and martyrdom little is known with certainty. According to Christian tradition they were born and lived in Aegea in Cilicia in Asia Minor, and became distinguished physicians known not merely for their skill in medicine but also for their Christian charity in refusing payment for their services (for this reason they were given the surname *amargyroi*, the "silverless ones"). Their charity converted many to Christianity. Imprisoned during the persecution of Diocletian, they were tortured and finally beheaded (c. 303). By the middle of the 5th century their cult had become so widespread that churches were erected in their honour in various cities of the east, including Constantinople; and by A.D. 530 Pope Felix IV had erected a church in their honour in Rome. A variety of early accounts of their lives and martyrdom gave rise to many legends about them. Their feast day in the Eastern Church is Oct. 27; in the Roman Catholic Church it is Sept. 27. (R. P. N.)

**COSMATI**, the name bestowed on a Roman family of architects, sculptors and mosaicists, one of whose members bore the Christian name Cosmatus. The activity of this family can be traced through four generations, and opens with the work of Lorenzo, active through the last quarter of the 12th century. His name, with that of his son Jacopo, appears on the portals of the cathedral at Civita Castellana, Sta. Maria di Falleri and the Sacro Speco at Subiaco. The name of Jacopo appears alone on the portals of S. Saba, Rome (1205) and elsewhere, and in association with that of his son Cosmas on the triumphal arch on the façade of

the cathedral at Civit  Castellana (1210). The Cosmas of these inscriptions appears to be identical with a "magister Cosmas," who signed a pavement in the Duomo at Anagni (1231). The names of two sons of Cosmas, Luca and Jacopo, appear in association with that of their father on pavements at Anagni and in the cloister of Sta. Scolastica at Subiaco; and that of Giovanni, a son of Cosmato, is found in Rome on tombs of Sta. Maria sopra Minerva (1296), Sta. Balbina (1303) and Sta. Maria Maggiore. The name of another son of Cosmato, Deodatus, occurs on a pavement in S. Giacomo alla Lungara, Rome, as well as at Teramo (1332) and on a ciborium in Sta. Maria in Cosmedin.

The architectural and decorative style, with its free use of marble inlay and glass mosaic, to which the term Cosmati work has been applied, was not practised solely by this family. Its earliest known exponent was a certain Paulus, who was responsible under Pope Paschal II (d. 1118) for the screen of the Duomo at Ferentino. Other families of Cosmati craftsmen were headed in the mid-12th century by Ranieri and Vassalletto.

Among the most notable of the vast number of works in Rome in the style of the Cosmati are the pavements of S. Clemente and Sta. Maria in Cosmedin, the ambones in S. Lorenzo and Sta. Maria in Aracoeli, and the choir screen in S. Cesareo. The finest of the surviving Cosmati tombs is that of Pope Clement IV (d. 1268) in S. Francesco at Viterbo. This is the work of Pietro di Oderisio, who may in turn have been identical with a "Petrus Romanus" responsible for the shrine of St. Edward the Confessor (1269) and the tomb of King Henry III in Westminster abbey, London.

See E. Hutton, *The Cosmati* (1950).

**COSMETICS AND COSMETOLOGY.** Cosmetics are substances especially prepared to improve, beautify and generally increase the attractiveness of the person. Cosmetic preparations are therefore intended to promote the health and beauty of the complexion, hair, hands and nails. It is the recognition of the dual role of health and beauty that has built cosmetics into a major industry in the U.S. and Britain.

#### HISTORICAL DEVELOPMENT

It is quite probable that cosmetics had their origin in China, but it is necessary to turn to Egypt for the source of the earliest records of cosmetic substances and their application. During the 1st (Thinite) dynasty (c. 3000 B.C.) it was customary to bury comforts and luxuries with the dead kings. Toilet articles and unguents have been found, and in the British museum there are many beautifully carved unguent vases that authorities have dated about 3500 B.C. Other interesting specimens are: *kohl* vases in glass and stibium pencils used in the 18th dynasty 1500 B.C.;

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

papyrus showing men and women having lumps of nard fixed on top of the head (1500 B.C.). The opening by Howard Carter of the tomb of Tutankhamen, who ruled about 1350 B.C., has brought to light many excellent specimens. According to eyewitnesses, the unguent vases contained quantities of aromatics that were still elusively fragrant.

Other monuments and tombs in Egypt still provide ample evidence of the value the ancient Egyptians placed upon cosmetics. For instance, on the large granite tablet inserted in the breast of the Sphinx, King Thutmose IV (c. 1420 B.C.) is portrayed making an offering of incense and of fragrant oil or unguent. At this period it is probable that the priests made most of these compounds, and their manufacture was considered a mysterious and much honoured art. The containers were beautifully executed, principally in ivory and alabaster, while frequently carved wood, onyx and porphyry were fashioned into pots and vases. The ingredients were naturally comparatively simple, limited in both numbers and variety. Among the ingredients grown in Egypt were thyme and origanum, together with a substance called *balanos* that appears to have been extracted from the shells of some unidentified fruit. But the greater proportion of the basic ingredients, such as myrrh, frankincense and spikenard came from Arabia. Sesame oil appears to have been one of the most favoured vehicles for the aromatics, although both almond and olive oils were undoubtedly used.

The ancient Egyptians were probably the first to introduce the bathtub and in later years the bath was treated on a more elaborate scale by the Greeks and Romans. This form of ablution was followed by the liberal application of perfumed oils and unguents

that were found to be soothing and gave the skin a smooth, even colour. Cosmetics were used by Egyptian ladies who enhanced their personal beauty by using somewhat crude paints. Such painting reached its zenith in the time of Cleopatra. As judged from the discoveries in Egyptian tombs and from paintings, the make-up of eyes received the greatest attention. The effects achieved were not unlike some fashions in eye make-up in the 1960s. They were produced by painting the under side of the eye green and the lid, lashes and eyebrows black by the application of *kohl*—the product made from antimony (sulfide) and applied with an ivory or wooden stick. Henna was much favoured for dyeing the fingernails, palms of the hands and soles of the feet. Well-preserved specimens can be seen in the British museum of combs and polished metal mirrors used by Egyptian women. The Bible mentions cosmetics used by Jewish women in II Kings ix, 30, where it is written that "when Jehu was come to Jezreel, Jezebel

heard of it; and she painted her face, and tired her head, and looked out at a window." This is explained more clearly in the following passage: "Thou didst wash thyself, paintedst thine eyes [probably with *kohl*] and deckedst thyself with ornaments" (Ezek. xxiii. 40, and see also Jer. iv. 30). In the Koran aromatics play an important part. The use of eye paint is suggested by *Sura lvi*, "And theirs shall be the Houris with large dark eyes like pearls hidden in their shells."

The Romans, during their early history, showed very little interest in their personal appearance, and it was only after their incursion into southern Italy, then occupied by the Greeks, that they acquired a more intimate knowledge of the aesthetic side of life. By the time Nero became emperor, in A.D. 54, both cosmetics and perfumes had assumed an important role at court. He personally used cosmetics liberally, and his wife, Poppaea, made no secret of using artificial beauty aids. White lead and chalk were used to whiten the skin, Egyptian *kohl* for the eyelids and lashes; *fucus*, a sort of rouge, for the cheeks and lips; *psilotrum*, a species of depilatory; barley-flour and butter as a cure for pimples and skin eruptions; and pumice-stone for whitening the teeth. The ultra-fashionable ladies of the Roman court devised a method for bleaching their hair by means of a soap that came from Gaul. The Romans made many attractive containers for their perfumes and cosmetics. The three principal kinds were: (1) solid unguents or *ledysmata*; (2) liquid unguents or *stymmata*; and (3) powder perfumes or *diapasmata*. The solid unguents were generally of one specific perfume such as almond, rose or quince. The liquid unguents were most frequently compounds of flowers, spices and gums digested in either olive, ben or sesame oil. (Frangipani was invented by a Roman patrician.)

Though the use of cosmetics had long been known in Britain, importation of toilet articles from the east dates from the time of the crusades when returning crusaders brought back many of the cosmetics prized by ladies of the harem. By the reign of Queen Elizabeth I these substances had become more and more popular. The ladies of the court kept their toilet preparations in strongly perfumed boxes called "sweet coffers" that were considered a necessary part of the bedroom furniture. A recipe for making a beautiful complexion at the time of Elizabeth was first to take a very hot bath to induce excessive perspiration and to follow this up by washing the face with plenty of wine, to make it fair and ruddy. This latter treatment was even in those days fairly expensive though Mary Queen of Scots is alleged to have bathed in wine. This luxurious habit was not uncommon with the elder ladies of the court, but the younger ones had to be content with milk. Both sexes used powder and patches and other cosmetics at court. With the advent of the Commonwealth all these luxuries were discarded, but when Charles II was restored to the throne they became popular again. Milk baths were considered an indispensable aid to beauty and in later years the ladies of the court adopted a new practice, probably introduced from France, of powdering their hair, but this soon fell into disuse. By the 18th century cosmetics were used to such an extent by nearly all classes that in 1770, according to G. V. Septimus Piesse in his *Art of Perfumery* (1879), a bill introduced into the English parliament contained the following drastic provision: "That all women of whatever age, rank, profession, or degree, whether virgins, maids, or widows, that shall, from and after such Act, impose upon, seduce, and betray into matrimony, any of His Majesty's subjects, by the scents, paints, cosmetic washes, artificial teeth, false hair, Spanish wool, iron stays, hoops, high heeled shoes, bolstered hips, shall incur the penalty of the law in force against witchcraft and like misdemeanors and that the marriage, upon conviction, shall stand null and void." This same law was adopted by the state of Pennsylvania in the U.S. and the open use of cosmetics was generally looked upon with disfavour in most of the American colonies. Cosmetics were much favoured in Italy and at the court of Louis XIII in France. One of the greatest users was Louis' queen, the beautiful Anne of Austria. From Spain creams of vanilla and cacao and almond paste were imported and used liberally to whiten the skin of the ladies of the court. Louis XIV disapproved of artificial enhancement and consequently cosmetics fell into disuse.

They were again revived under the Regency when the "*poudre à la Maréchale*" was in vogue. The emperor Napoleon I was susceptible to the artistic refinements of his time and the empress Josephine brought from Martinique cosmetics that she always continued to use. The French at this period made a definite move to place the manufacture of perfume and beauty aids upon a scientific basis.

The history of cosmetics in the U.S. stems from Europe and closely parallels its development in Europe. Although the aboriginal Indians used a highly formalized technique of body painting and had knowledge of dyes and pigments, fats and oils, this use of cosmetics never influenced the settlers. During colonial times in the U.S., the use of cosmetics varied enormously in different parts of the country. Puritan New England, for instance, banned it on moral grounds, reflecting the puritanism of the mother country; in the south, especially in colonies of French origin, cosmetics flourished. The conservatism of the Victorian era that frowned upon artificial beauty aids also influenced the cosmetic habits in America. France pioneered in the development and manufacture of cosmetics and French women used make-up long before it was accepted in polite society in England or America. It was not until after World War I that barriers were lowered and prejudices were gradually discarded; even then the use of cosmetics was sporadic and limited as compared with that of the 1960s.

(W. A. Po.; G. R. F.)

## COSMETOLOGY

Cosmetology is a term used in the United States to designate the practice of beauty culture in beauty shops and hairdressing establishments. In the U.S. this industry is limited by law to external treatments for the improvement of the complexion, facial contours, hair, hands and feet. Chiropody and body massage require special licences both in the U.S. and the U.K.

In Britain there are few government regulations affecting the beauty and hairdressing industry. Licences are not required but beauty shops are subject to inspection by local health service authorities. Also, the industry itself lays down certain rules, especially applied to the training of hairdressers through a system of apprentices.

The growth of the modern beauty-shop industry stems from the introduction of the Marcel wave, originated in the 1870s by a French hairdresser, Marcel Grateau. The Marcel waving iron (1897), which was an elaboration of the curling iron women used at home, produced the most natural undulating waves then known and it proved an instant success. As the beauty shop offered more up-to-date and better services its popularity increased, and the practice of hairdressers and manicurists who visited their clients in their homes was gradually replaced by the clients visiting the beauty shop.

An even greater impetus to cosmetology was the introduction in 1906 of the so-called permanent wave, first developed by Charles Nessler, a German coiffeur living in London. The machine was an elaborate contraption that required 10 or 12 hr. for an expensive, tedious and often painful process. Introduced in the United States in 1908, it did not gain a firm foothold until the 1920s when the technique had been improved and hairdressers had become more expert. Although at first resisted by the majority of hairdressers, the vogue for short hair gave permanent waving a tremendous boost. From then on it was left to the manufacturers who supplied the machines and chemicals to improve them and make the technique simpler for both the operator and their customers.

In the 1960s, the permanent wave was the greatest single source of income for the beauty shop, which in the U.S. and Britain includes the hairdresser, the coiffeur or hair stylist. The permanent wave accounted for about 30% of the business in the U.S. and England; cutting, shampooing, tinting and setting the hair brought in even greater revenue, while other aspects of beauty culture steadily dwindled in proportion. The beauty salons still gave "facials," the massage and contour treatments to help keep the face youthful-looking and to beautify the complexion. Beauty treatment for the hands consisted mainly of the manicure

(see *Manicure Preparations* below) and some salons gave pedicures, the beautifying treatment for feet, as well.

### COSMETIC PREPARATIONS

Cosmetic preparations may be divided into three main categories: (1) creams, lotions and emulsions for the care of the skin and hair; (2) make-up preparations, such as powder, lipstick, rouge and nail lacquer, for beautifying; (3) hygienic or toilet preparations (sometimes called toiletries) for promoting good grooming and fastidiousness, such as deodorants, depilatories and preparations for the bath.

The use of cosmetics had never before been so universal as in the 1960s. In the past a wide gulf existed between the upper classes who were the chief users of cosmetics and the rest of the population. With the rise of the middle classes and an affluent society, this gulf has narrowed so that it no longer exists in Britain and the U.S. though it is still noticeable in countries that are poorer, have a large peasant population or have a lower standard of living. As the lifespan has increased, the need to keep the skin healthy and youthful-looking has grown in importance. Without care, the skin loses its resiliency, is depleted of its natural oils and moisture, and becomes dry, wrinkled and old-looking. Cosmetic creams and lotions are designed to prevent this and make-up is used to enhance the individual, often creating the illusion of beauty when skilfully applied.

The greatest problem of skin care is to keep the skin clean and functioning properly. Modern conditions, especially urban life with its atmospheric dirt, smoke and grime mixed with cosmetics, make thorough cleansing difficult. Although soap is a necessary and efficient cleansing agent, it has the tendency to dry out the skin. Cleansing creams dissolve the grime more gently; lubricating creams replace or supplement the natural oils that have been washed away; and foundation creams protect the skin.

**Skin Care.**—*Cold cream* is the basis for the oily and greasy types of creams to which both the cleansing and lubricating creams belong. A standard formula calls for spermaceti 125 gr., white wax 120 gr., expressed oil of almond 560 gr., sodium borate 5 gr., stronger rose water 190 gr. There are many variations of this formula in which other fats are substituted for spermaceti, and paraffin is used in place of white wax; mineral oil (liquid petrolatum) has mainly replaced almond oil as it is more stable, does not become rancid, and melts at a lower temperature. The variations in formulae change the creams only in detail. The standard cold creams are general purpose creams used for their soothing and softening effect.

*Cleansing creams* may be a simple form of cold cream or even a solidified mineral oil that melts almost at touch. As the name implies their purpose is to remove accumulated grime and make-up from the skin. They do this by penetrating the fine crevices of the skin and gently dissolving foreign particles. *Cleansing lotions* are usually emulsions made of lighter oils held in suspension with varying amounts of water.

*Lubricating creams*, night creams or massage creams are a type of cold cream with the addition of lanolin (wool fat) and its derivatives. Until labelling regulations came into force in the U.S. these creams were usually called "nourishing cream" or "skin food," as they are still called in England. Since the skin, like any other part of the body, can be fed only by assimilating food eaten in the usual way and carried through the blood stream to the tissues, these terms are misnomers and can result in a misunderstanding of the function of the creams. Because they contain lanolin, the best substitute for the natural oils secreted by the skin, these creams help to overcome dryness and with consistent use the skin becomes softer and more pliant. In the 1950s small quantities of vitamins and hormones were introduced in some of these lubricating creams in the hope of rejuvenating the skin. No conclusive scientific evidence had been found by the early 1960s to indicate that these ingredients can be absorbed by the tissues and that they do any good.

*Vanishing or greaseless creams* are used primarily as a protective film on the skin and are so called because they seem to disappear when rubbed into the skin. Originally these creams were

made of stearic acid; ammonium, potassium or sodium stearate, a form of soap; glycerol (glycerin) to help retain water; and a substantial proportion of water. When this cream is applied, the water evaporates and a smooth, non-greasy, almost invisible film of stearic acid remains, making the skin appear smoother. Although all vanishing creams are variations of the soap base, some recent formulae include lanolin and its derivatives, cetyl alcohol and vegetable oils. Small quantities of mineral oil or petrolatum may be included for easier spreading and organic bases like triethanolamine may be added to help modify the soap. Sorbitol or propylene glycol sometimes replaces glycerol. These humectants, or moisturizers, also prevent the cream from caking, flaking or rolling when applied to the skin.

*Foundation creams*, also called powder base or make-up base, are a type of vanishing cream and are used primarily to create a smooth foundation for make-up. They protect the skin and conceal imperfections, while make-up becomes easier to apply and lasts longer. Foundation creams are usually tinted to blend with natural skin tones and some, more deeply coloured, are used to deepen the colour of the complexion. Foundation lotions are emulsified versions of the creams and are used for the same purpose.

*Skin tonics or toning lotions* are primarily perfumed alcohol and water. They are usually used after the removal of make-up with cleansing cream and act as a mild astringent, giving the skin a sensation of freshness.

**Make-up.**—This term, adopted from the theatre, refers to the use of beautifying cosmetics such as rouge, lipstick, powder and eye shadow. Until World War I make-up was considered improper and even immoral. Only face-powder, white, tinted pink (flesh) or cream (rachel) and delicately perfumed, was considered permissible in polite society. Much of the face-powder and other make-up preparations were originally imported from France. But by the early 1920s a revolutionary change had taken place, particularly in the United States, first in the attitude toward make-up and secondly in the enterprising development of the cosmetic business. By 1925 rouge and lipstick were generally used and the influence of film stars gave make-up a tremendous boost. Gradually cosmetics developed into a social necessity as more and more women entered into the business world. At first powder, lipstick and rouge were available only in three shades, light, medium and dark, intended for the blonde, medium and brunette complexions. By the 1960s a vast range of shades was available. The popularity of eye make-up increased tremendously during the 1950s.

*Face powder* is used to give a smooth mat finish to the complexion. It should spread easily, evenly and cling well. The major ingredients are talc, a smooth unctuous mineral powder; kaolin, an absorbent processed china clay; zinc or magnesium stearate to increase bulk, improve adhesion and resist moisture; magnesium carbonate is also used as a bulking agent and perfume carrier. To these are added zinc oxide or titanium dioxide, the white opaque pigments that help hide imperfections, and the coloured pigments of iron oxide, earth pigments and insoluble forms of organic dyes that create the various powder shades. Small amounts of oil and other emollients are often added for adhesion and to stabilize colour. The fine texture of powder depends on the sifting process or "bolting." Some face powders are light and fluffy, giving a translucent effect; some are heavier and more opaque; others have a slightly lustrous sheen.

*Compact or compressed powder* is made by mixing powder with a weak gum solution as a binder and pressing it into cakes. The finished cake is somewhat denser than loose powder but soft enough to be readily picked up by a puff or pad.

*Liquid powder* is suspended in water or in oily and non-oily emulsions similar in composition to skin and hand lotions. It tends to dry the skin but when skilfully applied lasts well.

*Cake make-up* is a dense face powder treated with oil or wax to make it water-repellent, compounded with soap or a synthetic surface active agent and then pressed into cakes. It is applied with a moistened sponge or pad.

*Cream make-up* or *suntan make-up* (see below) is a densely pigmented foundation cream and powder combination used to darken the skin or to make it look like a suntanned complexion.

*Lipsticks* are made of waxes, fats, oils and pigments molded into smooth, creamy sticks. They should be firm enough to resist breaking when handled, and also not so soft that they will smear or melt in warm weather. The pigments used are a combination of skin-staining dyes called bromo acids that are among the non-toxic colours certified as safe for cosmetics. Castor oil is used partly as a solvent for the bromo acids and for its viscosity, which helps the colour to stay on the lips. Polyethylene glycols also help solubility and staining. Mineral oil gives lustre; cocoa butter and lanolin are soothing emollients. Other ingredients include a variety of waxes, such as beeswax and spermaceti, and oils for smooth consistency and hardening. Lipsticks are made by grinding the pigments and combining them with the melted waxes and oils. After being heated, the mixture is poured into molds for hardening.

*Rouge* is used to give colour to the cheeks or complexion. Compact rouge contains talc, kaolin, small amounts of white pigment, concentrated red pigment and a gum solution as a binder. Paste rouge pigments are ground with petrolatum, mineral oil, lanolin and waxes to form a smooth consistency. Rouge colours are made to match lipstick colours.

*Mascara* consists of carbon black, brown iron oxide or ultramarine blue pigment combined with a mild soap, triethanolamine stearate, and mixtures of carnauba wax, beeswax and spermaceti. It is applied to the eyelashes with a wet brush. *Cream tube mascaras* are of similar composition, with additional water to attain the required flowing consistency for use in special applicators. The mascara is a mixture of pigments, waxes and synthetic resin in a volatile solvent. After the solvent evaporates, the mascara on the lashes is highly resistant to water.

*Eye-brow pencils and eyeliners* are a mixture of pigments, petrolatum, lanolin and waxes made into pencil-like sticks or contained in plastic swivels. *Eyeshadow* is a creamy preparation of pigments mixed with petrolatum and lanolin. Special pearly effects are obtained by adding fish scale essence.

*Suntan preparations* are a form of make-up (see *Cream make-up* above) intended to make the complexion look as if it had been exposed to the sun. Some are stains consisting of a compound of dihydroxyacetone; others are a dense cream with ultra-violet ray-resistant properties. Other suntan preparations consisting mainly of light oils are used to prevent harmful sunburn when the skin is exposed to the direct rays of the sun for any length of time and to acquire an even suntan. Heavy pigmented preparations keep all active light away from the skin like a parasol and provide complete protection from both tanning and burning. Derivatives of salicylic, anthranilic and para-aminobenzoic acids in thin layers absorb the burning rays. The compounds are incorporated in oil, an alcoholic solution or an emulsified cream that may include a silicone to increase water resistance.

**Hair Preparations.**—The care of the hair has always been considered one of the greatest beauty problems. Hair is harder to keep clean than the face or any other part of the body, and dressing the hair in the prevailing fashion takes more time and dexterity than most women have. Like cosmetics, hair preparations may be divided into three groups: (1) the shampoos and tonics that keep hair and scalp clean and healthy; (2) lotions that make dressing the hair easier; (3) hair cosmetics that improve or change the appearance of hair.

*Shampoos* are based on soaps or synthetic (soapless) detergents; ideally they lather well and cleanse both hair and scalp. Soap shampoos, usually in liquid form, contain large proportions of coconut oil, which produces a heavy lather and is soluble enough to form concentrated solutions. Soaps have the advantage that they do not remove all the natural oil from the hair. Their disadvantage is that they react with the calcium and magnesium salts in hard water and form sticky curds that dull the hair. This deposit may be removed by rinsing with dilute acid solution, vinegar or lemon juice.

Synthetic detergent shampoos may be liquid, powder, paste or cream, all made with sulfonate salts that lather profusely in hard or soft water without leaving a lime compound deposit. These preparations are oil soluble and completely degrease the hair,

leaving it dry and brittle. This disadvantage may be overcome by including a lanolin derivative in the detergent. Surfactants of the alkylolamide class may also be used.

*Dry shampoos* consist of infusorial (diatomaceous) earth or colloidal kaolin. When these powders are dusted into the hair and then brushed out, they carry along excess hair oil and dirt that they have absorbed.

*Hair rinses and conditioners*, which contain cationic surfactants that are attracted to and adhere to the hair, leave an extremely thin oily film; the film makes the hair easier to handle.

*Hair bleaches* consist of hydrogen peroxide solutions or creams usually activated before use by the addition of ammonia. Treatment of hair can be extended until virtually all colour has been removed. Extensive and continued bleaching will cause hair deterioration, which may be counteracted to a considerable extent by rinsing with diluted vinegar solution after each bleach treatment.

*Permanent hair dyes* are based upon paraphenylenediamine or paratolylenediamine. These compounds partially penetrate the hair shaft and form insoluble brown dyes when oxidized by air or with hydrogen peroxide. A wider range of shades is possible when these diamines are used in combination with organic dye intermediates. These intermediates interact during oxidation and can produce colours ranging from yellow through red and brown to black.

*Hair tints*, sometimes included in shampoos, contain water-soluble synthetic dyes and are produced in a wide range of colours. It depends on the type of dye and the method used in application as to the length of time the colour lasts.

*Permanent waving solutions* have evolved from the original ammonia preparations that required an elaborate mechanical arrangement for applying heat. The first process was followed by machineless heating pads that generated heat when moistened. Both of these techniques could be used only by the professional hairdresser. Not until the modern cold process was developed was it possible to do permanent waving in the home. The hair is wound on rods and moistened with a waving solution that first softens the hair. It is then saturated with the waving lotion and the waving action takes place either by a mild chemical oxidizing agent or by the action of air. A hardening agent consisting of thioglycolic acid made slightly alkaline with ammonia or similar mild bases is then applied.

*Wave setting lotions* are of two types. The dilute gum solutions make the hair easier to set and to keep in place. They consist of the natural gums karaya or tragacanth or synthetic resins in water with a certain proportion of alcohol to accelerate evaporation and of humectant to prevent flaking. The other form is the aerosol spray used after the hair is set. It is a modified shellac or a synthetic resin such as polyvinylpyrrolidone (PVP), which is sprayed uniformly on the hair and dries with extreme rapidity.

*Hair lotions* are used for grooming the hair and giving it sheen. They are often called brilliantine, a name long in use, and consist mainly of perfumed mineral oil or petrolatum. Some hair lotions are simple oily liquid emulsions or oily creams of castor oil, mineral oil or a synthetic oil in alcohol.

**Hand Preparations.**—Hand lotions of the classic glycerine and rose water type have been in use since the beginning of the 19th century. Sometimes witch hazel is added and, if a mild bleaching is desired, a small quantity of hydrogen peroxide or lemon juice is included.

*Hand lotions and creams* are based on the vanishing cream formulae. Glycerol is added as a humectant and skin softener, while quince seed mucilage stabilizes the mixture and gives the skin a silky feel. Glycerol monostearate or propylene glycol monostearate are also similar to vanishing cream but contain a higher proportion of water. Beginning in the 1950s, silicones were included in some preparations as an added protection; they are referred to as barrier creams.

**Manicure Preparations.**—Special care of the fingernails began in about 1900. Until nail lacquers were introduced, the manicure consisted of filing the ends of the nails into an oval shape, pushing back the cuticle, then buffing the nails to a high lustre with a

chamois-covered buffer and a polishing power of stannic oxide with chalk and a little jeweler's rouge. The changes in fashion include the use of bright colours on nails to match other make-up. A great deal more attention is paid in the United States to hands and fingernails than in any other country including Britain.

*Nail lacquers* in plain, transparent tints were first introduced as an easier way to give the nails a high polish. The chief ingredient is nitrocellulose, which is made flexible by the inclusion of plasticizers, more durable and lustrous by adding natural and synthetic resins, and more adherent by including gums. White titanium dioxide makes the lacquer opaque; pigments are added that harmonize with lipstick colours.

*Polish remover* consists of acetone or ethyl acetate and sometimes contains a small proportion of vegetable oil or lanolin.

*Cuticle cream and oil* consist of castor and mineral oils with glycerin. Sodium lauryl is sometimes added along with a mild antiseptic. These preparations are used to keep the cuticle soft and pliant. *Cuticle cream* is usually a combination of petrolatum, glycerin and gelatin.

*Cuticle remover* is usually a weak solution of potassium hydroxide that softens the cuticle and makes it easy to remove the dead skin that forms around the nail. This chemical actually dissolves dead tissue and should be rinsed off to avoid damage to live tissue.

**Hygienic or Toilet Preparations.**—*Bath preparations* other than soap include bath salts, bath oil, bubble bath, and talc or dusting powder. *Bath salts* are coloured and perfumed crystals that soften hard water, i.e., they precipitate calcium salts and prevent the formation of curds of lime (calcium). These salts are based upon sodium carbonate decahydrate (sal soda) or sodium sesquicarbonate mixed with coloured and perfumed alcoholic solution. Rock salts are ineffective for water softening.

*Bath oils* are used mainly for their scent. The perfume is dissolved in a low-viscosity mineral oil or synthetic oil such as isopropyl myristate or palmitate. Another type, usually of a polyoxyethylene sorbitan monolaurate, produces a dispersion of extremely fine droplets that perfume the atmosphere.

*Bubble baths* are solid or liquid mixtures of perfumed high-foaming detergent. Among these foaming detergents are the alkylolamides, sulfated fatty alcohols, or sulfated fatty acid glycerides. The stable foam is usually almost immediately broken by the toilet soap used in the bath.

*Bath powder and dusting powder* usually consist of perfumed talc with a moderate proportion of absorbent kaolin.

**Deodorants and Perspiration Checks.**—Deodorants are used to neutralize perspiration odour. Colognes and toilet waters are mild forms; more effective are pastes and creams of antibacterial compounds, such as hexachlorophene and bithionol; antibiotics are sometimes added. Deodorant sticks are perfumed alcohol solidified to a translucent gel by a small proportion of sodium stearate. Perspiration checks and antiperspirants are also made in liquid or cream form. These consist of aluminum salt, a strong astringent that coagulates proteins, destroys bacteria and by constricting the pores reduces perspiration secretion.

*Depilatories* are used to remove unwanted hair, particularly from the arms and legs and from under the arms. Chemical depilatories loosen and soften the hair, which is then washed away. The depilatory creams made with strontium or related sulfides are effective but the strong odour of hydrogen sulfide (resembling rotten eggs) makes them objectionable. A more modern formula based on calcium thioglycolate has a milder odour than can be masked by certain perfumes. Depilatory or epilating waxes are based on rosin and wax mixtures. They are heated gently until melted and applied to the hairy area. The wax is allowed to cool and harden and then is pulled off; the hair comes off with it.

**Preparations for Men.**—*Shaving creams* are of the lathering or nonlathering types; they wet and soften the beard and keep individual hairs upright, making it easier to cut them with the razor.

*Brushless shaving creams* are based on the vanishing cream formula, often with a small amount of added synthetic wetting agent and additional humectant.

*Lather shave cakes and sticks* are good-quality toilet soaps

with alkali at a minimum to reduce skin irritation. Lather creams are softer soaps, with some of the sodium soap replaced by soft potassium soap and more water left in the preparation. Fats and fatty acids used in the preparation of lather shave creams are quick-lathering soaps with dense, moist and lasting lather.

*Aerosol shaves* are correctly called pressure packs since gas under pressure expels foam, not a spray. They are formulated from soap solutions based upon mixtures of triethanolamine and fatty acids; the mixture may be expelled by a compressed gas or low-boiling liquid. Activation of the valve expels the soap and propellant mixture; expansion of the propellant at atmospheric pressure produces the lather.

*After-shave lotions* contain alcohol, water, perfume, astringent and, occasionally, an antiseptic. They feel refreshing and are mildly styptic.

*Pre-shave lotions*, for application before using an electric razor, are alcoholic solutions that leave a trace of oily film on the skin. Some are mildly astringent solutions that tend to tighten the skin and keep individual hairs erect in the path of the razor.

(X.; G. R. F.)

**COSMICAL PHYSICS.** In ancient astronomy, the word cosmical means "occurring at sunrise," and designates especially the rising or setting of the stars at that time. Cosmical physics is a term broadly applied to the totality of those branches of science which treat the phenomena of the cosmos (or universe) and their explanation by the laws of physics. It includes geomagnetism, seismology, the tides, meteorology as related to cosmical causes, the aurora, meteoric phenomena and the physical constitution of the heavenly bodies generally.

**COSMIC RAYS.** The term "cosmic rays" refers both to primary and to secondary cosmic rays. Primary cosmic rays are submicroscopic, electrically charged particles—largely protons—that travel in space at speeds nearly equal to that of light. Some of them happen to approach the earth where, high in the atmosphere, they collide with atoms in the air, giving part of their energy to electromagnetic radiation (photons) and to other particles which proceed in nearly the same direction as the primaries. These new particles and photons are called secondary cosmic rays. Like the primaries, they too may interact with atoms in the air, or eventually with atoms in the earth, until ultimately the energy is converted into heat. The primary and secondary rays are not always distinguishable from each other. As will be explained in the final section of this article, scientists are convinced that there are in the primary rays an appreciable number of neutral (uncharged) particles, in addition to the charged particles.

Though much remains unknown, many things have been learned about cosmic radiation. It is possible to state what kinds of particles comprise the primary rays, to ascertain their density in the space around the earth and to specify their distribution in energy. Scientists can give a fairly complete description of what happens when the primary rays interact with the atmosphere; the kinds and numbers of secondary particles that are produced, and how these secondaries in turn behave until they are finally absorbed. From the radioactivity caused by the cosmic rays, it can even be calculated how intense they were in the distant past. Moreover, one of the sources of cosmic rays has been definitely identified; namely, the sun. But as to the detailed mechanism by which the sun generates cosmic rays, theories and experimental information are incomplete. Furthermore, it is clear that the primary particles of high energy—almost all of those producing detectable effects at sea level—come from beyond the solar system. The exact sources of these particles remain in doubt, although indirect evidence lends strong support to certain hypotheses that are explained in this article.

The presentation of topics in this article is as follows:

#### I. History

1. Discovery of Cosmic Rays
2. First Decade of Analysis
3. Post-World War II Developments

#### II. Methods of Detection

1. Counters
2. Nuclear Emulsions
3. Cloud Chambers

## III. Nature and Origin of Primary Rays

1. Geomagnetic Effects
2. Composition of Primaries
  - Chemical Elements Present
  - Absence of Antimatter
3. Solar Flares
4. Other Time Variations Caused by the Sun
5. Crab Nebula; Synchrotron Radiation
6. Other Supernova Remnants
7. "Unusual" Stars
8. The Jet in Galaxy M87
9. Galactic Magnetic Fields
10. The Galactic Halo
11. Extragalactic Sources
12. Isotropy and Upper Energy Limit

## IV. Particles Discovered in Secondary Rays

1. Positrons
2.  $\mu$  Mesons
3.  $\pi^+$  Mesons
4.  $\pi^0$  Mesons

## V. Transitions in the Atmosphere

1. Fate of Heavy Primaries
2. Interactions of Primary Protons
3. Absorption of Evaporation Products
4. Interactions of Secondary Nucleons
5. Fate of  $\pi^+$  Mesons
6. Fate of  $\mu$  Mesons
7. Fate of  $\pi^0$  Mesons; Cascade Showers
8. Soft and Hard Components
9. Transition Curves
10. N-component
11. Extensive Air Showers

## VI. Importance of Cosmic Rays

1. Exploring the Distant
2. Exploring the Tiny
3. Tracing the Past
4. Cosmological Effects

## VII. Undiscovered Primary Components

1. Evidence of Neutral Components
2. Predictions of Intensity
3. Problems of Detection

## I. HISTORY

**1. Discovery of Cosmic Rays.**—Although cosmic rays are an ancient phenomenon, their effects went unrecognized until 1900–03, when ionization and electrical conduction in gases first came under close scrutiny. It was found that a sample of air in a closed vessel always exhibited a small electrical conductivity in spite of every precaution to eliminate radiation and to prevent leakage along the insulators. The conductivity was observed to increase in proportion to the pressure of the enclosed air, and to be diminished by surrounding the vessel with thick shields; therefore it seemed to be due to some kind of radiation continually entering the vessel through the walls. If so, this was a more penetrating radiation than had ever been known before.

The observation that ionization occurred not only over the land but over the sea, where radioactivity is negligible, suggested that natural radioactivity could not account for the whole effect; but it required daring balloon flights to demonstrate positively the existence of radiation coming from high in the atmosphere or outside it. In 1911–12, V. F. Hess made balloon ascensions as high as 5,000 m. He discovered that below about 700 m. the ionization decreased with altitude, indicating sources on the earth, but that above 700 m. the ionization increased steadily with elevation, being several times greater at 5,000 m. than at sea level. Hess also demonstrated that the ionization was the same night and day, and was therefore not due to rays coming directly from the sun. He concluded that the radiation observed at high elevations was of cosmic origin, and inferred by extrapolating to lower elevations an accurate value of the cosmic-ray ionization at sea level. In 1913 his results were confirmed by W. Kolhörster and extended to an elevation of 9,000 m., where the ionization rate was 12 times greater than at sea level.

The possibility that the radiation originated in the atmosphere was not fully eliminated, however, until R. A. Millikan and collaborators in 1922–26 showed that the air acted only as an absorber and not as a producer of the radiation. They demonstrated this by proving that the rates of ionization at different depths in high-altitude lakes were the same as at lower elevations under equivalent weights of air instead of water.

Until then, cosmic rays were considered to be exclusively gamma rays (*i.e.*, electromagnetic radiation of exceptionally short wave length) because of their penetrating power, which greatly exceeded that of the known charged rays emitted by radioactive substances. However, in 1927 D. Skobel'tzyn observed in a cloud chamber some vertically directed tracks of charged particles so energetic that they were not noticeably deflected by his applied magnetic field, and he pointed out that the frequency of such particles was sufficient to account for the cosmic-ray ionization. Furthermore, in the same year J. Clay discovered the latitude effect; *i.e.*, that cosmic rays are less frequent near the equator than at high latitudes.

In 1929 W. Bothe and W. Kolhörster introduced the technique of employing Geiger-Müller counters in coincidence and proved, by the efficiency with which coincident discharges in the counters were obtained, that many of the observed cosmic rays were indeed charged particles. Climaxing this observation, they interpreted the latitude effect to be a consequence of the primary cosmic rays also being charged particles, and therefore being deflected by the lines of force of the earth's magnetic field as they approached the earth from outer space.

With the explanation of the latitude effect, the existence of charged particles of great energy approaching the earth from distances beyond the sun had become irrefutable. The discovery of the phenomenon of cosmic rays may be said to have been completed at that time, and the era of analysis of the phenomenon had begun.

**2. First Decade of Analysis.**—In the 1930s a world-wide survey of cosmic rays was carried out, both at ground level and with instruments transported in balloons. The intensities found at different latitudes and longitudes were compared with an analysis of the effects of the earth's magnetic field on incoming charged particles, and it was concluded that the primary radiation is composed in the main of positively charged particles, having an average energy of about 10 Bev (billion electron volts). (An electron volt, or ev, is the energy an electron or proton would be given by acceleration through a potential difference of one volt:  $1.6 \times 10^{-12}$  ergs,  $1.6 \times 10^{-10}$  joules or  $1.18 \times 10^{-10}$  foot-pounds. The units kev, Mev and Bev represent  $10^3$ ,  $10^6$  and  $10^9$  ev, respectively.)

The natural occurrence of such particles stimulated both theoretical and experimental investigations into the behaviour of elementary particles at very high energies. In the 1930s cascade showers were discovered, in which a single photon or electron of high energy generates a large progeny of secondary photons, electrons and positrons, the latter being elementary particles equal in mass to the electron but bearing a positive charge. P. Auger discovered extensive showers of particles in the air, indicating the arrival on the top of the atmosphere of single cosmic rays with energies of millions of Bev.

It was found that the secondary cosmic rays near sea level were divided into at least two components: a "soft" component, almost entirely absorbed in 10 cm. of lead, and a "hard" component that could penetrate far underground. The former was identified with electrons, and the latter was found to be comprised mainly of a new kind of particle, now called the mu ( $\mu$ ) meson (see *Particles Discovered in Secondary Rays*, below).

**3. Post-World War II Developments.**—During World War II, as in World War I, cosmic-ray research remained at a standstill. The first decade following the war was marked by rapid development of new experimental techniques and instrumentation: new types of counters, improved electronic devices, sensitive photographic emulsions, more refined cloud chambers and balloons capable of carrying heavier apparatus to higher altitudes. Both the importance and the qualitative nature of nuclear interactions in cosmic radiation were revealed. It was found that in addition to the electromagnetic cascade process, there is a more fundamental nuclear cascade, in the course of which the particles that start the electronic cascades (or electromagnetic cascade showers) are born. The particles that constitute the primary radiation falling on the top of the atmosphere were identified as protons and other atomic nuclei. And many new unstable particles were dis-

covered among the secondary rays.

Methods of radiochemical analysis were also developed, by which minute amounts of radioactivity created by the cosmic rays on the earth, in the ocean, in the air and in meteorites can be used to trace the course of both recent and ancient history.

The extension of radio techniques in this decade led to the discovery of cosmic radio signals coming from both interstellar gases and localized astronomical sources. The new field of radio astronomy (*q.v.*) grew rapidly, and the strong sources of radio noise were correlated with unusual galaxies and supernovae observed in optical telescopes. In 1953-55 it was established that the process responsible for most of the radio waves and much of the light from these objects is synchrotron radiation (*i.e.*, radiation emitted by high-velocity electrons in a magnetic field), indicating an intense flux of particles of cosmic-ray energy in those sources. Thus, a connection was established between optical astronomy, radio astronomy and the source of cosmic rays.

A new era was opened up in Oct. 1957 with the launching of the first artificial earth satellite, sputnik I: the era of direct exploration of space. With the aid of data recorded in rockets, satellites and space probes, relations between many diverse phenomena began to be apparent: comet tails, geomagnetic disturbances, the aurora borealis, the Van Allen radiation belts (*q.v.*), changes in radio-wave transmission and in the reception of cosmic radio noise, and variations in the intensity of primary cosmic rays. See INTERNATIONAL GEOPHYSICAL YEAR; SPACE EXPLORATION.

## II. METHODS OF DETECTION

Until 1928 cosmic rays were detected almost exclusively with electrometers or ionization chambers, which measured only the average ionization current in a gas between an insulated electrode and the wall of a vessel. Since the currents were extremely small (on the order of  $10^{-14}$  amp.) these instruments had to be very sensitive; but they were incapable of detecting and counting individual cosmic rays, or of distinguishing between the types of particles or radiation that might be causing the ionization.

**1. Counters.**—The invention of the Geiger-Müller or G-M counter made great advances possible, since this device can generate detectable electrical signals from single cosmic rays, permitting the times of arrival of individual particles to be measured, and the number of cosmic rays arriving in a fixed time and area to be counted.

G-M counters are limited in two ways: the time resolution cannot be better than about  $10^{-7}$  sec., and the pulse does not indicate the amount of ionization made in the counter by the particle initiating the discharge. Removal of these limitations would help in identifying the particles and measuring their energies. Two kinds of detectors that satisfy these needs were developed by the mid-1950s. Both use a photosensitive electron tube called a photomultiplier (or multiplier phototube) to detect small amounts of visible light caused by the passage of charged cosmic rays through matter. In one kind, the light is produced in special materials that scintillate (*i.e.*, emit characteristic radiation in all directions when their atoms are excited by the passing particle). In the other, the light detected is "Cerenkov radiation" (*q.v.*), which is emitted in a fixed direction and is analogous to the bow wave of a boat moving through water. It is less intense than scintillations, but can be produced in any transparent substance. Both kinds of light are very weak, making sensitive amplifiers necessary; but the amounts of light caused by the cosmic rays depend in a known way on their velocities and charge, permitting these to be measured. The achievable time resolution is about  $10^{-9}$  sec., 100 times better than can be obtained with G-M counters. (See ELECTRON TUBE: Photoelectric Devices; NUCLEAR INSTRUMENTS.)

**2. Nuclear Emulsions.**—The most fruitful information about cosmic rays came, however, not from the above instruments that can resolve small time intervals, but from two other techniques which display the tracks of cosmic rays graphically, showing in detail what occurs in small regions of space. One method is the use of supersensitive photographic emulsions called nuclear emulsions; the older device is the cloud chamber.

Charged cosmic rays passing through emulsions cause ionization in some of the grains and make them developable. If an emulsion is sufficiently sensitive, a single cosmic ray makes enough developed grains so that under microscopic examination they form a well-defined track. Sometimes a cosmic ray undergoes a violent interaction with a nucleus in the emulsion, in which case several tracks are seen radiating from a common point. Such patterns are called "nuclear stars." On other occasions a track may come to an end as a cosmic-ray particle is slowed down in the emulsion, and then the particle may decay, giving rise to a new, lighter and faster particle.

The tracks found in a nuclear emulsion differ from each other systematically in regard to certain features which depend in known ways on the charge, mass and energy of the cosmic rays that produced the tracks. One of these features is the range or residual length of a track, which is observable if the particle stops in the emulsion. For particles having a given charge and velocity, the range is proportional to their mass. Another feature is the grain density  $g$ , or number of developed grains per unit length along the track. This is approximately proportional to  $Z^2/v^2$ , where  $Z$  is the charge of the particle and  $v$  its velocity. When  $g$  is too high the grains merge and cannot be counted; but if this merging is caused by a large value of the charge  $Z$ , numerous "delta rays" (characterized by knobs and short curly tracks) will be seen emanating from the main track. These delta rays consist of electrons with unusually high speeds that have been knocked out of atoms. The number of delta rays, like  $g$ , is approximately proportional to  $Z^2/v^2$ . Finally, the scattering, or erratic changes of direction of the track, can also be measured. The average deviation per unit length is proportional to  $Z/pv$ ,  $p$  being the momentum of the particle.

It follows that two tracks made by particles of different charge or mass can be alike in any one of the measurable properties just described, provided the velocities of the particles are in the proper ratio; but in such cases the tracks will differ in regard to some other property. Thus, identification or mass determination requires measuring two or more of the distinctive features of a track.

With this method, and also by observations of the decay schemes (*i.e.*, characteristic particle transformations and release of energy) of cosmic rays that suffer radioactive decay in the emulsions, several kinds of elementary particles were discovered (see *Particles Discovered in Secondary Rays*, below). Furthermore, analysis of the tracks produced in emulsions carried by balloons near the top of the atmosphere permitted a direct determination of the composition of primary cosmic rays.

**3. Cloud Chambers.**—Cloud chambers (*q.v.*) differ from emulsions in that the tracks are produced in a gas and are visible to the naked eye. The function of the apparatus is to generate a controlled supersaturation of vapour in a closed container. General condensation is prevented because surface tension makes the microscopic droplets evaporate as fast as they are formed. The charged ions produced along the track of a cosmic ray, however, form centres about which drops can grow to a size sufficiently large to scatter enough light to be seen or photographed.

About as many new types of elementary particles have been discovered with cloud chambers as with nuclear emulsions. An equally important accomplishment of both tools of research, however, has been the clear demonstration of electromagnetic and nuclear interactions of the cosmic rays with matter: cascade showers, nuclear disintegrations and the multiple production of mesons. Interesting photographs of these phenomena and further clarification of the methods of identifying the tracks are contained in the books by G. D. Rochester and J. G. Wilson and by C. F. Powell, P. H. Fowler and D. H. Perkins listed in the bibliography.

## III. NATURE AND ORIGIN OF PRIMARY RAYS

**1. Geomagnetic Effects.**—The first information about the nature of primary cosmic rays was derived from the effect of the earth's magnetism on the cosmic-ray intensity. Lines of force of the earth's magnetic field extend many thousands of miles into space around the earth, and charged particles are deflected in crossing these lines of force. Although the intensity of the field

is weak, its great extension accounts for a considerable effect on most of the cosmic rays. Particles with low kinetic energy are turned back and cannot reach the earth at all, while particles with sufficiently high kinetic energy are admitted in changed directions, but with as much intensity as if the field were not there. Particles of extremely low kinetic energy, except those of solar origin, are apparently excluded from the neighbourhood of the earth by interplanetary magnetic fields and by the solar wind, the latter being a stream of gas of solar origin that is caused by eruptions on the sun's surface.

The kinetic energy spectrum of arriving particles extends from about  $10^8$  ev to beyond  $10^{19}$  ev, the number per steradian of solid angle having total energy per nucleon (including rest energy) exceeding  $E$  Bev being fairly well represented in quiet solar periods by

$$0.5 E^{-2.8 + 0.006 \log E} \text{ per square centimetre per second}$$

The number of lines of force which must be crossed varies with the latitude. Even auroral particles can spiral in along the lines of force near the geomagnetic poles; but with decreasing latitude more and more lines of force must be crossed, and hence more energy is required. For protons in the vertical direction, the minimum kinetic energy is 0.4 Bev at geomagnetic lat.  $60^\circ$ , 4 Bev at  $41^\circ$  and 14 Bev at the equator. Measurements near the top of the atmosphere at these latitudes yield counting rates in the ratio 10 to 3 to 1, the rate at geomagnetic lat.  $41^\circ$  (including all directions) being 1 per square centimetre every four seconds.

At high latitudes, the total number of particles crossing unit area at the top of the atmosphere is about 1 per square centimetre every second in quiet periods of the sun. At the equator the number is about three per square centimetre per minute. The number of primary particles decreases rapidly with energy, and particles above  $10^{19}$  ev in energy arrive at the very low rate of about 2 per square kilometre per year.

The cosmic rays of primary energy above 4 Bev are the ones that produce secondaries capable of reaching sea level. The number of secondary charged cosmic rays at sea level is about 1 per square centimetre per minute.

The latitude effect was originally discovered at sea level, but it is much smaller there than at high altitudes; at sea level there is only 8% increase between the equator and geomagnetic lat.  $40^\circ$ , with no further change beyond  $40^\circ$ . This absence of change is due to the fact that the particles with low enough momentum to be admitted only at high latitudes cannot produce secondaries energetic enough to penetrate through the atmosphere to sea level.

There is also an east-west effect. Positively charged primaries must cross more lines of force to arrive from an easterly direction than from the west, while the reverse applies to negatively charged primaries. Measurements show that more particles arrive from the west than from the east, and therefore that most if not all of the primary cosmic rays are positively charged. (See GEOMAGNETISM.)

**2. Composition of Primaries.**—Direct experiments have been performed to determine whether the primaries include electrons and positrons, and whether or not energetic photons comprise a small portion of the primary radiation. In one of these experiments, a cloud chamber was carried by a balloon near to the top of the atmosphere, with lead plates in the chamber so that electrons, positrons and photons could be recognized by cascade shower production. It was found that these components, if present at all, comprise less than 0.5% of the primaries of more than 1 Bev energy. (Ultimately, in 1961 a primary electron component of weak intensity was discovered, amounting to about 3% of the primary particles with energy above  $10^8$  ev, but including very few electrons above one Bev. Also in 1961, a satellite experiment detected a very small flux of primary gamma rays, on the order of 0.03% of the number of charged primaries.)

With neutral particles, photons, positrons and electrons ruled out as major components, and with the fact that the primaries were known to be both stable and positively charged, the most likely conclusion was that they were protons (the nuclei of hydrogen atoms) and possibly nuclei of heavier atoms. This was indeed the case. The most conclusive evidence came from the tracks seen in

nuclear emulsions exposed near the top of the atmosphere. Most of the tracks showed by their grain density that the particles were singly charged; range and scattering measurements identified the mass as that of protons. About one-eighth of the primaries produced denser tracks indicative of alpha particles (helium nuclei, with nuclear charge,  $Z$ , of 2), and 1.6% were indicated to be nuclei of heavier atoms, ranging from lithium ( $Z = 3$ ) to iron ( $Z = 26$ ). No elements heavier than iron had been detected by 1961.

**Chemical Elements Present.**—Studies of meteorites, stellar spectra and the constitution of the earth have led to estimates of the relative abundance of the various elements in the universe. Although there is an approximate similarity with the composition of cosmic rays, if the elements in cosmic rays are compared at equal magnetic rigidity (equal ratio of momentum to nuclear charge), there are a number of highly significant differences. First, the elements lithium ( $Z = 3$ ), beryllium ( $Z = 4$ ) and boron ( $Z = 5$ ) are much more abundant in cosmic rays than in the stars. To account for this, it must be assumed that the heavier nuclei have traveled long enough in interstellar space for some of them to suffer nuclear collisions, with consequent fragmentation into the light nuclei. Second, carbon is more abundant than oxygen in cosmic rays, but six times less abundant in the universe. This suggests that the major cosmic-ray production occurs in stars having conditions of temperature and pressure that lead to exceptional production of carbon. Third, all the heavy elements are more abundant relative to hydrogen in cosmic rays than in the universe, the discrepancy increasing from a factor of 2 to 50 with increasing  $Z$  from helium to iron. Since the cosmic rays have undergone some fragmentation in space, the discrepancy must be even greater at the source.

Therefore, the sources of high-energy cosmic rays must be exceptionally rich in heavy nuclei such as iron. Such composition is characteristic of supernovae. The presence of the lithium, beryllium and boron in the cosmic rays prescribes a lower limit to the average amount of matter traversed after the cosmic rays were produced, and the residue of iron and chromium prescribes an upper limit. These limits are about 1 and 8 g. per square centimetre for the product of density and distance. The corresponding time in transit is 600,000 to 5,000,000 yr. divided by the number of hydrogen atoms per cubic centimetre in the interstellar space.

**Absence of Antimatter.**—A search has been made among primary cosmic rays for nuclei of antimatter. Antimatter behaves chemically like ordinary matter, but is composed of atoms in which positrons, rather than electrons, revolve about nuclei consisting of antiprotons and antineutrons, rather than protons and neutrons. If ordinary matter and antimatter are brought together they annihilate each other, converting all their mass into energy. From the rarity of such processes in interstellar space, it is known that less than  $10^{-8}$  of the atoms in our galaxy are composed of antiparticles; but the idea of symmetry in creation has encouraged the thought that distant galaxies may be of the opposite type, so that the amounts of matter and antimatter in the universe are equal. This idea has more than an aesthetic basis: the constituents of ordinary atoms can be created and destroyed in the laboratory, but only by processes in which equal numbers of antiparticles are also created and destroyed simultaneously.

It has been found that less than 1 in 1,000, if any, of the primary cosmic rays are antiparticles. Therefore, either the universe is not symmetric or else very few of the cosmic rays have come from distant galaxies.

**3. Solar Flares.**—Since 1933 increasingly numerous stations distributed over the earth have kept continuous records of the cosmic rays. Ordinarily the rates at sea level are quite steady, but on five occasions in the period 1942–60 sharp increases were noted. In ten minutes to one hour, the intensity rose by amounts varying from 15% to 5,000% (the latter enormous increase being recorded on Feb. 23, 1956). During the following day on each occasion the intensity gradually returned to normal.

Each of these events was coincident with an unusually strong solar flare (see SUN). Astronomers noted a sudden increase in

brilliance of a small area on the visible side of the sun where a sunspot group had been developing, and radio telescopes detected an outburst of solar radio noise. Photographs of the edge of the sun showed violent turbulent processes occurring, in which giant streams of matter shot far out into the corona. Radio stations suffered abrupt fade-out of high-frequency transmission, owing to increased ionization of the upper atmosphere produced by abnormal amounts of ultraviolet rays and X-rays from the sun; and low-frequency radio propagation was affected by enhanced ionization farther down in the stratosphere, which was caused by low-energy cosmic rays. About a day later, geophysicists observed sudden changes in the earth's magnetic field due to currents of charged particles near the earth that were caused by arrival of the solar streams.

On these few occasions the creation of high-energy cosmic rays at the sun certainly took place. One of the additional indications that the particles came from the sun was the location of the points of impact. The greatest and most abrupt increases of cosmic-ray intensity occurred in areas that coincided with the calculated regions where cosmic rays coming from the direction of the sun should strike after deflection by the earth's magnetic field.

In 1958 and subsequently, by use of high-altitude balloons, rockets and artificial satellites, and also by study of the reception of cosmic radio noise, it was learned that solar flares which produce fast protons are by no means as rare as the above-mentioned five giant flares detected at sea level. At an average frequency of about one a month, but varying widely in the 11-year sunspot cycle, flares on the visible side of the sun are followed within an hour by intense streams of protons striking the atmosphere at high latitudes; sometimes these protons arrive at hundreds of times the normal cosmic-ray rate, but they are too low in energy per particle to produce secondaries that penetrate to sea level. The solar particles are detectable with counters near the top of the atmosphere, and they can be observed indirectly at sea level in the auroral zone by means of the sudden absorption of cosmic radio noise caused by enhanced ionization in the upper atmosphere.

These events are initiated by explosions below the surface of the sun which cause turbulent hydrodynamic motions that grow into shock waves in the ionized gas of the corona. The rapid changes of magnetic field in these shock waves can accelerate some of the particles in the outer corona to cosmic-ray energies, mainly by electromagnetic induction (*i.e.*, by the fact that a changing magnetic field generates an electric force). A cloud of plasma shoots out from the solar surface, typically at a speed of 1,000 km. per second, with the cosmic rays embedded in it, trapped by the magnetic fields. On some occasions the cosmic-ray particles are energetic enough to escape from the plasma and travel ahead of it toward the earth, but they may still be dissipated by interplanetary magnetic fields. In cases when intense beams of solar cosmic rays succeeded in reaching the earth, the flares had been preceded within a few days by one or more other outbursts of solar plasma, which apparently swept out the normal interplanetary field and left in their wake a field-free region, in which the subsequent flare particles could travel comparatively unimpeded from the sun to the earth. The slower-moving plasma emitted with the flare particles arrived at the earth about a day later, producing a geomagnetic disturbance at that time.

Magnetometers in space vehicles have determined that the quiescent interplanetary magnetic field along the earth's orbit is constant at about 2.7 gammas ( $1 \text{ gamma} = 10^{-5} \text{ gauss}$ ), upon which increases as large as 50  $\gamma$  are superimposed by solar disturbances. In a field as strong as 2.7  $\gamma$ , even the more energetic solar protons (0.1 to 10 Bev) would ordinarily be trapped and would diffuse very slowly to the earth if the field had not been rearranged or removed by a prior solar stream.

Although the sun is the only positively identified source of cosmic rays, it is definitely known that the sun is not the source of all of them. In the first place, the observed flare increases are much too rare. Second, the average energy of the cosmic rays received during the flares is much less than the normal value. Third, the chemical composition is abnormal, helium being virtually absent in the solar-flare particles. Fourth, even cosmic

rays of extremely high energy are ordinarily found to be almost perfectly isotropic; *i.e.*, they arrive equally from all directions in space. If these high-energy particles came from the sun, they could be made isotropic only by being deflected back and forth thousands of times by magnetic fields in the solar system; but for this the existing fields are much too small. The sun may be the source of a significant part of the least energetic cosmic rays, but not of those of high energy. (*See MAGNETOHYDRODYNAMICS.*)

**4. Other Time Variations Caused by the Sun.**—A periodic 11-year cycle has been found in cosmic-ray intensity. The variation observed near sea level at moderate latitudes is only about 5%, but at high latitudes and altitudes, where particles of lower energy can enter, the change between the maximum in 1954 and the minimum in 1958 exceeded a factor of five. The cosmic-ray cycle is related to the 11-year cycle in sunspots, solar coronal activity and geomagnetic disturbance, the intensity being least when the solar activity is greatest. During years of high solar activity there often occurs a cosmic-ray variation that repeats with a 27-day period. This is approximately the period of rotation of the sun, and the cosmic-ray effect proved to be associated with the passage of regions of solar activity through the meridian. The variation is typically several per cent. There is also a very small diurnal variation, much less than 1%, that changes with time in amplitude and phase.

In addition to these periodic variations, a decrease in cosmic-ray intensity called a "Forbush effect" occasionally occurs one or two days after a disturbance on the sun. The effect persists for several days, and is correlated with a geomagnetic storm; *i.e.*, a small change in the earth's field caused by particle emission from the sun. On rare occasions the decrease has been as large as 20%. In 1960 instruments on the space probe Pioneer V detected such a Forbush effect in space, 3,000,000 mi. from earth, while at the same time an equal decrease in cosmic radiation was recorded on earth.

The periodic variations and Forbush decreases are caused by the streams of magnetized plasma referred to above, which are emitted sporadically by the sun in connection with solar flares and travel outward at speeds of about 1,000 km. per second. The density of the magnetic streams in the solar system is greatest in years of high sunspot activity. The streams deflect cosmic rays approaching from interstellar space and prevent some of them, especially those of low energy, from reaching the earth. The fact that the average cosmic-ray intensity is low in disturbed solar periods shows that the sun is ordinarily more effective in keeping cosmic rays away from the earth than in producing them.

In 1960 this explanation was confirmed by direct measurement of the cosmic-ray intensity between the orbits of Earth and Venus. As Pioneer V went closer to the sun, the cosmic-ray intensity went down slightly, as expected in consequence of solar modulation of galactic cosmic rays, instead of going up, as would have occurred if the sun were mainly a producer of the cosmic rays.

**5. Crab Nebula; Synchrotron Radiation.**—In the constellation of Taurus, within the earth's galaxy, there is a nebular object (the Crab nebula) which is apparently the expanding debris of a supernoval explosion recorded by the Chinese in A.D. 1054. Its present brightness is that of 1,000 suns. In the 1950s a remarkable discovery was made concerning this nebula: in addition to unpolarized light of characteristic wave lengths, such as ordinary stars produce, it emits visible light with a continuous spectrum, and this light is strongly polarized. Only one process is known whereby such light can be generated with appreciable efficiency: the acceleration of highly relativistic electrons (*i.e.*, electrons with velocities near that of light) moving in a magnetic field. Such light is seen, for instance, in high-energy electron accelerators called synchrotrons, and has become known as synchrotron radiation.

The Crab nebula is also one of the strongest sources of radio noise in the sky. The strength and spectral distribution of this radiation are consistent with the amount of continuous visible light, if both are attributed to synchrotron radiation from the same source. The hypothesis was substantiated in 1957 by the discovery that the radio waves, like the light waves, are strongly

polarized, and that the directions of polarization of the light and radio waves are consistent with each other.

Synchrotron radiation has a short wave-length limit proportional to  $m^3/BE^2$ , and dissipates energy at a rate proportional to  $B^2E^2/m^4$ , where  $m$  is the mass of the particles,  $E$  their energy and  $B$  the magnetic field strength. Since the light extends at least into the blue colour,  $BE^2$  must extend to at least  $10^{10}$  in units of gauss  $\times$  (ev)<sup>2</sup>. The total energy that has been emitted by the electrons in the form of synchrotron radiation since A.D. 1054 is at least  $10^{48}$  ergs. The present volume of the expanding nebula (the shell of which is moving outward at about 1,100 km. per second) is  $V = 10^{58}$  c.c. The most conservative estimate of total energy in the plasma is obtained by equating the magnetic energy ( $B^2V/8\pi$ ) to that given to the particles. In this case  $B$  is approximately  $10^{-8}$  gauss, and the calculation shows that  $10^{46}$  electrons with energies over 100 Bev have been produced in the supernova.

The region must be electrically neutral on the whole; hence, positively charged nuclei must be as abundant as the electrons. The nuclei would be accelerated more efficiently than the electrons, and to higher energy, since they are too heavy to lose energy by radiating light; they would leak out into the galaxy as cosmic rays. It has been hypothesized that nuclear collisions of these particles are the means by which the supply of high-energy electrons is replenished within the supernova, since the drain on electron energy due to synchrotron radiation makes direct acceleration of the electrons more difficult. If this hypothesis is correct, the energy released by such a supernova in the form of galactic cosmic radiation is over  $10^{50}$  ergs, about 1% of the nuclear energy released in the explosion. The high efficiency of conversion of hydrodynamic energy into relativistic particles was accounted for (in theories proposed in 1960) by the behaviour of shock waves initiated by the explosion. Two mechanisms, both of which seemed capable of high efficiency, were considered in these theories. One is the sweeping up and accelerating of cosmic rays already existing in the interstellar medium around the star. The other is direct acceleration of gas in the mantle of the star by the shock wave.

**6. Other Supernova Remnants.**—Besides the Crab nebula, remnants of five other supernovae can be seen in the visible part of the galaxy: Cassiopeia A, the explosion of which was observed in 369 A.D. and which is still the source of the strongest radio waves reaching the earth from outside the solar system; "Kepler's nova" of 1604; "Tycho's nova" of 1572; and the supernovae of 1006 and 185 A.D. Of these, four are still strong radio sources. It is estimated that on the average, the number of such occurrences in the whole galaxy is about one per 100 yr., providing about  $3 \times 10^{40}$  ergs per second of cosmic radiation. This figure should be compared with the supply rate of  $10^{41}$ – $10^{42}$  ergs per second which is needed to maintain the observed flux of cosmic rays throughout the galaxy. Within the accuracy possible in estimating these figures, they may be considered equal. (See NOVA AND SUPERNOVA.)

**7. "Unusual" Stars.**—Not only supernovae but also red giants and young, active stars of the T Tauri type are suspected of being effective sources of cosmic radiation. The infrequent solar emissions and the analysis of supernovae demonstrate that production of high-energy cosmic rays is not a normal phenomenon in ordinary stars, but occurs at times and places where events of unusual violence are happening.

**8. The Jet in Galaxy M87.**—About 40,000,000 light-years away in the Virgo cluster there is a spherical galaxy designated M87. In it is a segmented jet-like luminosity with dimensions of about 400 by 4,000 light-years, roughly 10,000,000 times as big in volume as the Crab nebula. This jet is not just a star but a sizable part of a galaxy. The whole area emits radio noise and a continuous spectrum of polarized light, like the Crab nebula, but much more intensely, and so is inferred to be a fantastically potent source of cosmic rays.

**9. Galactic Magnetic Fields.**—In view of the discreteness of cosmic-ray sources, the observation that cosmic rays ordinarily approach the earth equally from all directions obviously required an explanation.

In 1949 Enrico Fermi first suggested the probable existence of weak magnetic fields in interstellar space, stirred up and carried about by turbulent clouds of rarefied, highly ionized gas. Astronomers were aware of moving galactic clouds of gas and dust; they later found evidence for the fields by observing that light from distant stars is slightly polarized, as would result from scattering by dust grains magnetized and aligned by a magnetic field.

Fermi proposed that the deflection of cosmic rays by magnetic clouds would not only account for the isotropy of cosmic rays, but also provide a means of storing and accelerating them. Successive reflections would make the particles follow extremely tortuous paths, losing all sense of their initial directions and prolonging their life in the galaxy. Since the clouds are in motion, cosmic rays would gain a little energy on the average in every reflection, just as a ball can gain speed by bouncing off a moving wall.

**10. The Galactic Halo.**—Radio astronomers discovered that the earth's disk-shaped galaxy, as well as other spiral galaxies, is surrounded by a spherical region, about 50,000 light-years in radius, which is a source of radio noise though not of visible light. This noise is evidence of the existence of charges and fields in the spherical halo, and hence of ionized matter, less dense than in the arms of the galaxy but in more rapid motion. The radio noise was identified with synchrotron radiation emitted by electrons of energy  $10^8$ – $10^9$  ev. These electrons are believed to be produced by nuclear collisions of cosmic-ray protons that are trapped in the magnetic field of the halo.

Assuming the cosmic-ray energy density to be the same as near the earth, in the volume of  $0.6 \times 10^{69}$  c.c. the total energy is  $10^{87}$  ergs. The average gas density is believed to be  $10^{-2}$  atoms per cubic centimetre in the halo and 1 per cubic centimetre in the central disk, hence the mean lifetime of the protons before nuclear collisions is  $5 \times 10^{16}$  sec. ( $1.5 \times 10^9$  yr.). Each collision transfers 5%–10% of the energy to electrons through meson production and decay. Therefore the rate of energy transfer to high-energy electrons is computed to be about  $10^{39}$  ergs per second. The observed power in the synchrotron radiation from the galaxy is  $2.5 \times 10^{38}$  ergs per second. Thus the model accounts very well for the measured radiation. This is essentially the same model that was applied above to account for the light and radio waves from supernovae and the galaxy M87. Its quantitative success in explaining phenomena in our own galaxy encourages confidence in this interpretation.

**11. Extragalactic Sources.**—Because of the magnetic fields, cosmic rays from external galaxies have as much difficulty in entering our own galaxy as the local cosmic rays have in escaping. But the abundance of heavy nuclei in cosmic rays implies that the particles can escape from the galaxies in which they are created in times on the order of  $10^8$  yr. Therefore intergalactic space acquires an appreciable flux, and some interchange between galaxies occurs. The expansion of the universe limits the effective time of filling up intergalactic space to about  $2 \times 10^{10}$  yr., and the space is about  $10^4$  times larger than that in the galaxies; hence the cosmic-ray density outside the galaxy is probably less than that inside by a factor of 10 to 100. Therefore, extragalactic sources are probably not as effective in supplying ordinary cosmic rays as are intergalactic sources near the earth. But other galaxies may supply the rare particles of greatest energy, exceeding  $10^{18}$  ev, which are less efficiently contained by galactic fields, and for which there does not appear to be a large enough source in our own galaxy.

**12. Isotropy and Upper Energy Limit.**—There are several reasons for expecting anisotropy in cosmic rays of extremely high energy. The sources of such particles are relatively rare in the universe. Ultimately the magnetic fields in interstellar space should be unable to reflect the particles and so randomize their directions. For instance, in the estimated field strength of  $5 \times 10^{-6}$  gauss the radius of curvature of a  $10^{19}$ —ev proton is 7,000 light-years. If regions of consistent field direction are smaller than this, the particle cannot be reflected. Also, the magnetic fields, gas and cosmic rays are presumably distributed with some nonuniform structure in space, analogous to the distribution

of visible material. When the energy is high enough for the field to change appreciably in one radius of gyration of the particles, preferred directions of motion should be apparent. Thus, the energy at which anisotropy begins to appear should afford a measure of the structure of galactic magnetic fields.

There should also be an upper limit to cosmic-ray energies, because of the finite size and field strength of the sources. When a particle cannot be repeatedly reflected in the magnetic field of the source, the particle escapes and is no longer accelerated. Thus, determination of the upper energy limit should give a measure of the size and energy density of the largest cosmic-ray sources.

Many experiments have sought to detect the anisotropy and upper energy limit of cosmic rays. At  $10^{15}$  ev the isotropy was found to be good to at least 1 part in 1,000; at  $10^{17}$  ev, to at least 10%. The scarcity of particles above  $10^{19}$  ev in energy made it hard to measure their isotropy quantitatively, but the small numbers of observed particles seemed to be random in direction. As for the upper energy limit, the shape of the curve of number of particles per unit area per unit time  $v$ , particle energy as the energy approaches the highest value observed by 1961 (about  $3 \times 10^{19}$  ev) gives no hint that the upper limit is near: the number continues to decrease with energy in the same way as at much lower values.

It is interesting to try to visualize the dimensions of the natural accelerator that is required to produce particles of such fantastic energies. The field strength can hardly exceed  $10^{-2}$  gauss since the gas density must be low. To contain the particles long enough to accelerate them, the dimensions must be at least 100 times the radius of gyration of the particles. Therefore the diameter of the source must be at least 100 times the distance from the earth to the nearest star beyond the sun.

#### IV. PARTICLES DISCOVERED IN SECONDARY RAYS

All known elementary particles are present in secondary cosmic radiation. They are produced by interactions between highly relativistic primaries and nuclei in the air, and by subsequent nuclear interactions or radioactive decay of the initial products. Many of the particles do not occur in nature except when created by cosmic rays, because of instability against radioactive decay and the concentration of energy required to create the masses. They can be produced in laboratories by means of accelerators; however, many of them were first discovered among cosmic rays, because high energies were available in cosmic rays before the accelerators were built, and because of the exploratory rather than selective nature of cosmic-ray experiments.

In this section, brief descriptions will be given of several of the elementary particles which were not known until their discovery among cosmic rays. For more detailed information on these and other elementary particles, see ELECTRON; NEUTRON; PARTICLES, ELEMENTARY; PROTON.

**1. Positrons.**—The positron was discovered in 1932 by C. D. Anderson, who used a cloud chamber in a strong magnetic field. A positron is the same as an electron except that its charge is positive instead of negative. It is a stable particle in a vacuum, but when it slows down in matter it unites with an electron and they are annihilated, giving rise to two quanta of radiation.

Positrons are often produced in cosmic rays by pair production, the inverse of the annihilation process: a high-energy photon interacts with the electric field of a nucleus (i.e., with virtual photons) and is absorbed, while an electron and a positron are created, sharing the energy of the photon. A second means of production is the decay of positive  $\mu$  mesons, discussed below. Positrons constitute about 10% of the charged cosmic rays at sea level, and 20% to 30% at mountain or airplane altitudes; they are almost as numerous as the electrons.

**2.  $\mu$  Mesons.**—Positive and negative  $\mu$  mesons were discovered during the years 1933–38 by the combined weight of evidence from many experimenters. They all used cloud chambers with magnetic fields, and measured the momentum of the particle plus an additional parameter (specific ionization, range or shower-producing ability) to establish the approximate mass. The  $\mu$  mesons have the longest ranges of any particles except neutrinos.

That is why they constitute three-fourths of the charged cosmic rays at sea level, and are the only charged cosmic rays that penetrate more than a few metres into the ground. Some of them have been detected after passage through as much as 2 mi. of rock.

It might be expected that  $\mu$  mesons, being unstable with a mean lifetime of  $2.2 \mu$  sec., would all decay in the atmosphere. This actually happens to some of them and accounts for most of the positrons and electrons among the cosmic rays at sea level. Because of relativity, however, time passes more and more slowly for particles of greater and greater energy (see RELATIVITY: *Special Theory of Relativity*). The factor by which the time scale changes, called the Lorentz factor,  $\gamma$ , equals  $1 + E/mc^2$ ; where  $E$  is the kinetic energy of the particle and  $mc^2$  its rest energy (0.106 Bev for  $\mu$  mesons). Thus, particles having a speed  $v$  and mean lifetime  $T$  travel an average distance  $\gamma vT$  before decaying. For  $\mu$  mesons of 3 Bev energy,  $\gamma = 29$ , and the average range before decay is 18 km; this allows many of them to reach sea level even though they are produced at high altitudes.

**3.  $\pi^\pm$  Mesons.**—Positive and negative  $\pi$  mesons were discovered with nuclear emulsions by C. M. G. Lattes, G. P. S. Occhialini and C. F. Powell in 1947. The type of event that led to their discovery was a  $\pi^+$  meson coming to rest in an emulsion and undergoing radioactive decay. Negative  $\pi$  mesons look different from positive ones at the ends of their ranges in emulsions, because  $\pi^-$  mesons are attracted into nuclei before decaying and cause disintegrations of the nuclei. The visible result is a star at the end of the track of each  $\pi^-$  meson. In the air, however, both  $\pi^+$  and  $\pi^-$  mesons decay before being captured. The mean lifetime is  $2.56 \times 10^{-8}$  sec., and the decay products are a  $\mu$  meson and a neutrino.

The mass of  $\pi^\pm$  mesons is 1.32 times that of  $\mu$  mesons. The extra mass is released upon decay as kinetic energy of the new particles. When  $\pi^-$  mesons are absorbed in nuclei, the mass becomes excitation energy and is carried off by nuclear fragments.

The  $\pi^\pm$  mesons are copiously created in cosmic rays by collisions of primary and secondary nucleons (i.e., protons and neutrons) and other  $\pi^\pm$  mesons with nuclei of air; smaller numbers are made by nuclear absorption of photons. They have also been produced artificially by similar encounters in cyclotrons and synchrotrons.

When  $\pi^\pm$  mesons are produced in the air they soon decay, unless their energies are exceptionally high, because of their short mean lifetime. Those that escape decay are mostly absorbed by interacting with nuclei. As a result,  $\pi^\pm$  mesons constitute less than 1% of the charged cosmic rays at sea level. However, their decay is the principal means of creation of  $\mu$  mesons, the major component of sea-level cosmic radiation.

**4.  $\pi^0$  Mesons.**—The neutral  $\pi$  meson was predicted theoretically in 1948, before its experimental discovery; its lifetime was calculated to be very short for decay into two photons, which in turn would create electrons and positrons by pair production. The theory offered a happy solution to two anomalies that had existed in cosmic rays: the great abundance of positrons and electrons at high altitudes in spite of their scarcity in the primary radiation, and the observed origin of positrons and electrons near nuclear interactions in which charged  $\pi$  mesons were created. It was even possible to determine the mass of the  $\pi^0$  meson from the energy spectrum of photons near the top of the atmosphere. However, because  $\pi^0$  mesons exist so briefly and are neutral, they could not be detected directly; conclusive evidence for their reality was not obtained from cosmic rays, but with the Berkeley cyclotron and synchrotron in 1950.

The mass of the  $\pi^0$  meson is about 4% less than that of charged  $\pi$  mesons. Its mean lifetime is about  $2 \times 10^{-16}$  sec., as determined by measuring the microscopic distances from nuclear interactions where  $\pi^0$  mesons are produced to the points where they decay.

#### V. TRANSITIONS IN THE ATMOSPHERE

In this section will be outlined the processes by which the cosmic rays change in composition and in number of particles as they filter through the atmosphere. The facts are pieced together from

observations of individual transformations that take place in cloud chambers and nuclear emulsions, and from measurements of the numbers of cosmic rays of various types as a function of depth in the atmosphere and earth.

Throughout the discussion, the unit  $\text{g./cm.}^2$  (grams per square centimetre) will be used as a measure of the path traversed: a distance in these units equals the length in centimetres times the density in grams per cubic centimetre, and thus measures the weight in grams of a column of the substance one square centimetre in cross section. The thickness of the atmosphere above a point of observation in the vertical direction is  $1,030 \text{ g./cm.}^2$  at sea level, and decreases approximately by a factor of 2 for each 5 km. or 16,000 ft. of elevation, so that at 16 km. or 10 mi. elevation the residual atmosphere is  $100 \text{ g./cm.}^2$ .

The unstable particles heavier than  $\pi$  mesons will be neglected, since they are produced comparatively rarely; and their brief existence, before decaying into the various components which will be discussed in detail, is unimportant to the major transitions in the atmosphere. Antinucleons will be neglected too, because of their infrequent production.

**1. Fate of Heavy Primaries.**—Heavy primary nuclei lose energy by ionization faster than protons in proportion to the square of their charge; hence, most of them are stopped by ionization losses near the top of the atmosphere. The more energetic ones interact with other nuclei and are thereby broken up into protons and neutrons, which behave thereafter like the more numerous primary protons. The larger the nucleus, the shorter the mean path length traversed before breakup; the mean length varies from  $45 \text{ g./cm.}^2$  for alpha particles to  $20 \text{ g./cm.}^2$  for primary silicon nuclei and  $14 \text{ g./cm.}^2$  for iron. This explains why heavy primary nuclei are only detected at very high altitudes, and justifies omitting special mention of them in further discussion of atmospheric transitions.

**2. Interactions of Primary Protons.**—The typical initial interaction of a primary in the atmosphere is the collision of a proton with a nucleus of nitrogen or oxygen. The immediate effects are the following: (1) a number of  $\pi^\pm$  and  $\pi^0$  mesons are produced, in approximate ratio 2 to 1, the total number depending on the primary energy but being typically between 2 and 10; (2) the original proton continues with reduced energy, together with one or two nucleons of the struck nucleus which were given high velocities by the collision; and (3) the residual nucleus is left in an excited state, from which it recovers by emission of slower protons and neutrons in any direction, or by breaking up into deuterons, tritons and alpha particles. These fragments typically have energies on the order of 10 Mev and are called evaporation products.

**3. Absorption of Evaporation Products.**—The progress of each kind of particle emerging from the initial nuclear interaction will now be followed, beginning with the evaporation products. The charged ones ionize heavily and lose their energy in less than  $1 \text{ g./cm.}^2$  of air. The neutrons lose no energy by ionization and travel much farther before absorption, through 5% to 10% (by weight) of the atmosphere. They are gradually slowed down by collisions with atoms of oxygen and nitrogen; and with decreasing velocity, their chance of being captured in a collision increases. Most of them reach energies of about  $\frac{1}{2}$  ev before they are finally captured by a nitrogen nucleus, which then emits a proton and becomes radioactive carbon,  $\text{C}^{14}$ .

**4. Interactions of Secondary Nucleons.**—Secondary nucleons of energy large compared with a Bev, whether they are protons or neutrons, behave like the primary radiation, undergoing nuclear collisions from which further mesons, fast secondary nucleons and evaporation products emerge. This stepwise multiplication of mesons and nucleons through successive nuclear interactions is known as a nuclear cascade. The average distance between steps is about  $\frac{1}{3}$  of the vertical atmosphere by weight, or  $80 \text{ g./cm.}^2$ . How many steps are possible depends on the primary energy; and how far a given cascade proceeds also depends on chance fluctuations of the distance traveled between collisions. Some nuclear cascades are still proceeding vigorously at mountain elevations; but the number decreases rapidly as sea level is ap-

proached, changing by a factor of 2 in every  $82 \text{ g./cm.}^2$ , or by a factor of 13 in the last 10,000 ft.

Secondary nucleons of energy less than 2 Bev usually undergo nuclear interactions that yield only charged nuclear fragments of rather short range, plus neutrons that continue until they make another star in which only evaporation products are emitted.

**5. Fate of  $\pi^\pm$  Mesons.**—Primaries of extreme energy, more than  $10^{13}$  ev, may produce  $\pi^\pm$  mesons of more than  $10^{11}$  ev. For these, the relativistic time dilatation is so great that they may travel long distances, far enough to experience nuclear collisions instead of decaying. The effect of these mesons is like that of the high-energy secondary nucleons: they contribute to the nuclear cascade, producing further  $\pi^\pm$  and  $\pi^0$  mesons and fast secondary nucleons as well as evaporation fragments.

Much more common, however, are  $\pi^\pm$  mesons of less than 100 Bev energy. These usually decay without further interactions and thus give rise to  $\mu^\pm$  mesons and neutrinos. The neutrinos have no observed effect except for the disappearance of energy and momentum which they carry with them.

**6. Fate of  $\mu$  Mesons.**—The  $\mu$  mesons retain about 80% of the energy of the  $\pi^\pm$  mesons, and very seldom lose it by nuclear collisions. Instead, there is a gradual loss of energy by ionization, amounting to about 2 Bev on the average before a  $\mu$  meson reaches sea level, since most of them are produced in the uppermost  $200 \text{ g./cm.}^2$  of the atmosphere.

Many of the  $\mu$  mesons, including a small fraction of those having tens of Bev of energy, decay during flight through the atmosphere. About two-thirds of the energy and momentum is then taken away by neutrinos, but the remainder is given to a high-energy electron or positron, the behaviour of which will be discussed later. Fast  $\mu$  mesons also generate a minor fraction of the high-energy electrons in the atmosphere by occasional close collisions with electrons belonging to atoms in the air. The particles so produced are called "knock-on electrons."

However, most of the  $\mu$  mesons of many Bev energy survive until they reach the ground, and dissipate the remainder of their energy by ionizing atoms along their paths into the earth. The rate of energy loss is about 2.2 Mev per  $\text{g./cm.}^2$ , and the density of the earth's surface is about  $2.7 \text{ g./cm.}^3$ ; hence a meson of 20 Bev, for instance, penetrates 110 ft. before coming to rest.

**7. Fate of  $\pi^0$  Mesons; Cascade Showers.**—The  $\pi^0$  mesons produced in primary and secondary collisions have such short lifetimes that they travel negligible distances before decaying, each into two photons, which share the rest energy and kinetic energy of the meson. Each photon travels on the average only  $48 \text{ g./cm.}^2$  in air before undergoing pair production while passing near an atomic nucleus. The positron and electron thus produced generate new photons along their paths by radiation as they pass near nuclei; each radiates a photon of about half its own energy, plus numerous photons of lesser energy, in traveling about  $40 \text{ g./cm.}^2$ . The new photons in turn make new pairs of electrons and positrons, and these radiate additional photons. Thus a cascade shower or electronic cascade develops, the average energy per particle decreasing as the number grows. This is the principal means by which the secondary photons, electrons and positrons are created. Ultimately the energies of the photons become too small to make pairs, while the energies of the electrons are too low to permit radiation of further high-energy photons; the remaining photons are then lowered in energy by Compton scattering (see COMPTON EFFECT) and ultimately absorbed by the photoelectric process, while the energy of the electrons is absorbed by ionization.

Charged particles other than electrons and positrons do not directly initiate electronic cascades with significant probability; the radiation process requires sudden acceleration in the electric field of a nucleus and only electrons and positrons are light enough to be accelerated sufficiently. Their ratio of charge to mass is 207 times greater than that of their nearest competitor, the  $\mu$  meson. Cloud chambers are often equipped with lead plates; one of the chief purposes of this is to make possible the detection of photons and the recognition of positrons and electrons by their unique ability to produce cascade showers.

In a heavy, condensed material such as lead, the mean distance

between successive generations (called the "radiation length") is only 0.5 cm.; hence, electronic cascades develop rapidly and are usually absorbed within 5 to 10 cm. In contrast, the distance per generation in nuclear cascades or penetrating showers is 14 cm. in lead, and the total range is on the order of 1 m. Typical ranges of  $\mu$  mesons are even longer. Therefore electronic cascades are called "soft showers."

**8. Soft and Hard Components.**—Cosmic rays have often been divided roughly into two classes by the experimental distinction of whether or not they penetrate through 10 to 15 cm. of lead. From the above discussion, it may be concluded that the nonpenetrating or soft component includes almost all the photons, electrons and positrons, while the hard component includes most of the  $\mu$  mesons. The other particles discussed above are not so cleanly divided, but fall partly in the hard group and partly in the soft one, depending on their energies. These particles, however, are comparatively rare at sea level, where the marked distinction between soft and hard components was one of the clues that led to the discovery of the  $\mu$  meson.

**9. Transition Curves.**—Graphs of the counting rates of the various kinds of particles as functions of depth in the atmosphere are called atmospheric transition curves. The transition curve of the total number of charged particles reflects the combined effect of all the processes discussed above. Instruments carried in rockets have shown that above 40 km. (25 mi.) altitude, corresponding to 2 g./cm.<sup>2</sup> of residual air, there is practically no variation of counting rate until the Van Allen radiation belts are reached. Below 40 km., the rate rises until an altitude of 12.5 to 14 km. is reached (depending on the latitude). There the rate is a maximum. Below that altitude the rate decreases steadily, but more and more slowly as sea level is approached.

The maximum in the atmospheric transition curve is due to the multiplication of particles through the mechanisms of multiple meson production, nuclear cascades and cascade showers. At the top of the atmosphere the number of new particles produced exceeds the number of primaries absorbed, because the average energy is high. Lower in the atmosphere, the number of particles capable of the multiplicative processes is much smaller, and absorption predominates over new production. Near the maximum in the transition curve, the most abundant charged particles are positrons and electrons, while photons and slow neutrons are present in comparable number. At the top of the atmosphere the particles are all primary protons and heavier nuclei. Near sea level, the primaries are gone, the soft component has been mostly absorbed, and the most abundant remaining particles are  $\mu$  mesons.

The relative counting rates at the top of the atmosphere, at the maximum of the transition curve and at sea level, reflect the total multiplying power of the primaries and the penetrating power of their secondaries. The ratios therefore are indicative of the average primary energy and vary with latitude as expected. At the equator the three counting rates are in the ratio 3:20:1, while at latitude 41° the ratio is 7:28:1 and at 60° it is 24:35:1.

**10. N-component.**—N-component is the name given to those particles that are capable of producing nuclear interactions (stars and penetrating showers) with high efficiency. Like the names hard and soft components, the term is useful in making an experimental classification before the actual identities of all the particles are established. Primarily the N-component includes high-energy protons, neutrons and charged  $\pi$  mesons. The amount of N-component is found to vary in a particularly strong and yet simple way with depth in the atmosphere; namely, there is a continual exponential decrease, equal to a factor of 2 in every 82 g./cm.<sup>2</sup> The slow-neutron intensity varies similarly with depth, except very near the top of the atmosphere, where the first ones are generated.

**11. Extensive Air Showers.**—The most marvelous and complex of all cosmic-ray phenomena is what is known as an extensive air shower. It is what occurs when a primary of extremely high energy,  $10^{13}$  to  $10^{19}$  ev or more, enters the atmosphere. The individual events occurring in extensive air showers are just the same, qualitatively, as those outlined previously in this section. But the primary energy is so high that the cascade processes of

creation of particles can go on and on without exhausting the energy, until huge numbers of particles have been produced. All kinds of elementary particles have been found in extensive air showers, but by far the most numerous are photons, electrons and positrons. In some instances, the number in a single shower was found to exceed 10,000,000,000.

The particles in air showers do not all proceed in exactly the same direction; hence the adjective "extensive." There is a core near which many particles are densely clustered, but others are scattered and travel to the sides. Particles in single air showers have been detected more than 1,000 m. apart. The majority, however, land in an area 70 m. in radius (at sea level), and within about  $\frac{1}{10}$   $\mu$  sec. of each other. Of course, small showers containing just a few particles are much more frequent than the large ones; but the biggest air showers stir the wonder of scientists, for these showers represent macroscopic energies carried to the earth by submicroscopic particles. How high the energy can be is a challenging experimental question, and how to explain the acquisition of such energies is a disturbing physical and cosmological problem.

## VI. IMPORTANCE OF COSMIC RAYS

Cosmic radiation originally received the attention of scientists simply because the phenomenon posed a challenge to the understanding. But the study has led to findings of widespread interest in other areas of human knowledge, and even to concern about the effect of cosmic rays on life itself. (For the latter, see RADIATION: BIOLOGICAL EFFECTS; SPACE EXPLORATION.) It has long been known that cosmic rays are related to the origin of the aurora borealis, and to sporadic changes in atmospheric ionization that affect radio communications. Some other areas into which the study of cosmic radiation branches are discussed in the following paragraphs.

**1. Exploring the Distant.**—Each type of radiation striking the earth carries with it some information about the place where it originated and the space through which it traveled on its way. The equality of primary cosmic rays approaching the earth in all directions led to the previously mentioned suggestion by Fermi that interstellar space contains extensive magnetic fields associated with the gas clouds. The degree of uniformity of high-energy cosmic rays tells something about the extent and strength of these fields. The amount of secondary radiation accompanying the charged primary nuclei is related to the average density of matter in the space traversed by cosmic rays. The atomic composition of the primaries is related to the temperature in the region of their source. The existence of high-energy particles is indicative of extremely violent processes going on in distant nebulae, and the energy spectrum of the cosmic rays specifies some of the detailed conditions in those turbulent regions. Thus, the study of cosmic radiation is part of astronomy.

**2. Exploring the Tiny.**—The high energies possessed by some cosmic rays make them a unique probe for investigating nature on a small scale, as in the interior of a nucleus, and in the structure of elementary particles themselves. Associated with particles having a momentum  $p$  is a wave length equal to  $h/p$  (where  $h$  is Planck's constant,  $6.6 \times 10^{-27}$  erg-sec.). This wave length divided by  $2\pi$  is the smallest length that plays a role in the interactions of the particles (see QUANTUM MECHANICS). One of the reasons that high-energy particle accelerators are constructed is to attempt to resolve this length. A proton of energy 30 Bev, the highest artificially produced energy in 1961, upon colliding with another proton yields a resolution of  $5 \times 10^{-15}$  cm. Cosmic-ray energies extend beyond  $10^{10}$  Bev, providing resolution in such collisions, in principle, to  $3 \times 10^{-19}$  cm.

It had not yet been possible by 1961 to take full advantage of this resolution, but numerous details of matter on a fine scale had been brought to light by the cosmic rays. They led to the discovery of many of the known elementary particles. They provided the first evidence of positron-electron pair creation and the cascade showers predicted by electromagnetic theory. They illustrated in many ways Albert Einstein's principle of mass-energy equivalence as well as other predictions of special relativity.

such as the change of length and time scales at velocities close to that of light. And they have revealed, at least approximately, the energy exchanges and multiple production of new particles that occur in the ultraenergetic nuclear collisions mentioned above.

**3. Tracing the Past.**—Nuclear collisions of cosmic rays in the atmosphere leave in their wake a substantial number of radioactive atoms—not enough to add significantly to the natural radioactivity of terrestrial origin, but enough to provide a usable, steady source of tracer elements which can be used to study various natural processes of circulation, mixing and separation occurring on earth.

The first use of such a tracer was developed by W. F. Libby and his co-workers in 1946, using the radioactive isotope most abundantly produced by cosmic radiation, carbon-14 ( $C^{14}$ ). Radio-carbon dating (*q.v.*) may be likened to reading a clock that is wound up by cosmic rays. High in the atmosphere, secondary neutrons produced by cosmic rays are captured by the nuclei of nitrogen atoms, creating  $C^{14}$  atoms, which are thereafter oxidized to carbon dioxide. The carbon dioxide is absorbed from the air by plants, which are in turn consumed by animals, and thus the radioactive carbon becomes a part of all organic matter.

Many other tracers besides  $C^{14}$  are produced by cosmic rays, mostly through spallation (*see* NUCLEUS: *Nuclear Reactions*) of atoms of nitrogen, oxygen and argon in the atmosphere. In meteorites and tektites, still further isotopes are produced by cosmic-ray interactions with the natural magnesium, silicon, aluminum, nickel, iron, cobalt, etc., of the meteoritic material. The table lists discovered isotopes which in air or in meteorites are principally of cosmic-ray origin.

*Isotopes of Cosmic-Ray Origin and Their Half Lives*

Isotope	Half life	Isotope	Half life	Isotope	Half life
$C^{14}$	55 min.	$Co^{60}$	5.2 yr.	$Ni^{59}$	0.10 million yr.
$Pu^{239}$	14.3 days	$H^3$	12.3 yr.	$Ca^{41}$	0.11 million yr.
$Pu^{240}$	24.4 days	$Ni^{60}$	125 yr.	$Fe^{56}$	0.3 million yr.
$Be^7$	53.6 days	$Mn^{54}$	140 yr.	$Cl^{36}$	0.31 million yr.
$S^{35}$	87.1 days	$Ar^{39}$	265 yr.	$Al^{28}$	1.0 million yr.
$Na^{22}$	2.6 yr.	$Si^{31}$	700 yr.	$Be^{10}$	2.7 million yr.
$Fe^{59}$	2.6 yr.	$Ti^{44}$	1,000 yr.	$Ar^{36}$	stable
$Ar^{41}$	$\geq 3.5$ yr.	$C^{14}$	5,700 yr.	$Ar^{38}$	stable
				$He^3$	stable

\*Production detected in atmosphere. (The others have been observed in meteoritic material.)

Dating by cosmic-ray-produced radioactivity depends upon knowledge of the average intensity of cosmic rays during the time when the isotope was being produced. Currently, a periodic variation of cosmic-ray intensity over the 11-year solar cycle is noticeable, but there is no firm evidence for a long-range trend. The amount of  $C^{14}$  on the ocean floor has shown that the average intensity of cosmic rays 30,000 yr. ago was equal to the present value within 10% to 20%, and the amount of  $Be^{10}$  indicates that over a period of 3,000,000 yr. the progressive change has been less than a factor of 2.

Most of the cosmic-ray-produced tracers were discovered in the years since 1954, and dating techniques are still being perfected. As it is learned how to read all these time clocks with accuracy and reliability, they will open to mankind a more and more complete record of both recent and ancient physical history on the earth, on the moon and planets and in the space beyond.

**4. Cosmological Effects.**—Cosmic radiation also seems to play a part in physical evolution on a cosmological scale. In the galaxy (*q.v.*) there exist magnetic fields, turbulent motions of ionized gases, cosmic rays and a gravitational field. All of these forms of energy and pressure interact on each other, and the total energy in the galaxy in each of these four forms is believed to be nearly the same, about  $10^{57}$  ergs. Therefore each of these types of energy plays an important role in the dynamical equilibrium of the galaxy and in its slow evolutionary changes.

The detailed interrelations between these forms of energy are complex and are not thoroughly understood, but may be summarized roughly as follows. Stellar explosions and galactic rotation, tapping reservoirs much greater than the four forms of energy listed above, feed energy into turbulent hydrodynamic motion of plasma (highly ionized gas) clouds. These motions generate magnetic fields because of the conductivity of the plasma, and the

changing magnetic fields accelerate cosmic-ray particles. The cosmic-ray acceleration damps the turbulent motion and associated fields until the energy per unit volume in these three forms is about the same. Gravitational contraction, which would increase the rotational velocity and the rate of star formation, is resisted by the resulting pressures due to the turbulent gas motion, magnetic fields and cosmic rays. Hence the evolutionary process goes slowly, as energy is gradually lost in radiation, viscous effects and leakage of cosmic rays from the galaxy. Meanwhile, the close interconnection of the various forces maintains an approximate energy balance.

A fifth quantity of energy in the galaxy, nearly equal to the four listed above, is the energy in starlight, but in this case the near equality may be coincidental. Nuclear processes in stars convert much more energy into light than into cosmic rays, but the light escapes from the galaxy in straight lines with no appreciable resistance, while the cosmic rays are restrained by the magnetic fields. These two large inequalities (*i.e.*, in production and in rate of escape) nearly compensate for each other, so that the energy density of starlight in the earth's region of the galaxy is less than that of cosmic rays by only a small factor. *See* STAR.

## VII. UNDISCOVERED PRIMARY COMPONENTS

The primary cosmic rays detected prior to 1961 were all charged particles which (except for those produced at the sun) had traveled for a long while in a medium occupied by irregular magnetic fields. The random deflections experienced in transit remove information from such cosmic rays about when and where they originated. Trying to resolve details of the distant universe with this radiation is like attempting visual astronomy through a dense atmospheric haze. But scientists were confident that there are weaker components of the cosmic rays which are neutral and therefore travel in straight lines through space. These components are high-energy photons and neutrinos. It was possible to predict in 1961 that success in detecting these components would be achieved before many years had elapsed, and that this radiation would convey important new kinds of astronomical information.

**1. Evidence of Neutral Components.**—As explained earlier, the gamma rays and neutrinos, as well as electrons, are a secondary effect of charged cosmic rays, produced abundantly in the atmosphere by decay of  $\pi$  and  $\mu$  mesons, which are created when the primary nuclei collide with nuclei in the atmosphere. Such collisions occur also in the regions of the cosmic-ray sources, and in the rarefied gas of the interstellar medium in which the charged cosmic rays wander. Evidence of the electrons arising in this way is given by the synchrotron radiation received from interstellar space and from numerous discrete sources. Independent evidence of nuclear collisions undergone by the cosmic rays before reaching the atmosphere lies in the presence of lithium, beryllium and boron among the cosmic rays, despite the virtual absence of these elements in stars.

**2. Predictions of Intensity.**—The intensity and energy spectrum of the photons and neutrinos from at least one extraterrestrial source—namely, the nuclear collisions of cosmic rays with gas in the galactic disk—could be predicted fairly accurately in 1960 because both the density of gas and the flux of cosmic rays in this region were moderately well known. The average number of photons or neutrinos from this source that have energy exceeding  $E$  Bev was computed to be  $5 \times 10^{-6}/E^{1.64}$  per square centimetre-second-steradian. The computed intensity coming from the direction of the centre of the galaxy was about 20 times this.

The computed intensity arising from other regions was subject to great uncertainty because of possible errors in the estimated density of matter and of cosmic rays in those regions. Measurement of this radiation is expected to help in establishing the density of matter and cosmic rays in distant regions, and in proving or disproving various theories about the conditions prevailing in supernovae and other unusual stars and galaxies.

**3. Problems of Detection.**—Detection of the primary photons was difficult prior to 1960 mainly because their number is less than 1% of the photons produced in the atmosphere by charged

cosmic rays. Space vehicles reduced the difficulty by enabling measurements to be made outside the atmosphere, although care had still to be exercised to avoid recording secondary photons produced in the vehicles themselves.

Detection of the neutrinos has the special difficulty of a very small cross section for interactions by which the neutrinos can be observed. The theoretical cross section at a neutrino energy of 1 Bev is only  $10^{-38}$  cm.<sup>2</sup> per nucleon in the instrument. Hence even if the counter were 10 m. thick, only 1 neutrino in 100,000,000,000 would be detected when it entered the counter. A bizarre method that has been suggested for studying astronomy with high-energy neutrinos is to erect a gigantic counter in a mine far underground, so as to avoid other kinds of radiation, and to wait patiently for very infrequent counts; these counts would signal events that had their origin many trillions of miles from the earth.

**COSMOGONY**, the branch of astronomy concerned with the evolutionary behaviour of the universe and the origin of its various characteristic features. While early cosmogonical theories were limited to the problem of the origin of our planetary system, modern cosmogony embraces the study of the origin of giant stellar galaxies, single and multiple stars, planetary systems in general and, finally, the origin of atoms of various chemical elements which constitute the universe.

The cornerstone of modern cosmogonical theories is the assumption that the system of galaxies scattered through the vast space of the universe is in the state of progressive expansion or dispersal. This conclusion, based on the observation of a red shift of spectral lines in the light coming from distant galaxies (see **COSMOLOGY: The 20th Century: Red Shifts**), led G. Lemaître in 1927 to formulate a broad cosmogonical hypothesis according to which the present high degree of differentiation of matter in space and the complexity of forms of various astronomical objects must have resulted from a violent explosion and subsequent dispersal of an originally highly compressed and intensely hot homogeneous material.

For almost three decades after its formulation, the theory of the expanding (or dispersing) universe suffered from an annoying contradiction: the age of the universe, as estimated from the observed rate of expansion (i.e., the mutual recession velocities of galaxies), was considerably shorter than the age of Earth as estimated by reliable geological methods and the age of stars of the Milky Way as given by more recent astrophysical studies. The discrepancy was not removed until 1952, when W. Baade showed that the distances between the galaxies are actually 2.5 times greater than was previously believed, which increases by the same factor the period of time which was necessary for the galaxies to reach their present separations. These new values of intergalactic distances give for the age of the universe the value of 5,000,000,000 ( $5 \times 10^9$ ) years, which is in perfect agreement with the age of stars and the age of Earth as given by the improved astrophysical and geological methods. Close coincidence among the figures obtained for the age of the universe, stars and planets indicates that all major astronomical features of the universe originated rather early in the beginning of its evolution, and that nothing very exciting has happened since then (except, of course, organic evolution).

Although the notion of an expanding universe is now accepted by the majority of scientists associated with this class of problems, there are a few who prefer to believe in a stationary universe and consider the observed red shift not as the result of recession of galaxies but rather as a consequence of some as yet unknown property of light quanta that causes them to lose a part of their

energy in traveling over long distances. However, none of the proponents of that point of view have been able to formulate any reasonable and consistent physical theory for such an energy depletion of light quanta. From the point of view of cosmogony the abolishment of the expansion theory would be quite catastrophic, since it would deprive scientists of a natural explanation of the coincidence of ages of different characteristic features of the universe; in fact, if the universe was not created 5,000,000,000 years ago it was certainly very extensively reorganized at that time, and the stationary cosmology cannot provide any reason for such reorganization.

**Origin of Galaxies According to "Conventional" Cosmogony.**—The original ideas of Lemaître concerning the evolutionary development of the universe from a certain starting point in the past were further developed (in 1948 and later years) by G. Gamow, who emphasized the importance of the gravitational effect of radiant energy during the early stages of expansion. According to Albert Einstein's principle of equivalence of mass and energy, light quanta possess a ponderable (i.e., gravitating) mass which is numerically equal to the amount of their energy divided by the square of the velocity of light, ( $M = E/c^2$ ). Under ordinary circumstances, the "weight" of light can be neglected; thus, for example, on a bright sunny day the total weight of light quanta traversing one cubic kilometre of atmospheric air is only 100,000,000 mg. However, the density of radiant energy increases very rapidly with the absolute (Kelvin) temperature  $T$  (proportionally to  $T^4$ ), and at very high temperatures, such as are encountered in the centre of the sun or in the core of an exploding atomic bomb, the weight of light quanta (in this case, high-frequency  $\gamma$ -rays) may be as high as one gram per litre. Using cosmological equations of the general theory of relativity (*q.v.*) and the basic laws of the thermodynamics of radiant energy, Gamow was able to show that during the first 250,000,000 years of the evolution of the universe the mass density of radiant energy was so high that it exceeded the density of ordinary matter. Under these circumstances, particles of matter could not aggregate into localized concentrations, and matter must have been dispersed uniformly through the space of the universe in the form of a thin gas. According to that theory, the temperature and density of the gas were given by:

$$T = \frac{1.5 \times 10^{10}}{t^{1/2}} \text{ } ^\circ \text{K.}, \text{ and } \rho = \frac{10^{-8}}{t^{3/2}} \text{ g./cm.}^3$$

where  $t$  is time in seconds counted from the date of the "beginning." Thus, for example, at the end of the first week the temperature of space was about the same as that found now in the centre of the sun, and the density of matter in it was comparable with the density of atmospheric air at an altitude of 100 mi.

As the expansion progressed, the density of radiation dropped faster than that of matter, and after 250,000,000 years the densities became equal to one another; at this time the temperature of space was well below the freezing point of water, and the density was somewhat lower than the present density of the interstellar gas (one hydrogen atom per cubic centimetre). Further expansion made matter gravitationally more important than radiant energy and gave rise to the first step in the differentiation of the originally homogeneous gas.

The breakup which followed can be described in terms of the principle of gravitational instability of extensive gas masses which was first formulated, in a somewhat different connection, by Sir James Jeans. According to Isaac Newton's original idea, each piece of matter attracts every other piece by a force of gravity; however, the force is negligibly small unless at least one of the two bodies is very massive (see **GRAVITATION**). The earth attracts the moon, forcing it to follow a circular orbit; the moon attracts Earth, producing ocean tides; Earth attracts an apple, making it fall down from a tree; an apple also attracts another apple hanging on the neighbouring branch, but in the last case the force is so small that it could be noticed only by using the most sensitive physical instruments. Similarly, gravitational air-to-air attraction in Earth's atmosphere can be neglected so that terrestrial gravity is considered to be the only acting force.

BY COURTESY OF MOUNT WILSON AND PALOMAR OBSERVATORIES

*Top left:* Spiral galaxy in Ursa Major as seen from the top. The central elliptical body contains only stars (stellar population, or type, II), while the spiral arms are formed by both stars and gas (stellar population I) from which new stars may be formed.

*Top right:* Spiral galaxy in Coma Berenices as seen edge on. Again, the central body is formed by stars alone. The dark band along the edge is

caused by obscuration from dust clouds in the arms.

*Bottom left:* Globular galaxy in Virgo. Formed by stars only (population II) with no gas or dust at all.

*Bottom right:* A cluster of galaxies in Leo showing spiral and elliptical types.

BY COURTESY OF (TOP LEFT, TOP RIGHT, BOTTOM LEFT) MOUNT WILSON AND PALOMAR OBSERVATORIES, (BOTTOM RIGHT) G. GAMOW

*Top left:* Globular cluster in Serpens located outside the arms of the Milky Way. Typical example of stellar population II  
*Top right:* Galactic cluster (Pleiades) located within spiral arms. An example of stellar population I, showing illuminated gas clouds  
*Bottom left:* Nebula in Monoceros, a region of the Milky Way containing

large amounts of stellar dust  
*Bottom right:* Drawing of the origin of the solar system. The sun, coming to life, is blowing off gaseous envelopes of protoplanets. (After G. P. Kuiper)

When dealing with gas masses spread over the unlimited expanses of the universe, however, this cannot be done, and the Newtonian attraction between different sections of the gas must be taken into consideration. Jeans showed that in this case the interplay of gravitational forces will lead to a breakup of homogeneous gas into individual gas clouds, and he gave simple formulas for calculating the masses and sizes of these clouds as a function of the density and temperature of the original gas. Applying Jeans's formulas to the conditions which must have existed in the expanding universe during the epoch when matter took over the leading role and gravitational instability came into play, Gamow found that the mass and size of individual gas clouds formed at that time were comparable with the average mass and size of stellar galaxies as they exist today. By that time space was dark and cold, and so were the newly formed gas clouds, or proto-galaxies, which were destined to develop into the shining stellar galaxies of today by the process of secondary condensation within their giant cool bodies.

**Origin of Galaxies According to "New" Cosmogony.**—In 1948 an entirely new and revolutionary theory was proposed in Cambridge, Eng., by H. Bondi, T. Gold and F. Hoyle, which, apart from its purely philosophical and mathematical merits, also circumvented the above-mentioned (and now nonexistent) discrepancy between the age of the universe as estimated from recession velocities and the age given by astrophysical and geological data. The new theory, known as steady-state cosmology, assumes that progressive dispersal of galaxies does not lead to rarefaction of the space of the universe because their place is taken by younger galaxies which condense from new matter that is being continuously created (from nothing) all through the intergalactic space. Since the rate of creation of new matter is assumed to be equal to the observed rate of dispersal of galaxies, the density of the galactic population of space remains constant in time, and the show goes on without beginning or end. As in the previously described theory, formation of new galaxies is ascribed to Jeans's gravitational instability, the new element being provided, however, according to D. W. Sciama, by gravitational action of the already existing galaxies. Since according to the steady-state theory the galactic population of space must represent a mixture of galaxies of all possible ages, scientists can choose for the age of our own galaxy any figure indicated by geological and astrophysical data. In fact, the present agreement between the geologically estimated age and the figure derived from the observed red shift must be considered in the new theory as coincidental.

The above-mentioned difference in conclusions concerning galactic ages between the conventional and new cosmologies (and corresponding cosmogonies) represents a very good testing point for comparison with the observed facts. According to conventional theory all galaxies were formed at about the same time, so that the galactic population in any region of space must be found in the same stage of evolution, progressively changing with time. On the other hand, the new theory predicted that in any given region of space there should be found a mixture of all possible evolutionary stages and that this mixture should remain invariant in time. Investigators in the 1960s did not yet have any well-developed theory of evolutionary changes of stellar galaxies resulting from the evolution of individual stars. It should be expected, however, that the age of a galaxy will be revealed by its stellar content (upper limit of stellar luminosity, relative number of stars of different spectral classes, etc.). Thus, according to the conventional theory, the stellar content of galaxies located in our neighbourhood must be similar to that of the Milky Way, while, in more distant groups of galaxies, there should be a different stellar content, since, because of the finite velocity of light, scientists observe them now as they were a long time ago. According to the new theory stellar content of the galaxies in our neighbourhood must vary considerably corresponding to the variety of their ages (with the average age being one-third the age of the Milky Way), while, on the other hand, there should be no difference between the mean stellar contents of the neighbouring and more distant galaxies (because of the steady-state hypothesis).

In 1961 Martin Ryle of Cambridge university published a paper which presented further evidence against the steady-state theory. Using a powerful radio telescope, he observed numerous point sources of cosmic radio waves (radio stars) which presumably arise from collisions between the galaxies (such as Cygnus A, which was identified optically by the 200-in. Palomar reflector). If observations at distances of 8,000,000 light years can be assumed to be equivalent to looking 8,000,000 years back in time, Ryle's observations indicated that, in contradiction to the steady-state theory, the mean density of matter in the universe decreases with the age of the universe. Thus, observational evidence available in the 1960s seemed to support the first set of theoretical conclusions and to contradict the second set.

The observational studies by Ryle in the course of the following four years forced Hoyle to "abdicate" from the steady-state theory. In an article published in 1965 Hoyle wrote, "Developments in the past two years, the discovery of the quasi-stellar sources (see below) in particular, have shown the situation to be more complex than it was at first thought to be. The indication of the radio counts is that the universe was more dense in the past than it is today."

**Galactic Shapes and Turbulent Motion.**—When proto-galaxies were formed (whether in a unique or a continuous process) by gravitational condensation of the homogeneous expanding gas, they must have continued to recede from each other, being left to themselves to proceed with their own internal evolution. It can be shown that, as long as they remained gaseous, the newly formed protogalaxies must have been undergoing steady contraction, losing their gravitational energy to the radiation filling the intergalactic space, and that this contraction could be stopped only by secondary condensation of the original gaseous material into a multitude of stars. During these early contractive stages, protogalaxies must have assumed their characteristic elliptical shapes, since, as was shown by Jeans, various observed galactic forms correspond to equilibrium configurations of rotating gas masses, and since, on the other hand, after the formation of stars the galaxies must have lost the internal coherence of material necessary for assuming regular geometrical shapes. Indeed, it can be easily shown that, whereas the mean free path of a molecule (i.e., the average distance traveled between collisions) in gaseous protogalaxies is very small compared with galactic dimensions, the mean free path of stars in the galaxies as they exist today is much larger than these dimensions; thus the regular shapes of the galaxies as seen at present cannot be ascribed to the statistical interaction between individual stars. Therefore, it may be said that present stellar galaxies represent the "fossilized forms" of the original gaseous protogalaxies, in the same sense that petrified wood is a fossil retaining the shape of the original plant.

In order to explain the formation of rotating condensations in the expanding primordial gas it is necessary to assume that, apart from the uniform expansion, this gas was also in the state of rather violent internal motion; i.e., in the turbulent state. Such an assumption also helps to explain the fact that, apart from regular recession velocities, galaxies also possess randomly distributed translational velocities which overlap on the simple pattern of the general dispersive motion. Indeed, the study of turbulence in fluid materials shows that this motion can be considered as an interplay of individual eddies of widely varying sizes, with the total energy about equally distributed between their translational and rotational motions. It may be added that the assumption of a violent turbulence in the primordial gas also helps to explain the origin of local fluctuations of density (compression and rarefaction eddies) which are necessary for application of Jeans's principle of gravitational instability.

Assuming the existence of turbulent motion in the original gas which condensed into the galaxies, a natural question is: What was the cause of this turbulence? The general answer is that turbulent motion is a natural state of any fluid material extending over a sufficiently large region of space and is to be expected to be present in all such cases, whether in the terrestrial atmosphere, in interstellar gas clouds or in the endless universe itself (see MECHANICS, FLUID: *Laminar and Turbulent Flow*). A more de-

tailed picture of origin of turbulent motion in the homogeneous gas condensing into galaxies is rather different in the conventional and in the new cosmogony. According to the former, the inhomogeneity in the distribution and motion of primordial gas may have originated during the transition from the radiation era to the matter era in the early history of the expanding universe. According to the latter, the turbulence in the universe is a self-perpetuating process and is produced by the movement of already existing galaxies through the masses of newly created gases.

**Origin of Stars.**—If the protogalaxies were condensed from a gas in a turbulent state of motion, it is natural to expect that after their formation turbulence continued to exist in their interiors. Thus, by repetition of the gravitational condensation process under the conditions of higher density, and probably lower temperature, further differentiation leading to the formation of individual stars could have taken place. The details of these processes, which led to the transformation of cool and dark gaseous protogalaxies into the shining stellar galaxies of today, are still a challenge to cosmogonical thought, but there is very good empirical evidence that all stars forming the bulk of the galactic population were formed almost simultaneously and very early in the history of the universe (probably within a few hundred million years after the formation of protogalaxies). To understand the situation requires studies of various galactic types and their stellar content. Most of the galaxies scattered through the space of the universe have regular spheroidal shapes ranging from almost perfect spheres to elongated ellipsoids; they are known generally as elliptical galaxies. Considerably rarer, but much more conspicuous, are the spiral galaxies, consisting of an ellipsoidal central body and a pair of shining spiral arms spreading out along the equatorial plane (see GALAXY). Studies by W. Baade showed that there are striking differences in respect to stellar population and interstellar material between these two types of galaxies:

**Population (or Type) I.**—The region of the spiral arms, which comprises comparatively small fractions of the number of all stars (best known to astronomers because we on Earth live inside a spiral arm of our galaxy), contains about half its material in the form of stars and another half in the form of interstellar material (gas and dust). It also contains blue giant stars which are so bright that no nuclear energy sources could have kept them going since the formation of our galaxy 5,000,000,000 years ago; evidently these stars were condensed from interstellar material at a more recent date.

**Population (or Type) II.**—Central bodies of spiral galaxies, and all elliptical galaxies, contain no interstellar material whatsoever, and their stellar content is limited to stars which can live for 5,000,000,000 years or more. Studies by M. Schwarzschild and A. R. Sandage led to the conclusion that the stars of population II must have originated at the same time ( $5 \times 10^9$  years ago) and are observed now in various stages of evolution depending on their different life spans, which in their turn depend on their original masses (same "calendar age," but different "genetic ages"). The conclusion, then, is that the process of star formation in elliptical galaxies and central bodies of spiral ones was 100% completed very early in the history of the universe, whereas spiral arms may represent, at least partially, later formations in which the process of condensation of interstellar material into stars is still going on.

While the formation of the main bulk of stars constituting population II was not yet clearly understood by the 1960s, some advances had been made in the theory of stellar formation from the interstellar material of spiral arms. The first steps in this direction were made by Jeans, who developed for this purpose the above-mentioned theory of gravitational instability and was able to show that, with reasonable assumptions concerning the density and temperature of the interstellar gas, correct values are obtained for the masses of condensing stars. Later, the original Jeans theory was extended by L. Spitzer and by F. L. Whipple, who stressed the importance of the radiation emitted by the already existing stars on the formation process of the new ones. It is well known that light incident on any material object produces a force in the general direction of incidence. In most cases this radiation pressure is negligibly small; e.g., nobody worries about the effect of floodlights on tennis balls during a night tournament. However, under cosmic conditions, with dust particles of about one micron in diameter, the effect of radiation pressure becomes quite important. In the case of a single particle in interstellar space, the net effect of stellar light falling on

it from all different directions will be zero, but if there are two such particles, each of them will cast a shadow, and in the shadow there is no radiation to produce a force. The fact that no radiation pressure acts on the faces of two particles turned to one another results in a net force pushing them together, and it can be shown that, for particles of the size of interstellar dust, this force may be hundreds of times stronger than the force of gravity between them. In this way radiation pressure of the existing stars can accelerate a comparatively slow condensation process caused by gravitational instability alone.

It may often happen that in the process of condensation of such a cloud, the cloud will possess too much rotational momentum to develop into a single stable star. In such cases the formation of two or more stellar bodies bound together by gravitational forces may be expected, and this accounts for the fact that among the stars in our galaxy double and multiple systems represent a rule rather than an exception. (See INTERSTELLAR MATTER, STAR.)

**Origin of Planetary Systems.**—As mentioned in the beginning of this article, the problem of the origin of the planetary system represents the oldest and, originally, the only problem of cosmogony. According to the original ideas of I. Kant and P. S. de Laplace the planets condensed from the primordial solar nebula, a flat, fast-rotating, gaseous disk which must have surrounded our sun during the early days of its existence. During the second half of the 19th century the Kant-Laplace hypothesis was subjected to severe criticism by J. C. Maxwell, who showed that, if all the matter contained in the known planets were once distributed around the sun in the form of such a disk, the shearing forces of differential rotation would have prohibited the matter from ever condensing into individual planets. The expected result of condensation would be rather a multitude of very small bodies, such as those forming the rings of Saturn. As the result of Maxwell's criticism, the Kant-Laplace views were rejected from planetary cosmogony and replaced by the so-called collision theory proposed independently by Jeans and by T. C. Chamberlin and F. R. Moulton at the beginning of the 20th century. According to this theory, which is similar to the views expressed by G. Buffon in the 18th century, planets were formed as a result of a violent collision between the sun and some other passing star. Since such collisions between two stars represent extremely rare events in the stellar traffic within our galaxy, our planetary system was supposed to be unique, or at least one of the few, in the entire stellar system of the Milky Way.

The collision theory, which dominated planetary cosmogony during the first decades of the 20th century, was finally disposed of in 1944 by the work of C. F. von Weizsäcker, who brought the problem back to the "parthenogenetic" ideas of Kant and Laplace by indicating that the old Maxwell criticism cannot hold in view of new knowledge concerning chemical constitution of the material forming the universe. In fact, in Maxwell's time, and up to the end of the third decade of the 20th century, it was generally believed that the sun, stars and interstellar material have the same constitution as Earth, being principally composed of silicon, iron, oxygen and a few other elements forming different abundant minerals. The great turnabout in astrophysics occurred when it was found that this is not true, and that the most abundant terrestrial elements form less than 1% of the average composition of the cosmos. The remaining 99% is provided by a half-and-half mixture of hydrogen and helium gases. Thus, argued Weizsäcker, the original solar nebula must have had a much larger mass than that contained in the planets today, the excess of hydrogen and helium being somehow lost after the formation of planetary bodies. With the total mass of the original solar nebula increased almost a hundredfold, Maxwell's old argument was no longer valid, and it was possible to return to the old ideas of Kant and Laplace, which visualized the formation of planets by gravitational condensation in the primordial solar nebula.

These basic ideas of Weizsäcker were further developed and brought into the form of a self-consistent theory by G. P. Kuiper. He estimated that the original solar nebula possessed a mass of about 10% of the solar mass, and that its breakup caused by gravi-

tational forces must have led to individual condensations, known as protoplanets, each with a mass of about 1% of the solar mass. These protoplanets must have had the same chemical constitution as the original interstellar material, being formed by 99% hydrogen and helium gases and only 1% (or even less) of the most abundant terrestrial elements in the form of fine dust. The dust particles gradually settled toward the centre of the protoplanets, forming solid spherical cores. The important point of Kuiper's theory is that the formation of protoplanets took place in darkness, since the sun itself was not yet sufficiently condensed to emit any appreciable light. When, later on, the body of the sun contracted to almost its present size, and its surface temperature went up to several thousand degrees, it began to pour intensive radiation into the space around it. Under the action of the radiation pressure of sunlight (mostly ultraviolet rays) the hydrogen-helium envelopes of the protoplanets, especially of those which were nearest to the sun, were gradually blown off into interstellar space, and for a while the planets looked very much as the comets do today, with giant luminous tails trailing behind their bodies. In the case of planets located closer to the sun (Mercury, Venus, Earth and Mars) the original hydrogen-helium envelopes were completely blown off, and the planets were left in the form of solid rocky bodies with negligibly small layers of atmosphere. (Present atmospheres of Earth and inner planets are presumably of later origin, being formed by oxygen and nitrogen gases liberated from the solid crust.) In the case of the outer planets, such as Jupiter and Saturn, a considerable part of the original envelopes was left over, and their giant bodies, as seen on photographs, are actually nothing but gaseous spheres composed of hydrogen and helium, with small solid cores hidden in their deep interiors. Kuiper also showed that formation of planetary systems can be considered as a special case of the formation of binary or multiple stars when, because of the distribution of velocities and angular momenta in the body of the original contracting nebula ("protostar"), it breaks up into one very large and several much smaller bodies. Extrapolating observational data concerning the number of binaries with different mass ratios, he concluded that formation of planetary systems similar to ours must take place in 1 out of 100 cases. Considering that there are approximately  $10^{11}$  stars in our galaxy, it must be concluded that  $10^9$  of them possess planetary systems, and on millions of those physical conditions may be very close to those encountered on Earth. Most likely life is flourishing on them too.

**Origin of Satellites and the Moon.**—The process of formation of satellites around the planets of the solar system must have been similar to, though on a smaller scale than, the process of formation of the planets themselves, and it will not be discussed here in any detail. A peculiar situation arises, however, in the case of the moon, which stands apart from other satellites because of its comparatively large mass; in fact, whereas the masses of all other satellites are several thousand times smaller than the masses of their parent planets, the moon is only 81 times lighter than Earth. It seems that the formation of the Earth-moon system should be rather compared with the formation of a binary star, in which two independent cores are formed within the original gaseous envelope. If this is true, the moon and Earth must have been very close together during the early time after their formation—a conclusion which is substantiated by the classical work of G. Darwin on the secular motion of the moon. Indeed, Darwin showed that dissipation of energy by lunar tides in terrestrial oceans is slowly driving the moon farther and farther away from Earth, and, extrapolating back in time, he came to the conclusion that a few thousand million years ago Earth and the moon were indeed very close neighbours.

**Origin of Chemical Elements.**—One of the methods for estimating the age of the universe is based on the study of certain natural radioactive elements—uranium-238, uranium-235 and thorium-232—and their decay products, lead-206, 207 and 208 (see RADIOACTIVITY). Starting with present abundances of these atomic species and extrapolating back in time, using the known decay constants, reveals that in the past there were smaller and smaller amounts of lead isotopes and larger and larger

amounts of radioactive elements. Such an extrapolation breaks down, however, if one tries to go back farther than 5,000,000,000 years, since at that date the extrapolated amount of lead-207 (the end product of the fastest-decaying uranium isotope, 235) becomes zero; if uranium-235 had been steadily decaying for a longer time than that, it would have produced more lead-207 than is actually found. Of course, this method gives only an upper limit for the age, since some lead-207 could be due not to the decay of uranium-235 but to independent production along with all other elements. Nevertheless, the date of formation of natural radioactive elements, and presumably of all other elements, may be set close to the date of the "beginning" as estimated by other methods.

Since, according to "conventional" cosmology, early stages of the evolution of our universe were characterized by extremely high temperature and comparatively high densities, it is logical to venture a hypothesis according to which the present relative abundances of various chemical elements and their isotopes were determined, at least partially, by thermonuclear reactions which must have taken place in those early days (see NUCLEUS: *Nuclear Reactions*). Calculations in this direction were carried out in 1947 and in following years by R. Alpher, H. Bethe, G. Gamow and R. Derman. Noticing that, under the physical conditions involved, the material of the young universe must have consisted entirely of a mixture of free neutrons, protons and electrons (*ylem*, or *hyle*, according to an old term used by Aristotle), these men visualized the formation of heavier elements as a progressive aggregation process, which must have started when the originally very high temperature dropped to a value at which nuclear bonding between protons and neutrons became possible. Using data on neutron-capture cross sections, they were indeed able to show that the theoretical curve giving relative abundances of elements in the universe is in reasonably good agreement with the empirical curve. In particular, the sharp drop of the empirical curve for the first half of the periodic system and its approximate constancy for the second half come as a direct result of the observed variation of neutron-capture cross sections with the atomic number of the bombarded element. Further calculations in this direction were carried out by E. Fermi and A. Turkevich, who limited themselves to only the lightest nuclei (neutrons, protons, deuterium, tritium, helium-3 and helium-4) but took into account all the details of expected thermonuclear reactions. They came out with the result that, by the end of the aggregation process, about 99% of matter would be roughly a half-and-half mixture of hydrogen and helium (in good agreement with observed facts) and about 1% would be in the form of deuterium and helium-3 which should serve as the centres of further aggregations. These calculations, however, came to a serious difficulty of building up the elements beyond helium, because of the absence of any stable nuclei with a mass number of five. It is interesting to note that, according to this theory, formation of elements took place during the first half-hour of the existence of the universe. It should not sound so incredible, however, if it is remembered that half an hour stands in the same ratio to 5,000,000,000 years as one microsecond (the nuclear reaction period in an exploding atomic bomb) stands to a few years' period, after which radioactive fission fragments are still noticeable at an atomic-bomb explosion site. (See THERMONUCLEAR REACTIONS.)

It must be noted also, however, that although the main processes of element formation (in particular the establishment of the hydrogen-helium ratio) could have taken place during the very early stages of the evolution of the universe, some further adjustments undoubtedly have taken place during subsequent periods. Thus, for example, spectroscopic data clearly indicate that stars of population I have, at least in their atmospheres, a hundred times larger percentage of heavier metallic elements than do the stars of population II (see SPECTROSCOPY, ASTRONOMICAL). Also, in some stars are found spectral lines belonging to the unstable element technetium (atomic number 43), which has been produced artificially in nuclear reactors and whose longest living isotope has a half-life of only 200,000 years. It is difficult to say whether these differences are due to some kind of nuclear reactions involving

neutron production that take place in the central regions of stars, or whether purely surface effects caused (for example) by high-energy cosmic-ray bombardment are responsible.

Another interesting fact is that the exponential decrease of the luminosity of supernovae has a half-life of 55 days, which coincides exactly with the half-life period of the transuranium element, californium-254, which undergoes spontaneous fission with the liberation of 220 Mev of nuclear energy. It is possible that californium-254 is produced during the explosions of supernovae, and that its slow decay supplies the energy for the later stages of supernovae. (See NOVA AND SUPERNOVA.)

In contrast with the above-described considerations based on the "conventional" cosmology, the steady-state theory, according to which matter is continuously created in the form of thin hydrogen gas, has to look elsewhere for the aggregation process leading to the formation of heavier elements. According to F. Hoyle, formation of heavier elements is taking place in the interiors of supernovae, and these newly formed elements are scattered around and mixed with the interstellar hydrogen gas by the force of explosion. In 1957 a considerable amount of work on the origin of elements in stars was carried on by Hoyle, and by E. Margaret Burbidge, G. R. Burbidge and William A. Fowler. Their work made it seem plausible that heavy elements may be produced in supernovae explosions, even though the number of supernovae which must have flared up since the origin of our galaxy seems to be by several orders of magnitudes too small to account for all heavy elements present in our galaxy.

**Quasi-Stellar Radio Sources.**—In 1961 M. Schmidt and A. Sandage of the Mt. Wilson and Palomar observatories discovered peculiar light and radio sources which became known as quasi-stellar radio sources or quasars. They represent a great mystery in modern astronomy. Their optical spectra show an extremely large red shift of lines, and in some cases the Lyman lines of hydrogen spectra, normally located in the far ultraviolet, are shifted all the way to the visible light region. Being interpreted as Doppler effect, this would indicate that these objects are located much farther away in space and are much more luminous than any galaxies previously discovered. Since, because of the finite speed of light, the expression "located very far in space" is equivalent to the expression "seen as they looked a very long time ago," one may conclude that these objects represent the very early states of galactic evolution, and that their study will reveal how our universe looked in the early stages of its development. See QUASI-STELLAR RADIO SOURCES.

**COSMOLOGY**, in the broadest sense of the word, is that branch of learning which treats of the universe as an ordered system. The name is derived from the Greek *kosmos* ("order," "harmony," "the world"), plus *logos* ("word," "discourse"). Cosmology is that framework of concepts and relations which man erects, in satisfaction of some emotional or intellectual drive, for the purpose of bringing descriptive order into the world as a whole, including himself as one of its elements. As such, it is confined to a description of the salient features of the observed universe, in terms of such categories as space and time and matter, leaving questions concerning the origin, inner nature and purpose of the universe to the related branches of cosmogony, ontology and teleology (q.v.).

The cosmologies which man has set up at various times and in various localities inevitably reflect the physical and intellectual environment in which he lived, including above all the interests and the culture of that particular society to which he belonged. For in attempting to bring order into the universe as a whole, he

must hew to those lines of thought by which he has already brought order into that portion with which he is most familiar. The resulting cosmology will accordingly reflect the sociological, philosophical or scientific predilections of the individual and his group.

Cosmologies, as may therefore be expected, run the gamut from simple pictures projected from the everyday objects of a primitive society, through the metaphysical constructs of various philosophers, to the sophisticated mathematical models presented by modern science. In keeping with this viewpoint and with the fact that western man has for some time been immersed in an era characterized by the scientific outlook, the present account will be devoted mainly to the growth and present status of cosmology as a branch of natural science.

## HISTORY

**Early Cosmologies.**—Man finds himself on an earth, inhabiting a land mass surrounded by seas and blanketed by a gaseous atmosphere. By day the sun dominates his sky, followed at night by the moon and the host of stars, among which wander the five erratic planets. Imposed upon this regularity are the passing phenomena of clouds and rain and lightning, of shooting stars and occasional comets, and of the frightful moments when the light from the sun or moon is wiped out by an eclipse. Faced with this confusing multiplicity, beyond his physical power to control, man seeks to master it symbolically by reducing it to order—by constructing a cosmology relating its parts with each other and with man himself, welding them into a conceptual whole.

In primitive cultures, man has sought to attain this symbolic mastery by picturing the universe in terms of objects familiar to him in his everyday life. Thus one of the primitive tribes of ancient India pictured the earth as a huge tea tray, supported on the backs of three giant elephants, which in turn stood on the shell of an enormous tortoise. To the Egyptians the sky was a heavenly Nile, along which the sun-god Ra sailed from east to west each day, to return at night to his starting point through the subterranean abode of the dead; this god was occasionally thrown into eclipse when his boat was attacked by a great serpent.

Of more interest to the western tradition is the primitive cosmology of Babylonia, for from it can be traced both the scientific view which dominates modern times and the rival mythological view which threatened the eclipse of the scientific approach in the dark ages of Europe. In it the central earth is a great mountain, hollow underneath, surrounded and supported by a vast ocean—the deep—and under it is the abode of the dead. Above the earth is the solid vault of heaven—the firmament—resting on the waters of the deep and dividing the upper waters from the lower; across the firmament move the sun and moon and the heavenly host of stars. (See ASTRONOMY: History of Astronomy.)

**Contributions of the Greeks.**—Greek physical science arose in the Mediterranean colonies in the 6th century B.C., flourished on the mainland during the next two centuries, whence it passed on to Alexandria—and shortly after the dawn of the Christian era stagnated until resurrected in the Renaissance. These golden centuries saw great advances in observational astronomy and mathematics and with them the emergence of cosmological theory from the mythological form impressed upon it by the Babylonians and the Egyptians. Physics had failed, however, to keep pace with its sister sciences; lacking a firm mechanical base and constrained by metaphysical dogma, Greek cosmology developed in the direction of ever more intricate geometrical models.

Throughout the main line of development, from Thales of Miletus (c. 600 B.C.) to Ptolemy of Alexandria (c. 150 A.D.), it was taken for granted that the earth was the immobile centre of the universe about which the heavens daily rotated. The chief importance of those who took exception, such as Heraclides Ponticus (4th century B.C.) and Aristarchus of Samos (c. 270 B.C.), seems to have been to supply a classical source upon which the innovators of later centuries could call for support, for their views were firmly rejected at the time on spurious reasoning or on dogmatic grounds. A second, even more grievous fault was that the idealistic philosophies of the Pythagoreans and of Plato

required that the motions of the heavenly bodies be explained in terms of uniform motion in circles. In the case of the stars this could readily be done merely by assuming that they were attached to a great sphere which rotated daily about the earth, but to account for the more irregular motions of the seven wanderers (*i.e.*, the sun, the moon and the five planets then known) led to great complications. The attempt by Eudoxus (408–355 B.C.) to solve this problem in terms of motion on homocentric spheres required 27 spheres, and in the form adopted by Aristotle (384–322 B.C.) 55 were required. But no such solution could account for the apparent changes in the distance of some of the bodies from the earth. The geocentric motions were augmented by motion in eccentric circles and in epicycles—the latter being uniform motion in circles whose centres were themselves in uniform circular motion about the earth. This cosmological model attained its most perfect expression in the work of Ptolemy, in which form it was handed down, with minor modifications by the Arabs, through the centuries to the reawakening west.

With this legacy went other positive contributions of the Greeks—the sphericity of the earth, the nature of the moon's light and some estimates of the sizes and distances of the principal heavenly bodies. From the difference in the declinations of the sun observed from two different points on the earth, Eratosthenes of Alexandria (*c.* 276–*c.* 192 B.C.) computed the circumference of the earth to be 252,000 stadia, which gives as the radius of the earth a figure only 25 mi. short of its true polar radius. From observations of the breadth of the earth's shadow during a lunar eclipse, the work of Hipparchus (*fl.* 146–127 B.C.) enables calculation of values of the moon's radius and distance, in terms of the earth's radius, which are within 8% of their true values; his distance for the sun, however, was only about one-tenth the true value. No estimate of the distance to the starry vault could be given, but it was generally held to be immense, though limited to a finite value.

**The Copernican Revolution.**—With the onset of the dark ages, cosmology was cast back into the primitive state from which Greek science had raised it. "Pagan" views were denounced as at variance with scripture. But with the rise of scholasticism in the 13th century Aristotle was firmly established in the schools, with church approval. Beyond this the scholastics would not go, with the exceptions of such rare minds as Roger Bacon (*c.* 1214–94), and the breakthrough to free thought in natural science had in addition the heavy blanket of the new Aristotelianism to throw off.

This breakthrough was initiated by Nicolaus Copernicus (1473–1543) in his immortal *De revolutionibus* (1543). In it he adopted the rotation of the earth to account for the diurnal motion of the stars and deposed the earth from its position as the centre of motion of the universe by allowing it and the other planets to move about the sun. A few in the succeeding generations seized upon Copernicus' views, and two of them, Thomas Digges and Giordano Bruno, took the further step of assuming an infinite universe populated with an infinity of worlds. But the times were not ripe for the general acceptance of the Copernican system; for one thing, the sterile Aristotelian mechanics had not yet been replaced by a more profound understanding of the nature of motion, and for another the Renaissance had ground to a halt in the bitter conflict between the church and the reformers, neither of whom would countenance such heterodoxy.

Bold as was his willingness to shift the centre of the universe from the earth to the sun, Copernicus was still bound by the Greek dogma that the motions of the heavenly bodies must at most be a combination of uniform circular motions. His system was in consequence little better than Ptolemy's in accounting for the apparent motions of the planets, as judged from the vantage point of the earth. The discrepancies were made more acute by the superb observations of Tycho Brahe (1546–1601), who himself espoused a geocentric system in which the planets described epicyclic orbits centred upon the moving sun, an ingenious improvement of the Ptolemaic system and one equivalent in its predictions to the Copernican.

Tycho's observations were handed on to his brilliant assistant

Johannes Kepler (1571–1630), who devoted his life to the problem of determining the organic structure of the solar system, under the inspiration of a neo-Pythagorean metaphysics. Kepler's exhaustive study of the motion of Mars led him to the conclusion that it described an ellipse at one focus of which the sun was situated. This empirical discovery, extended to the other planets, did away once and for all with the artificial restriction to uniform circular motion imposed a priori by the Greeks, and at the same time established the sun as the natural point of reference of the planetary system. Kepler's later investigations on the relative sizes of the planetary orbits led him (1619) to his third law, that the squares of the periods of revolution of the planets are proportional to the cubes of their mean distances from the sun (*see ORBIT*). Superimposed on this hard kernel of fact was a penumbra of fancy which history has mercifully passed over, including a mystical computation of the radius of the solid sphere upon which the stars are mounted, recalled here only to emphasize the widening celestial horizons of the intervening centuries. Kepler estimated the radius of this ultimate sphere at 60,000,000 earth radii, about 2,560 times the mean radius of the earth's orbit, or in modern units about one twenty-fifth of a light-year—where one light-year is the distance light travels in one year, the distance from the sun to the earth being about eight light-minutes and the actual distance to the nearest star about four light-years.

The Copernican revolution may be said to have been completed with Galileo Galilei (1564–1642), whose telescope revealed the satellites of Jupiter and the rings of Saturn, stripping the earth once and for all of the claim to being the only body about which all others must be considered to rotate. Galileo's observations thus assured the sun of its central position among the planets, but at the same time his resolution of the Milky Way into a great collection of stars presaged the subservient position to which the sun itself was to be relegated by later observation.

**The Newtonian Era.**—In the year of the death of Galileo was born Isaac Newton (1642–1727), the genius destined to bring order into the solar system and to furnish the tools—the new science of dynamics and the law of universal gravitation (1687)—for the extension of this order throughout the visible universe. The solid spheres, already shattered by the moons of Jupiter and the clearly extraterrestrial comet of 1577, were swept away and replaced by scientific law which accounts at once for terrestrial gravitation, the motion of the moon around the earth, of the earth and the other planets around the sun and of multiple stars around their centre of mass (*see CELESTIAL MECHANICS; GRAVITATION*).

The time was now ripe for the demotion of the sun itself and its eventual recognition as a minor member of that great system of stars that makes up the Milky Way. Newton himself promoted the cosmological and cosmogonical speculations initiated a century earlier by Digges and Bruno. In a letter written to Richard Bentley he stated, "But if the matter were evenly disposed throughout an infinite space . . . some of it would convene into one mass and some into another, so as to make an infinite number of great masses, scattered great distances from one another throughout all that infinite space. And thus might the sun and fixed stars be formed, supposing the matter were of a lucid nature." Thus arose the long line of scientific cosmogony, leading through Thomas Wright, Immanuel Kant and Pierre Simon de Laplace to the modern theories.

Observation did not lag behind theory. Foremost among the observers was Sir William Herschel (1738–1822), a musician by profession and an astronomer by choice, who launched an attack with telescopes of ever increasing power designed to extend knowledge beyond the confines of the solar system in an effort to discover the structure of the universe. Herschel discovered a seventh planet, Uranus (1781), and pushed on to the study of double stars, extending the rule of Newtonian gravitation into stellar space. Telescopic observation showed that the dimmer stars, as well as those visible to the naked eye, tend to cluster about the plane of the Milky Way, forming a lenticular figure whose thickness is but a small fraction of its diameter. Since the time of Edmund Halley it had been known that some of these "fixed" stars had proper motion, and Herschel concluded that the sun

itself had such a motion relative to the body of the system.

This completed the relegation of the sun to a relatively minor status among the stars of the galaxy, and it was natural to consider this stellar system as constituting the universe. But among the apparently nonstellar objects discernible to the unaided eye are two luminous patches, the nebulae M31 in Andromeda and M33 in Triangulum, to which the early Portuguese navigators added the two Magellanic Clouds visible from southern latitudes. The early telescopic observations showed that similar objects are quite common; Herschel compiled a list containing around 2,500, to which his son Sir John Herschel (1792-1871) added almost as many more. Sir William at first played with the idea that these lucid patches were in fact "island universes" comparable with the Milky Way in structure and content, but the proof of this hypothesis had to await a more profound knowledge of our own system and the development of the giant telescopes of the 20th century. It is known that a few of the nebulosities considered by the Herschels are in fact clouds of dust and gas within our own stellar system, but that the vast majority, including the elliptical and spiral nebulae, are truly extragalactic objects; it is with these extragalactic nebulae alone that the remainder of this article is concerned. (See GALAXY; NEBULA.)

Distance was the essential clue lacking to bring this grandiose picture into focus, a picture in which our own galaxy takes its place as only one of a collection of perhaps 1,000,000,000 similar systems within range of the 200-in. Hale reflector telescope on Palomar mountain in California. But whereas the Greeks had a quite accurate knowledge of the distance to the moon, even the order of magnitude of the distance to the sun was not known with certainty until the time of Newton, and further centuries were to elapse before the distance to even the nearer stars could be measured. The modern era in astronomical measurement may be said to have begun with G. D. Cassini, who in 1672 placed the sun at 87,000,000 mi. from the earth—a figure about 6% below the true mean value. This opened the way for determination of the distances to the nearer stars, for as the earth moved around the sun the apparent position of a star should show an annual shift or parallax (*q.v.*), the amount of which depends on the ratio of the distances to the sun and to the star. It was not until 1838 that this trigonometrical method was used with full success, when F. W. Bessel placed the star 61 Cygni at the comparatively enormous distance of 11 light-years (65,000,000,000,000 mi.).

The distances of only the nearest stars can be obtained by this method; other criteria had to be found before man could measure the full extent of even the visible universe. Such an attempt had already been made by Sir William Herschel, by assuming that all stars had the same intrinsic brightness as the sun and attributing differences in apparent brightness to the effects of distance—a poor criterion, because it was later found that stars vary enormously in intrinsic brightness, and the sun is quite far down in the scale. Nevertheless, brightness is the essential clue which led from the modest parallactic distances through the visible portions of the galaxy to its nearer neighbours, the Magellanic Clouds and Andromeda, thence to the nebular field and eventually to the great clusters of nebulae at the utmost limits of the 200-in. telescope—a span estimated at the almost inconceivable distance of 2,500,000,000 light-years, 600,000,000 times the distance to the nearest known star. The new tool of radio astronomy (*q.v.*) promises the possibility of revealing even greater distances than this, perhaps through the evidence of more distant sources similar to that provided by two colliding nebulae in Cygnus.

### THE 20th CENTURY

**Distances of Nebulae.**—The impetus to the development of this brightness clue to the distances of extragalactic nebulae was the discovery in 1912 by Henrietta Leavitt at Harvard of a remarkable relation between the periods and luminosities of certain variable stars in the Small Magellanic Cloud, called Cepheids because of their similarity to the variable  $\delta$  Cephei within our own system (see STAR: *Stellar Variability*). By the year 1923 Cepheids were discovered in the Triangulum and Andromeda nebulae by J. C. Duncan and by E. P. Hubble at Mt. Wilson and,

with the aid of the period-luminosity relation perfected in the meantime by H. Shapley, were judged to be almost 1,000,000 light-years away, well outside the confines of the galaxy. A yet more powerful tool for the extension of distance stems from the discovery in 1917 by G. W. Ritchey of novae in Andromeda and other nebulae, a tool whose range was later vastly increased by the recognition of the class of supernovae, stars such as Tycho's star of 1572 which at their brightest rival an entire nebula in the rate of output of energy (see NOVA AND SUPERNOVA). Largely through the work of Hubble there were added to these brightness criteria of distance certain types of supergiant stars and finally nebulae themselves. Later a major recalibration of these distance scales was found necessary, beginning with a reconsideration of Cepheid magnitudes by W. Baade and extending to the bright-star criteria, which in turn forced a recalibration of the nebulae used as distance criteria. This work resulted in a trebling of the distance assigned to the remoter nebulae.

The problem of determining time scales is intimately bound up with this problem of distance, with the velocity of light in some cases forming a bridge between the two. It is clear that the actual period of a few decades over which detailed observations have been possible is but an instant in the life of a nebula; astronomers are accordingly confined, with the exception of such transient phenomena as novae, to the observation of states and trends. From these data, such as Hubble's constant discussed below, times which must play an important role in nebular theory can indirectly be inferred. In this category may be included times implied by theories of stellar structure, such as the age of 5,000,000,000 years attributed by M. Schwarzschild and his collaborators to the population II stars, which predominate in elliptical nebulae and in the nuclei of spiral nebulae. Furthermore, distance itself here is of assistance, because light being observed left the more distant nebulae thousands of millions of years ago. Observations should therefore result in data relevant to the evolution of nebulae, even if these all had a common time of origin. A promising excursion into this field was made in 1948 by J. Stebbins and A. E. Whitford, who found that the light from certain nebulae showed a progressive reddening with distance, over and above that caused by the red shift.

**Red Shifts.**—Further evidence for the island-universe hypothesis is given by the fact that the light from a typical nebula, resolved into its component colours with the aid of a spectrograph, is found to be very similar to that from stars within our own system; the similarity includes the pattern of absorption lines indicating the presence of hydrogen, calcium and other chemical elements in gaseous form. This result, first noted by J. Scheiner in 1899, was firmly established at the Lowell observatory in 1912 by V. M. Slipher, who interpreted the slight displacements of the absorption lines from their standard positions as a Doppler shift caused by a component of motion of the nebula along the line of sight (see SPECTROSCOPY, ASTRONOMICAL: *Radial Velocities*). Although the shift from a few of the nearer nebulae turned out to be toward the violet end of the spectrum, indicating a motion toward the observer, the overwhelming majority of the spectra Slipher examined during the succeeding years showed a shift toward the red, interpreted as a motion of recession. The velocities inferred from these shifts ranged up to 1,800 km. per second, far greater than the velocity of escape from the galaxy, thus furnishing additional support for the view that these nebulae were indeed independent systems. On comparing Slipher's red shifts with Hubble's distances, for nebulae common to the two lists, H. P. Robertson noted in 1928 that the data were consistent with a linear velocity-distance relationship, as had been foreshadowed on theoretical grounds about five years before by H. Weyl. This proportionality of velocity with distance was found independently in 1929 by Hubble, who extended it during the next few years to vastly greater distances with the aid of the magnificent red-shift measurements on faint nebulae by M. L. Humason at Mt. Wilson.

Recognizing the importance of this relation for cosmology, the Mt. Wilson and Lick observatories initiated in 1935 a program to explore the red shift as thoroughly and as deeply into space as modern instruments would permit; in 1952 the new equipment on

Palomar mountain was tied into this program. The results, comprising the measurement of red shifts on more than 800 different nebulae, were analyzed and published by M. L. Humason, N. U. Mayall and A. Sandage in 1955. Included in the survey were 44 faint cluster nebulae, whose red shifts indicated velocities of recession ranging up to one-fifth the velocity of light. On the basis of the new distance scale, the linear term (*i.e.*, the proportionality constant) in the velocity-distance relationship indicated that the velocity of distant nebulae increased 55 km. per second for each 1,000,000 light-years of distance from the earth. A better appreciation of the meaning of this number,  $H$ , which came to be called Hubble's constant, is given by its reciprocal  $1/H = 5,400,000,000$  years, interpretable as the time in the past at which all the nebulae would have started from a common spatial origin, provided the red shifts are taken to represent actual velocities which are directly away from the earth and which have not changed during the course of the motion. A most interesting fact revealed by the new investigation is that the red shifts of the faint cluster nebulae, extending out to a distance of 850,000,000 light-years, in fact increase faster with distance than would be implied by the linear law—as should be expected if the nebular motions are being slowed down by mutual gravitational attraction.

**Distribution of Nebulae.**—The Herschels' catalogues showed the nebulae to be distributed more or less at random over the sky, except for a conspicuous avoidance of the lower galactic latitudes. Succeeding surveys confirmed these observations and led to the conclusion that the nebulae are in fact scattered at random over the heavens, the apparent dearth in their numbers near the plane of the Milky Way being attributed to absorption of light by the dust clouds known on other grounds to be an important part of our own galaxy. This is not to say that there are no considerable irregularities in their apparent distribution; there is indeed a marked tendency to cluster in groups numbering from a few to more than a thousand members. One of the lesser examples of this clustering is the local group consisting of the galaxy itself, the Magellanic Clouds, the great nebulae in Andromeda and Triangulum and about a dozen others.

The apparent distribution over the sky, however, is only one aspect of the problem; it must be supplemented by an analysis of the actual distribution in depth. The material for this analysis is given by the extensive surveys to different apparent magnitudes carried out since 1920 at the Harvard, Lick and Mt. Wilson-Palomar observatories. This aspect of the problem is a much more difficult one, whose solution depends on the various distance criteria. It would appear from these criteria that, subject again to fluctuations associated with the clustering effect, the distribution in depth is also by and large a random one.

**The Nebular Universe.**—The study of the structure of our own galaxy has in some important respects lagged behind that of at least our nearer neighbours, a situation attributable in large measure to our position near the plane of the galaxy and to the obscuring matter lying between the earth and significant features of the system. This deficiency is to some extent rectified by the development of sophisticated methods of making allowances for the effects of the dust clouds on light coming to the earth from the stars, and by the rise of radio astronomy, which enables the mapping of hydrogen clouds in our galactic neighbourhood. The view which emerged in the middle 1950s was one in which the galaxy is itself a large spiral nebula, very similar in size, structure and content to Andromeda, one whose diameter is about 60,000 light-years and whose mass is that of about 200,000,000,000 suns. Nebulae as large as these are not uncommon, but the average is considerably smaller, with a mass of around 10,000,000,000 suns, including the mass of the dark clouds as well as that of the luminous matter.

The search for a fixed centre of the universe as a natural point of reference resulted in a shifting by stages from the geocentric position adopted by theology and early science to ever more distant objects, finally only to dissolve in the realization that there is no intrinsic distinction discernible between any one region of the nebular universe and any other. The planet earth was displaced by the sun, but it was then recognized that the sun was itself

but a relatively minor outlier of that great collection of stars whose nearer members were visible as the Milky Way. The development of the large telescopes in turn revealed hundreds of millions of systems comparable with our own, distributed more or less at random through a sphere whose radius is estimated in billions of light-years.

While the search for a preferred position, or even for a preferred direction, led to the realization of the macroscopic uniformity of the universe, it revealed on the other hand the existence of a preferred state of motion in each sufficiently large region of the nebular universe. Typical of the motions of individual stars within the galaxy is that of the sun, which moves at the cosmically modest speed of 150 mi. per second about the galactic centre, located 25,000 light-years away in the direction of the constellation Sagittarius. The relative motions of the nebulae within the local group hardly exceed this, and even in the giant clusters the relative motions rarely exceed 1,000 mi. per second. In contrast with these modest speeds are the ever-increasing velocities deduced from the red shifts of distant nebulae, which have been measured up to 38,000 mi. per second—a respectable fraction of the absolute standard of velocity, that of light. It would thus appear that in each sufficiently large region of space there exists a standard state of motion, from which the motions of individual nebulae differ by at most a fraction of 1% of the speed of light. It is to be noted that this apparent motion of the nebulae away from the galaxy does not in itself single it out as a unique centre from which everything else flees. For if the effect is due either to an attrition of light during its long journey or to an actual radial motion of the nebulae, the phenomena referred to any other nebula as the centre would appear the same.

## COSMOLOGICAL MODELS

The development of a more complete view of the universe unfolded by these observations requires an excursion into theory, in continuation of the process begun by Newton in extending to the far away and long ago the laws which have proved successful in ordering the here and now. The principles upon which modern science is based call for economy, in unproved hypotheses and *ad hoc* assumptions, in bringing new phenomena within the purview of its laws. Thus, since motion is the only hitherto known cause of the type of shift of spectral lines observed in the light from the nebulae, economy bids that it be tried as the effective cause here. Since gravitation is the only hitherto known universal action between macroscopic masses, principle bids that the laws of gravitational attraction, which have proved successful in ordering terrestrial, planetary and galactic motions, be extended to the nebulae. Since conservation of mass and energy has been an effective tool in ordering physical and chemical phenomena in the laboratory and in the stars, caution bids that it not be surrendered until the need to do so is quite definitely established. Strict adherence to these guide lines, however, has led to difficulties, particularly with respect to the time scale, and modifications of one or another of them have at times been proposed in order to bring prediction into agreement with observation.

Science progresses by paring a problem down, stripping it of all cumbrances judged not germane to the main issue. The result of the application of this method is a model which helps to explain the connections among the various elements of prime interest, which serves as a first approximation to the complex physical situation and which can be adjusted as required to trace the influence of those factors which have at first been set aside. In the present instance the elements which the model is to portray are the nebulae, treated as equal particles distributed uniformly throughout space, and the light which they emit, taken as obeying the smoothed-out velocity-distance relationship inferred from the empirical data; the laws to be applied are those governing the gravitational and electromagnetic fields.

**Cosmic Space and Time.**—The existence of a preferred state of motion in each sufficiently large neighbourhood of space-time makes it possible significantly to separate the four-dimensional world of events in the model into a three-dimensional cosmic space and a one-dimensional cosmic time. The nature of the

geometry of cosmic space is quite closely circumscribed by the assumption of spatial uniformity: from this it follows that the geometry must be either the flat Euclidean geometry of antiquity or one of the non-Euclidean geometries developed by Johann Bolyai, N. I. Lobachevski and G. F. B. Riemann in the first half of the 19th century. These latter geometries are characterized by a curvature  $K$ , which may be either positive or negative; the curvature may for convenience be written in the form  $k/R^2$ , where  $k = \pm 1$  indicates its sign and the radius of curvature  $R$  is a characteristic length. In the case  $k = +1$  space is said to be *closed*, as its total volume has the finite measure  $2\pi^2 R^3$  (or  $\pi^2 R^3$  if so-called antipodal points are identified). For  $k = -1$  space is *open*, having an infinite extent, as has also the flat Euclidean space  $k = 0$ . That physical space might turn out to be one of these non-Euclidean types, instead of the Euclidean space hitherto tacitly assumed in philosophy and science, was recognized from the time of their discovery. The first serious attempt to evaluate the curvature of astronomical space was made by K. Schwarzschild in 1900 on the basis of observations then available; he concluded that if space is open its radius of curvature  $R$  must be greater than 64 light-years, and that if closed  $R$  must exceed 1,600 light-years. (See GEOMETRY; *Non-Euclidean Geometry*; RELATIVITY; RIEMANNIAN GEOMETRY; SPACE-TIME.)

The cosmic space thus introduced is that collection of events having a common cosmic time  $t$ ; the geometry of successive spaces may therefore change with time, as foreseen by the philosopher A. Calinon in 1889. Under the present assumptions a cosmological model capable of representing the expanding universe of nebulae must in fact have a radius of curvature  $R(t)$ , i.e., an  $R$  which is a function of  $t$ —or in the Euclidean case a scale factor  $R(t)$ —which is now increasing with time in a manner prescribed by the law of the red shifts. The present value of the specific velocity  $\dot{R}/R$ , where  $\dot{R} = dR/dt$  is the time rate of change of  $R$ , must equal Hubble's constant  $H$ , and the specific acceleration  $\ddot{R}/R$  is determined by the deviations from linearity observed at great distances. The work of Humason, Mayall and Sandage implies a value of  $-2.6 H^2$  for the specific acceleration, where  $H$  is 55 km. per second per 1,000,000 light-years.

The problem of setting up a complete cosmological model thus reduces to that of determining the sign  $k$  of the curvature of cosmic space, and the course in cosmic time of its radius of curvature or scale factor  $R(t)$ . Observations such as those on the red shift give some information on the present value and trends of  $R$ , but in order to extrapolate from these to its behaviour in the past or future some form of physical law must be imposed. Present field theories of gravitation achieve this by relating the kinematics of the model to the physical content; that is, to the nature and amount of matter and energy found in that part of the universe accessible to observation.

Newtonian physics does not adapt itself to the cosmological problem, as formulated above, because of its inability to treat relatively accelerated nebulae as dynamically equivalent and to treat light in accordance with the principle of optical relativity. But even aside from this, the early efforts to describe an extended universe, uniformly populated with galaxies more or less at rest with respect to one another, ran into the difficulty that there existed no static solution of the gravitational field equations, or that such a solution was at best an uneasy equilibrium between indeterminate forces. A further difficulty was that of accounting for the comparative darkness of the night sky, for, as pointed out by H. W. M. Olbers in 1826, in a uniform distribution of stars the luminosity contributed by those within a spherical shell of given thickness should be independent of the radius of the shell. The total luminosity would accordingly build up to an intolerable magnitude, limited only by the absorption of light by intervening matter or by the exhaustion of the energy supply.

**General Relativistic Models.**—Interest in cosmology was stimulated by the realization that the spiral and elliptical nebulae were extragalactic objects, during just that decade (1911–20) in which the general theory of relativity was being developed. Already in 1917 Albert Einstein turned his attention to the cosmological problem, in an effort to establish E. Mach's hypothesis that

TIME-DENSITY RELATIONS IN RELATIVISTIC COSMOLOGY

the inertia of matter is due to the totality of other matter in the universe. Einstein found that, as in the Newtonian theory, his original field equations would not admit a static solution for the problem. He therefore modified his equations by the addition of a "cosmological term," characterized by a constant  $\Lambda$  having the physical dimensions of  $[time]^{-2}$ ; for positive  $\Lambda$  this in essence adds a repulsive force  $\Lambda R/3$  between the nebulae.

**Einstein Model.**—The addition of the cosmological term makes it possible to obtain a static model, of spatial curvature  $K = 4\pi G\rho_0/c^2$  determined by the mean density  $\rho_0$  of matter. Here  $G$  is the Newtonian constant of gravitation and  $c$  is the speed of light; the cosmological constant is given by  $\Lambda = c^2/R^2$ . For a mean density of  $10^{-29}$  g. per cubic centimetre, which is of the general order of magnitude to be expected if all matter were spread out uniformly, the radius of curvature of the universe would be 11,000,000,000 light-years. This solution of the cosmological problem offers little advantage over the classical, beyond eliminating the indeterminacy inherent in all open models. Subsequent investigation further showed that the static Einstein model is unstable; a slight relaxation of the assumed uniformity conditions will result in a collapse or a blowing up of the model.

**Lemaître-Eddington Model.**—Within the decade, however, the general expansion of the nebular universe came to be recognized and attention turned to dynamical solutions of the relativistic field equations as offering more suitable models. Among these solutions, first found by the Russian mathematician A. Friedmann in 1922, was one put forward by G. Lemaître (1927) and A. S. Eddington (1930) as representing an expanding nebular universe arising by perturbation from the unstable Einstein model. Its principal attraction lay, at a time when the inverse of Hubble's constant was considered to be less than 2,000,000,000 years, in the practically unlimited time scale the model offers. However, as in any model in which the repulsive cosmological force dominates the gravitational attraction, the specific acceleration  $\ddot{R}/R$  is positive, in conflict with the later red-shift data. Nor does it avoid Olbers' paradox mentioned above.

**De Sitter Model.**—All models in which  $\Lambda > 0$ , such as that of Lemaître and Eddington in which the cosmological term eventually

dominates, expand without limit toward a state in which the density of matter becomes negligible. This ideal limiting case is represented by a model based on a solution put forward, on other grounds, by W. de Sitter in 1917. In the simplest form suitable for the present purpose it is characterized by a Euclidean cosmic space provided with a distance scale  $R(t) = e^{Ht}$ , where  $e = 2.718$ ... is the base of the system of natural logarithms. The accelerated nebulae eventually escape over the observer's horizon, a sphere of radius  $c/H = 5,400,000,000$  light-years; light emitted by a nebula which has passed through this horizon will never reach the observer.

**Other Models Utilizing  $\Lambda$ .**—Einstein's original reasons for introducing the cosmological term, essential to the above models, are no longer considered valid, and he and others accordingly advocated its rejection. Its principal phenomenological function has been to extend the time scale implied by the nebular red shift, to allow time for such astronomical processes as the evolution of population II stars, believed to require about 5,000,000,000 years, and for the laying down of radioactive by-products found in terrestrial rocks and in meteorites, estimated to require up to 5,000,000,000 years. As such, it borders on those *ad hoc* hypotheses which good scientific methodology says to reject. But if the term is rejected there is still some trouble with the time scale, in spite of the upward revisions. Under these circumstances it would seem prudent provisionally to retain the cosmological term, and instead of seeking a definitive model, to display the range of models offered by the extended gravitational theory.

The choice offered is a threefold one, from which a particular model may be selected by specifying three independent data—say Hubble's constant  $H$ , the present mean density of matter  $\rho_0$  and the present epoch  $t_0$ . Taking  $1/H$  as 5,400,000,000 years, the general nature of those models which start from the singular state  $R = 0$  may be read off the accompanying figure, in which a point with abscissa  $\log \rho_0$  and ordinate  $t_0$  represents that model defined by these values of density and epoch; its position in the diagram indicates the signs of  $k$  and  $\Lambda$ , and whether the model is monotonically expanding (*i.e.*, expanding independently of  $H$ ,  $\rho_0$  and  $t_0$ ) or oscillating. To adjust the diagram to any other value of  $1/H$ , it is necessary only to slide the abscissa scale a distance  $2 \log f$  to the right and to multiply the ordinate scale numbers by  $f$ . All these models avoid Olbers' paradox almost trivially—there simply has not been time enough for the luminosity to build up indefinitely, and it is further reduced by the weakening effect of the red shift. Two models of passing interest, in which the cosmological constant  $\Lambda$  is set equal to zero, are the following:

**Einstein-De Sitter Model.**—In this model, a special case of the Friedmann solution singled out by Einstein and De Sitter in 1932, space is taken as Euclidean; it is represented in the diagram by the point of intersection of the two curves along which  $\Lambda$  and  $k$  vanish, respectively. The present epoch is 3,600,000,000 years and the present mean density  $6.2 \times 10^{-29}$  g. per cubic centimetre. The radius of curvature  $R$  varies with  $t^{2/3}$ —and consequently  $\dot{R}/R$  is positive, in conflict with the red-shift data.

**Friedmann Model.**—Demanding that the model also fit the second order red-shift data amassed by Humason, Mayall and Sandage shoves the representative point farther down on the curve  $\Lambda = 0$  to the point F on the diagram. The resulting model is a closed, oscillating one with the improbably low age of 2,400,000,000 years and the high density of  $3.2 \times 10^{-28}$  g. per cubic centimetre. The gravitational retardation would bring the motion to a halt in a further 2,700,000,000 years, when contraction would set in.

All the models so far considered have been based on the tacit assumption that the density of radiant energy in the universe is negligible in comparison with that of matter. Although this assumption is justifiable in the present state, since the former is perhaps only 1% of the latter, this may well not have been true in the very early stages. This circumstance was exploited by G. Gamow in his theory of the formation of chemical elements and of protogalaxies during the early stages of the expansion (see COSMOGENY).

**Steady-State Theory.**—The only expanding cosmological model satisfying the additional requirement that the intrinsic structure of space-time be independent of cosmic time is that described above as de Sitter's. This was adopted as the background of a steady-state theory of cosmology by the British group associated with H. Bondi, T. Gold and F. Hoyle. But whereas the de Sitter model is empty of matter when treated in accordance with Einstein's general theory of relativity, matter is introduced in the steady-state theory, and in view of the expansion must be assumed to spring into being uniformly throughout space at just the rate necessary to replace the continuing loss of nebulae over the observer's horizon. The age of the universe itself is therefore infinite, but the age of each bit of matter in it is finite and is at any given time on the average just equal to  $1/3H$ , or 1,800,000,000 years. This theory is subject to direct observational test, as it predicts that in any sufficiently large region of space nebulae are found in every stage of development and that there should be no systematic change with distance.

**COSSA, FRANCESCO (DEL)** (1436–1478), Italian painter who, through his seven years' residence in Bologna, exercised a profound influence on the course of Bolognese painting, was born at Ferrara. His name first occurs in a contract for a "Pietà" on the choir screen of Ferrara Cathedral. In 1472, in Bologna, he was commissioned by Giovanni Bentivoglio to restore and complete a fresco by Lippo di Dalmasio in Sta. Maria del Baraccano. Immediately after (1474) he painted an altarpiece for the Foro della Mercanzia (now in the Pinacoteca Nazionale, Bologna). He died at Bologna in 1478, while working on the frescoes of the Garganelli Chapel in S. Pietro.

Cossa was influenced by the work of Andrea Mantegna and by Piero della Francesca, as well by the cursive drawing style of local illuminators. His debt to Piero is most clearly apparent in a painting of Autumn in the Kaiser Friedrich Museum, Berlin. Other early works reflect the influence of Florentine art ("Virgin and Child with Angels" in the National Gallery of Art, Washington) and Rogier van der Weyden, who was in Ferrara in 1450 ("Pietà" in the Musée Jacquemart-André, Paris). In the frescoes in the Palazzo Schifanoia, Ferrara, probably commissioned in 1469, Cossa develops a personal style of great coherence and vitality. Illustrating a humanist program, they represent in three tiers allegorical scenes, astrological symbols of the months, and scenes representing the daily life of the ruler of Ferrara, Borso d'Este. Cossa was solely responsible for the frescoes on the east wall representing March, April, and May. The *salone* of the Palazzo Schifanoia ranks among the most striking examples of Renaissance secular decoration.

In or after 1470 Cossa began work on an altarpiece of the Annunciation for the Osservanza at Bologna (now in the Gemäldegalerie, Dresden). A second polyptych of the same date, painted for the Griffoni altar in S. Petronio at Bologna (frame commissioned 1473), has been disassembled. The lateral panels, now in the Brera Gallery, Milan, in which the saints are depicted on rocky platforms against low distant landscapes, are Cossa's most successful panel paintings. Among Cossa's last works in Bologna was the cartoon for a circular stained glass window of St. John on Patmos in S. Giovanni in Monte.

**COSSACKS.** The Turkic word *kazak* means "adventurer" or "rebel"—figuratively a "free man." This name was first given in the middle ages to the fugitives from the central Asian Turkic states who preferred a nomadic life in the steppes north of the Black sea to serfdom. Later, when Poland ruled the western part of what is now the Ukraine, the same phenomenon occurred and the same name was applied to the peasants who were escaping from

their landlords "beyond the cataracts" (*za porohy*) on the lower Dnieper. Thus, in a no-man's-land, was born the *Zaporizhska Sich* or Zaporozhian clearing—an embryo of the Ukrainian state. By extension, all peasants of the southeastern borderland of Poland, or *ukraina*, became known as Cossacks (Pol. *kozacy*). The Ukrainians, therefore, were first known as Cossacks, but not all the Cossacks were Ukrainians; many of them belonged to the Turkic peoples, many were of mixed races.

At the beginning of the 16th century, to protect their states against the incursions of the Tatars, the Polish kings started to organize military Cossack-manned frontier forces. Bohdan Chmielnicki (*q.v.*), however, himself a Pole, succeeded in setting up a practically independent Cossack state for a short time. In mid-17th century, when the Ukraine was partitioned between Poland and Russia, the Russian tsars followed the Polish example on a much larger scale in using their Cossacks (Russ. *kazaki*) first as border defenders and later as advance guards for the extension of Russia beyond the Urals, the Caucasus and the Caspian sea. Ermak Timofeevich, the conqueror of Siberia, was a Cossack. When the tsars or local landlords tried to reduce their freedoms, the Cossacks often revolted. The most famous rebels of the 17th and 18th centuries—Stenka Razin (*q.v.*), Kondrati Bulavin and Emelyan Pugachev (*q.v.*)—all came from the ranks of the *kazachestvo*. In international affairs the most important Cossack leader was Ivan Stepanovich Mazepa (*q.v.*).

The Cossacks were endowed with certain privileges and bound in return to give military service, which was compulsory for all men for 20 years, beginning with the age of 18. The primary unit of the Cossack community was the *stanitsa*, or village. Every *stanitsa* had an elected assembly. The *stanitsy* were grouped in *okrugi* (districts) and a number of those formed the *voisko* (army) headed by an *ataman* or hetman appointed by the central government. The land was held by the village as a commune, but from 1869 Cossack officers and civil servants were allowed to acquire land as personal property. In addition both the officers and the communes were permitted to rent their land to outsiders. Thus already existing social distinctions deepened.

At the beginning of the 20th century there were in Russia 12 Cossack *voiska* (see table). The total area of the Cossack territories was about 230,000 sq.mi. with a total population of about 12,000,000, of whom more than 5,000,000 possessed special Cossack status. In peacetime about 55,000 Cossacks were under arms, in wartime about 180,000.

*Cossack Voiska in Russia at the Beginning of the 20th Century*

<i>Voisko</i>	Headquarters	Cossacks	<i>Voisko</i>	Headquarters	Cossacks
Don	Novocherkassk	1,500,000	Siberia	Omsk	180,000
Kuban	Ekaterinodar*	1,350,000	Amur	Blagoveshchensk	50,000
Ural	Uralsk	900,000	Semirechye	Verny†	45,000
Orenburg	Orenburg	530,000	Astrakhan	Astrakhan	40,000

Transbaikal	Chita	270,000	Yenisei	Irkutsk	30,000

\*Now Krasnodar. †Now Ordzhonikidze. ‡Now Alma Ata.

During the Russian civil war of 1918–20 the Cossacks were divided and fought on both sides. In the campaign against Poland in 1920 Red Cossack units under S. M. Budenny played a considerable part. On the collapse of the Russian "White" armies about 30,000 Cossacks went abroad. Some Cossack units were also revived during World War II, but their old communities were dissolved and merged into new administrative divisions of the U.S.S.R.

There exists a great deal of literature describing the spirited Cossack life. Among novels N. V. Gogol's *Taras Bulba*, Lev N. Tolstoi's *Kazaki* and H. Sienkiewicz's *Ogniem i mieczem* ("With Fire and Sword") are the most famous.

**COSTA, LORENZO** (c. 1460–1535), painter of the school of Ferrara-Bologna, was born at Ferrara and was trained there, prob-

ably under Cosimo Tura. From at least 1485 he worked at Bologna, latterly in close connection with Francia, whose mild and sleepy style led him to eliminate his native robustness. His best works are several altarpieces which remain in the churches of Bologna.

In 1506, soon after the expulsion of the Bentivoglio family from Bologna, he was summoned as court painter to Mantua to succeed Andrea Mantegna. He had already painted (1504–06) one elaborate allegory for the marchioness of Mantua (now, with its companion, in the Louvre) and spent his last years in the service of the Gonzagas doing religious and historical pictures, but few survive.

Costa died at Mantua on March 5, 1535.

See Giorgio Vasari, *Vita di Lorenzo Costa*, ed. by A. Stanghellini (1912). (E. K. We.)

**COSTA BRAVA CATALANA**, the "rugged coast" of Catalonia, northeastern Spain, lies between the French frontier at Port Bou and Blanes, 66 km. (41 mi.) up the coast from Barcelona. It is in the province of Gerona (*q.v.*). This part of the Spanish coast, almost unknown to tourists until after World War II, subsequently became very popular—the fishing village of Lloret de Mar possessed more than 100 hotels in the 1960s. The attraction of the Costa Brava largely results from the grandeur of the coast line and the warm seas, but even at the height of summer the evenings are comparatively cool because of the proximity of the Pyrenees. The average mean temperature in winter (November–March) is 57° F. and in summer (April–October) 74° F. The mimosa and spring flowers are in bloom from January onward and subtropical plants also flourish. Agriculturally the area is one of the richest in Spain, and it is also the most important cork-growing region, supplying the wine-producing areas of the world. The Costa Brava can be reached by train from Port Bou or Barcelona or by car via the coast road at Port Bou or the mountain pass between Le Perthus (France) and La Junquera. (D. F. H.)

**COST ACCOUNTING.** This term includes the entire range of theories, methods and procedures for accumulating, measuring and reporting the cost of obtaining specific objectives. The theoretical framework of cost accounting is borrowed from political economy and the methods are adapted from financial accounting and statistics. The boundaries of the field are not clearly defined; its content is shared with management, engineering, economics, financial accounting and more recently with operations research and the behavioural sciences. (See also MANAGEMENT SCIENCES.)

An understanding of the work of cost accountants requires some understanding of the nature of general accounting (*q.v.*). The usual meaning of "to account" connotes an objective and a responsibility for measuring and reporting the extent of accomplishment of the objective. The forms and reports of accounting tend to reflect the types of accountabilities involved. Simple score-keeping in a game, for example, accounts for and reports winners, losers and individual performances. Accounting for bailee activities is related to the function of safeguarding and locating physical properties. Ordinary business accounting is concerned with the more complex objectives of liquidity, profitability and efficiency.

In cost accounting the primary objective is to measure and report actual sacrifice—effort exerted in terms of cost—and projecting acceptable standards of sacrifice for accomplishing specific goals. The consumer who is deciding to allocate more of his limited resources for transportation and less for shelter is comparing benefit in terms of sacrifice. Similarly the worker who compares additional leisure obtained by working fewer hours with the probable decrease in income is utilizing cost accounting techniques.

Accountants are not able to attack the problem of individual sacrifice on the psychic level except through somewhat artificial techniques and have therefore adopted the practice of measuring and expressing effort exerted in monetary terms. This practice sometimes leads to difficulties. For example, in times of changing price levels historical costs lose their relationship to sacrifice in current terms. To fail to modify the historical cost figures and

revise the measuring unit may lead to unsound decisions. Furthermore, there are often substantial differences between cost to a business enterprise and cost to society; minimum enterprise cost may not lead to minimum social cost. The costs to society of a dingy manufacturing neighbourhood, for example, seldom appear in private accounting records.

Further assumptions limit the field of cost accounting to an even more restricted list of activities and techniques. Accountability for costs is usually restricted to a specific area of interest and costs are related to the activities of those who are responsible for attaining the objectives of the organization. Departments are established to correspond with areas of authority and responsibility, and cost centres are set up within departments to help record costs by activities. Activity is sometimes represented by operations, tasks and time periods, or by units of production. For example, the activity unit for measuring costs may be the labour or machine hour, the space-time unit, the customer call, the ton delivered, the invoice rendered or the unit machined. If the costs are accumulated by periods with respect to similar units of output, and departments and centres are established to determine the cost of each major process or activity, the system is known as process costing. If costs are accumulated with respect to jobs or diverse products, the system is a job-order cost system.

Accounting for costs may take the form of routine day to day accumulating and periodic reporting or the form of cost studies for special purposes when the need arises. The former approach coincides with the narrow definition of cost accounting and is used when objectives are stable and managerial decisions require only periodic reports of accomplishments and costs. Traditionally, cost accountants have simplified their routine costing by avoiding imputations and hypothetical charges and including among routine day to day costs only those sacrifices that involve expenditures, other assets given up at fair market values or capital stock issued at current value. Economists, engineers and some accountants have encouraged the inclusion of imputed costs—interest, profits, rents and salaries—but the prevailing attitude has been to exclude these items from day to day costing and to add supplementary reports with imputations on an intermittent basis when specific decisions require them. Such supplementary reports include economy studies for asset exchanges, plant shutdown or expansion and the selection of lot sizes. Clearly alternatives foregone (opportunity costs) are directly relevant to these problems and direct imputations cannot be avoided.

The assignment of cost to activities requires analysis to determine whether changes in costs can be associated with changes in activity. This associative approach to cost allocation with its assumption of responsibility is the primary basis for assignment and is necessary for making decisions about output and prices. If an activity is clearly associated with the decline in service value of an asset and receives the benefit of such service the cost is said to be direct. Thus, direct labour and materials in a machine shop can be traced to activities directly on a responsibility basis, and the cost of a library building may be said to be direct with regard to the library department. It is ordinarily not feasible to trace all responsibility costs directly, and therefore several smaller variable costs are often lumped together and assigned to an activity by means of a combined variable rate or even through the general overhead rate.

It is difficult to assign all costs on the basis of direct short-run responsibility. For example, considerable sacrifice is necessary to keep an establishment ready to do business. These costs are often common to all departments and seldom vary with changes in the production rate. These fixed establishment costs may change in amount from period to period but the variation in a fixed cost must be independent of the activity under consideration. Some fixed costs, such as general supervision, are common to all activities. Other fixed costs, such as the cost of shelter for the machine shop, are direct with regard to the total activity of machining but are indirect with respect to individual jobs or specific machining activities. As a rule, fixed costs are common to several activities and do not vary with the rate of production.

There is disagreement in the cost accounting profession and among economists and engineers about the need for assigning common costs to activities and jobs. To those who advocate direct (marginal) costing the assignment of establishment costs except as a deduction from periodic revenues serves no decision-making purpose and may obscure relevant information for short-run decisions on prices and output. Other accountants favour the "full costing" approach and feel that such assignments give a better guide to long-run cost of production, to expansion and contraction problems, and, when combined with marginal costs, to more effective short-run pricing and output decisions. The usual cost accounting standard for assigning fixed overhead costs is the basis of relative benefit. Shelter cost, for example, is usually distributed under the assumption that benefit can be approximated by a space-time factor, and assignment to a job or activity is in accordance with space-time utilized. Supervision may be allocated on the assumption that benefit is proportional to the number of men or man-hours supervised. This and similar costs are sometimes assigned on the basis of time studies and the relative time spent is assumed to be an acceptable approximation of relative benefit. The justification for fixed cost assignment according to benefit is clear if individuals are involved and equitable billing is an objective. In addition, the benefit distribution sometimes serves as a crude approximation of long-run responsibility and as an imperfect expression of scarce-factor utilization.

**Control of Costs.**—Cost accounting and related performance budgeting are useful for income determination, inventory valuation and pricing, but it is generally conceded that their greatest contribution is in the area of cost control. Standard costs have implications of normative behaviour and indicate what the sacrifice ought to be to accomplish organizational objectives. Actual costs are accumulated for each activity and variations between standard or allowed cost of accomplishment and actual cost are brought to the attention of the management for investigation and possible remedial action. Careful preliminary studies and even modification of the organizational structure are usually necessary to locate and fix personal authority so that the responsibility for variances may be assigned and investigated. Major variances such as those for the cost of materials, materials usage, labour effectiveness, wage rates, idle or excess capacity, departmental operating efficiency and overhead budget management are often isolated in separate accounts with appropriate details shown in supporting statistical exhibits. In a few cases variances are presented and analyzed statistically with no standards or variances shown in the formal accounts.

The determination of standards for prices, usage, activity and efficiency is a delicate job that often requires the co-operative effort of time-and-motion experts, production and personnel men, psychologists, engineers, statisticians, accountants and perhaps other specialists. Some managers still insist on ideal standards with chronically unfavourable variances, but most psychologists feel that standards should represent attainable goals that can be reached by efficient performance. There is some disagreement on the need for frequent changes in standards between those who use currently attainable performance levels and those who use basic standards with supplementary analysis to account for intervening price and technological changes. A few engineers and accountants feel that the reduction of certain variances (e.g., efficiency and idleness) to monetary units serves no purpose.

Standards are by no means the only weapons for control. Cost accountants usually install invoice and voucher techniques that encourage the prompt, accurate and efficient payment of obligations. Timekeeping and payroll devices are used to assure management that workers are actually on the job and are being paid according to wage agreements. Devices to assure adequate quantities of materials and to disclose shortages and excesses of materials, tools and machines come under the cost accountant's jurisdiction. The techniques of flexible performance budgeting and related charting are also considered to be a part of cost accounting. The responsibility for issuing orders to initiate more effective control is, of course, a responsibility of management, but sometimes authority to correct minor irregularities is delegated to

cost accountants and budget masters.

**Historical Development.**—The origin of cost accounting, along with the origin of bookkeeping itself, is unknown. Attempts to keep manufacturing accounts have been traced to the time of Henry VII and to the Medici. The account books of Christophe Plantin, a French publisher, showed some understanding of job-cost accounting before the 16th century. Manuals for double-entry bookkeeping before the 19th century were common, but little or no mention was made of manufacturing or costing methods until Charles Babbage in England (approximately 1830) presented a paper that emphasized the need for serious cost accounting. The French, led by Anselme Pagen and Louis Mézières, were active in the early part of the 19th century and in 1841 Armand Malo won a prize of 1,000 fr. for his manual of agricultural accounting for primary schools.

In the period from 1870 to 1900 engineers took the lead in developing cost accounting methods and in 1900 Alexander Hamilton Church, president of the Institute of Cost and Works Accountants, set forth the modern approach to production centres and idle capacity charges. Fixed-variable analysis of business costs is credited to Dionysius Lardner (1850) and was developed in France by C. Adolphe Guilbault about 1865, in Great Britain by John Manger Fells (1877) and Alfred Marshall (1890), and in Germany by Eugen Schmalenbach (1900). Attempts to set and use standards were made in the textile industry by G. P. Norton (1889), but developed standards date from F. W. Taylor (*Shop Management*, 1903), John Whitmore (1908), and Harrington Emerson (1909). Profit charts and modern flexible budgeting were presented by Fells in 1903.

It is generally conceded that the structure of modern factory cost accounting was established before World War I. Beginning about 1930 businessmen and economists became impressed with the magnitude of the costs of distribution and cost accountants therefore began to extend their factory techniques to cover the control of distribution activities. Costs are accumulated and compared for size of order, method of delivery, line of distribution, customer call, ton warehoused and a myriad of office activities.

The investigations of the Federal Trade commission and the passage of the Robinson-Patman act in the United States accelerated the development of distribution cost methods by insisting that differences in selling prices over a large segment of business activity be justified in terms of differences in costs. Toward the middle of the 20th century, retail stores developed expense-centre accounting, which is a highly developed method of determining the cost of merchandising activities, and they extended the older retail accounting to a more comprehensive fixed-variable structure by developing merchandise management accounting.

During World War II emphasis on cost control was reduced, and temporarily attention returned to the older objective of compilation for billing purposes. Postwar competition, however, led to a rapid return to cost control and to the birth of managerial accounting with renewed emphasis on enterprise goals and accomplishments.

The extension of cost accounting techniques and principles to governmental units in the United States was a development of the middle of the 20th century. Difficulties arose with regard to the measurement of certain governmental and institutional services, and unfortunately many costs exhibited erratic behaviour. Many institutions and governmental units that were using budgets primarily as expenditure controls installed performance budgeting, which combines financial controls with standard costing. Many school systems, universities, hospitals and clubs rapidly adopted similar types of performance budgeting. The problem of costing has been studied by the government in Great Britain, particularly in relation to the cost of medical services.

The growth of uniform cost systems has been comparatively rapid even outside the totalitarian countries where uniform methods of costing are necessary for effective over-all planning. In the United States uniform costing has been sponsored by trade associations, which collect reports and compile statistical measures

that serve as norms against which each member firm can appraise its performance. These associations have been active in recommending specific cost systems for their members and have carried on educational work designed to impress their members with the importance of knowing production and distribution costs for intelligent pricing and effective control. European productivity teams have repeatedly expressed their surprise at the interest in costs shown by U.S. businessmen, and the display of competitive spirit directed toward bringing their costs within budgeted standards or below those reported by their competitors.

The professional status of cost accounting is encouraged by organizations such as the National Association of Accountants, Controllers Institute of America, Institute of Cost and Works Accountants, Society of Industrial and Cost Accountants of Canada and similar groups.

**COSTA MESA**, a city of Orange county, Calif., U.S., is located on a bluff overlooking the Pacific ocean, 40 mi. S.E. of Los Angeles. It was incorporated in 1953. Originally an agricultural area and the location for the Santa Ana army air base during World War II, its growth was due largely to the availability of land for light industries, of which 140 are located within the city limits. Industries include electronics, boatbuilding, machine tools and the fabrication of articles of fibreglass, such as fishing rods. The construction of freeways reduced driving time to Los Angeles and stimulated residential expansion. Costa Mesa is the site of the Orange County fair and the seat of Southern California college (Assemblies of God), founded in 1920, and Orange Coast college, a public junior college, founded in 1947, with a full-time enrollment of over 3,000 on a 243-ac. campus. For comparative population figures see table in CALIFORNIA: Population.

(G. T. Br.)

**COSTA RICA**, a republic of Central America lying between Nicaragua and Panama. Its land area of 19,652 sq.mi. makes it the second smallest country in Central America (next to El Salvador). Its population in the late 1960s was estimated at about 1,500,000.

Costa Rica (literally "rich coast") is known in the markets of the world chiefly for the high quality of its coffee. Costa Ricans also take pride in their country's achievements in education and in the practice of democratic government. The nation's capital and largest city, San José (q.v.), had a population of more than 100,000 in the late 1960s.

## 1. PHYSICAL GEOGRAPHY

**1. Geology.**—The higher parts of Costa Rica's two largest peninsulas, Osa and Nicoya, are complex Mesozoic metamorphic rocks. The lower parts of these peninsulas and the coastal range in the southwest, the upper Río Diquis (Río de Térraba) basin and the Pacific lowlands consist of Oligocene sandstones and limestones with much volcanic ash overlain in places with recent alluvium. In northwestern Costa Rica is the narrow Cordillera Volcánica (Miocene volcanic range, flanked by Miocene marine sediments with much volcanic materials), with several dormant volcanoes ranging in height from 4,500 ft. to the highest, Miravalles, 6,627 ft. In southeastern Costa Rica is the wide Cordillera de Talamanca. It consists of precretaceous granite and metamorphic rocks, flanked on both sides by Miocene and Oligocene conglomerates, shales, sandstones and admixtures of volcanic materials, and is cut by many porphyritic dikes. It has no low passes and its highest peak, Chirripó Grande, is 12,533 ft. The Cordillera Central has several high Tertiary volcanoes, largely dormant: Poás (8,875 ft.), Barba (9,533 ft.), Turrialba (10,919 ft.) and Irazú (11,260 ft.). In March 1963 Irazú erupted for the first time in decades, destroying crops and killing livestock on the central plateau. Although many thatched homes caved in, no persons lost their lives. West of the Cordillera Central is the Meseta Central, an intrusive cretaceous granite tableland, deeply mantled with volcanic ash. The foothills and lowlands of north-eastern Costa Rica consist of Oligocene-Miocene sandstones, shales and limestones, and recent alluvial deposits.

**2. Relief and Drainage.**—The Caribbean coastal plain, from 2 to 5 mi. wide in the south and 70 mi. wide in the extreme north, is level and poorly drained near the coast. It makes up about one-fourth of Costa Rica's land area. Several large rivers cross these plains and empty into the Caribbean. The Sixaola for part of its course forms the international boundary with Nicaragua. The Reventazón rises on Irazú volcano and drains the eastern

part of the Meseta Central before turning east toward the Caribbean; its valley constitutes the only railway and highway route from the Caribbean lowlands to the Meseta Central. The Chirripó also rises on Irazú volcano and joins the Colorado river, one of the mouths of the San Juan. The Arenal-San Carlos rises in Lake Arenal west of the Cordillera Volcánica and empties into the San Juan. Only the San Juan, which for part of its course forms the international boundary, is navigable. The three cordilleras are very rugged, but their slopes descend within a few miles to low foothills and plains. The Meseta Central is rolling. On the west coast the Osa and Nicoya peninsulas, the coastal range and the upper Grande de Térraba river basin are hilly. The Pacific and broad Guanacaste plains are level and for the most part well drained. The large rivers emptying into the Pacific are the Grande de Térraba, Grande de Tárcoles, which drains the western part of the Meseta Central, and the Tempisque and Bebedero, which drain the Guanacaste lowland.

**3. Climate.**—Areas below 3,000 ft. have mean annual temperatures of about 80° F., with little monthly variation from the annual averages but with diurnal ranges of 15° F. or more. Mean annual temperatures decrease from about 74° F. at 3,000 ft. to 59° F. at 5,000 ft.; the mean annual temperature at San José (altitude 3,806 ft.) is 67°, with extremes of 47° minimum and 94° maximum. Above 5,000 ft. mean temperature ranges are 57° to 41°, with frosts occurring in several months; this altitude zone is known as *tierra fría* ("cold land"). Precipitation varies greatly with elevation and exposure to the northeast trade winds. East of the continental divide rainfall is heavy; in some areas the mean annual rainfall exceeds 200 in. No month has less than six inches and rain may fall on more than 260 days per year. West of the divide rainfall is less; at San José in the Meseta Central the mean annual rainfall is 71 in., with each month from December to April receiving less than 2 in.; the northwestern plains and hills get from 50 to 80 in., with five months very dry;

and the southwestern plains and mountain slopes have from 80 to 130 in., with three very dry months.

**4. Vegetation.**—The natural vegetation of Costa Rica includes five types of forests and three types of grasslands. Two forest types are minor: species of palms in fresh-water and brackish swamps along the Caribbean coast, and broad belts of mangroves along the Pacific shore and tidal streams. Broadleaf evergreen forests cover 60% of the country; less than 3% has been cleared for agriculture (principally banana lands) and for forest products. The evergreens grow in areas that are rainy all year—west of the palm swamps to about 6,500 ft. and on intermediate slopes on the west side of Cordillera de Talamanca to the shores of Osa peninsula. This forested area contains more than 1,000 species, of which 200 grow to heights of 70 ft. or more; they include mahogany, Spanish cedar, *lignum vitae*, balsa, rosewood, ceiba, nispero, zapote, Castilla rubber, brazilwood and others. Between this forest and about 10,000 ft. on the Cordilleras Central and de Talamanca are mountain rain forests dominated by large oaks with unimportant admixtures of other species. The high peaks of these cordilleras are covered with *páramos*, or alpine grasslands, consisting of mats of scrubby plants, sphagnum moss, blueberries and other plants of the Ericaceae. Broadleaf deciduous open oak woodlands and temperate grasslands once occupied the Meseta Central but it is now largely devoted to crops and pasture. Northwestern lowlands and hills, with a long dry season, have patches of deciduous tropical forests and large savannas. Common drug and medicinal plants are ipecac, arnica, copaiba, camomile, wormseed and tamarind.

**5. Animal Life.**—Native animal life is abundant. Deer, squirrel, opossum, tapir and porcupine are present in many areas. There are many species of reptiles: crocodiles, lizards (giant iguana and others), snakes and turtles. Rodents include agoutis, rats and mice. There are numerous species of water and land birds,

many beautifully coloured; and many species of insects, most of them with varied protective coloration. Fresh-water and salt-water fish and mollusks are abundant; tuna, swordfish, marlin, dolphin, shark and others are caught in Pacific coastal waters.

## II. GEOGRAPHICAL REGIONS

Costa Rica may be divided into four distinct geographical regions: (1) the Caribbean lowlands; (2) the highlands; (3) the plains of Guanacaste and northern Puntarenas provinces and the hilly land of the Nicoya peninsula; and (4) the southwestern plains and the Osa peninsula, coastal range and upper Grande de Térraba basin. The Caribbean lowlands, narrow in the south and wide in the north, hot and rainy all year, are densely forested, except where they have been cleared for farm land along the railway lines inland from Limón. Embracing one-fourth of the national area, these lowlands have only 6% of the country's population. The inhabitants live in scattered lumbering camps and along railway lines in former banana districts that now grow cacao, abacá, rubber, corn, yucca, fruits and other foodstuffs.

The highlands, relatively narrow in the northwest, but wide in the central and southeastern parts, consist of the Cordilleras Volcánica, Central and de Talamanca and the Meseta Central. The rugged, rainy and forested Cordillera Volcánica is sparsely settled. The high, rugged, rainy, cold, and mostly forested Cordillera de Talamanca is very sparsely settled. The Meseta Central at an altitude of from 3,000 to 4,500 ft., the southwestern volcanic slopes of Cordillera Central and the Upper Turrialba and other valleys have 70% of the population of Costa Rica and all the large cities. Its population is mostly white, of Spanish descent. This small region is the economic, cultural and political heart of the country. The region has much rolling well-drained land, productive soils derived from lavas and volcanic ash, pleasant subtropical temperatures, an annual rainfall of 60 to 75 in., of which about 70% falls from May to November, and sunny dry weather from December to April. It has all but about 17% of the nation's improved highways and has direct access to both coasts—by railway to the Caribbean at Limón and by railway and modern highway to the Pacific at Puntarenas. It produces all the coffee grown in Costa Rica and most of the tobacco, onions, tomatoes, potatoes, corn, beans, sugar, pineapples, oranges and dairy products. It has half the country's cattle, swine and poultry and produces most of the manufactured goods.

The plains of Guanacaste and northern Puntarenas provinces and the hilly land of the Nicoya peninsula, in places moderately densely settled, have about 15% of the country's population. The annual precipitation of from 50 to 80 in. is the least received anywhere in Costa Rica and the dry season in this area is longest and most pronounced. Nevertheless, this region is important agriculturally. More than half the country's beef cattle, marketed chiefly in highland cities, graze on natural savanna and planted pastures in this area. The region also supplies significant quantities of rice, sugar, corn, beans, sesame seed and products from the considerable remaining stands of broadleaf deciduous forests. In addition, Pacific waters contribute most of the fish taken in Costa Rica.

Southwestern Costa Rica has about 9% of the country's population. This population is located chiefly in the Pirris, Paquita and Naranjo valleys near the coast in central Puntarenas province, and in the lower Grande de Térraba and Coto plains in southern Puntarenas. When the banana plantations in Caribbean lowlands in the early 1930s went out of production because of the Panama disease, plantations were established in the first group of valleys. However, these valleys now produce chiefly African oil palms, rice, cacao and corn. Nearly all the bananas exported from Costa Rica come from new plantations in the Grande de Térraba and Coto plains. The upper Diquis basin, the Osa peninsula and the coastal range are rainy nearly all year, are covered with broadleaf evergreen forests and are largely uninhabited. However, the Inter-American highway, crossing the upper Grande de Térraba basin from the southeastern corner of San José province to Panamá, opened up areas for settlement and development.

### III. THE PEOPLE

**1. Ethnic Character.**—Their ethnic background is relatively homogeneous. It has been estimated that 97.6% of Costa Ricans are either white or mestizo. Nearly all Costa Ricans boast some Indian ancestry in the remote past, but the Spanish heritage predominates because the original Indian population was scattered and small. The early Spanish settlers came largely from the Estremadura and Andalusia districts and were later supplemented by immigrants from Castile. The Indians, estimated at about 4,000 in 1956, live in remote mountain districts. Negroes are also few—perhaps 2% of the population—and live chiefly in the coastal banana-producing regions.

**2. Languages.**—Except for the Indians, all Costa Ricans speak Spanish. French, long the second language of educated Costa Ricans, is rapidly being replaced by English. Because of their use of diminutives, such as *chiquitico* for *chiquito*, the Costa Ricans are called "Ticos" by their Central American neighbours.

**3. Religion.**—Ninety per cent of the Costa Ricans are affiliated, though in many cases only nominally, with the Roman Catholic Church. The virtual extermination of the Indians kept the practice of Catholicism free of Indian rites and folklore. Priests are few in proportion to the population, and relatively few are native Costa Ricans; many are German, Spanish or Italian. Protestant missions are active but have made relatively few converts.

**4. Customs and Culture.**—The culture of the Costa Ricans, like their racial background, is relatively homogeneous. The basic Spanish Catholic pattern, developed into a peculiarly national one during centuries of comparative isolation, persists in spite of changes brought about by contacts with German planters and priests, French, Belgian and North American teachers, and foreign goods and motion pictures. This basic pattern is evident in the great importance attached to family ties, in sedate, ritualized conventional behaviour, and in the yearly round of festivals, such as the colourful and solemn Holy Week processions.

Although folk arts and crafts are not highly developed, one picturesque element of rural culture is peculiarly Costa Rican: the oxcart, its solid wooden wheels and sides gaily painted in elaborate designs. The custom of the *retreta* is also typical of Costa Rica. While a band plays classical and light music in the central square of the town, boys and men stroll around the square in twos and threes in one direction, girls and women in the other.

Joining a girl for a stroll around the square signifies romantic interest.

Mass and market on Sundays are the high point of the country dweller's week, the coffee harvest and the festival of the patron saint of each village the high point of his year. City and country dwellers alike enjoy lotteries and games of chance at their fairs and festivals. Soccer is the national sport. Movies, dancing and a "carnival" or civic celebration at year's end, with bullbaiting as one of its chief attractions, are the chief urban diversions.

The Costa Rican diet, like that of other Latin-American countries, is based on Indian and Spanish-colonial staples: *tortillas* and plantains, rice and black beans. (Jo. B. B.)

### IV. HISTORY

**1. Discovery and Early History.**—Costa Rica was discovered and probably named by Christopher Columbus, on his fourth and last voyage to America. On the Caribbean shore of Costa Rica the Spaniards found the first traces of the gold they sought in the earrings and other ornaments of gold worn by the natives. These ornaments are still prizes for archaeologists and the subject of a long controversy as to their origin and design. A settlement was planned and a small group of Spaniards headed by Bartolomé Columbus, brother of Christopher, was landed. The group remained only a short time, however, and after attack by the Indians and the loss of a number of men, set sail and joined Columbus farther down the coast. The name of the country, Costa Rica, or "rich coast," was possibly the result of Columbus' discovery of gold. Another explanation, suggested by the U.S. geographer George E. Church, is that the name is a corruption of *costa de oreja* ("earring coast").

Costa Rica was at first called Nueva Cartago before it became a province of the captaincy general of Guatemala, but by 1540 the name Costa Rica had been generally adopted. The Spaniards pacified the region by 1530 and made it a province in 1540. Its limits were surveyed and fixed between 1560 and 1573 under Juan Vázquez de Coronado, one of the few able and conscientious Spanish governors in the long history of the province. Costa Rica was one of the most backward of Spanish possessions in America and, though nominally under the captaincy general of Guatemala, paid little attention to that authority. Its citizens were largely poor farmers whose only income came from the illegal sale of tobacco to Panama or to British smugglers. Costa Ricans viewed

Guatemala as the source of their poverty because taxes were levied from that city and officials were sent from there to enforce the Spanish mercantilist laws.

**2. Independence.**—Along with the rest of Central America, Costa Rica became independent on Sept. 15, 1821, when word was received that Mexico had successfully revolted against Spain. Although its poverty and lack of population caused Costa Rica briefly to join Mexico and, in 1824, to join the Central American Federation (*q.v.*), many citizens favoured a policy of complete separation from isthmian politics. The "Ticos," as they call themselves, felt unique among Central Americans. Because the Indian population of the country was slight there were few mestizos, and a very large percentage of the people were pure white. There was little mineral wealth and no landed aristocracy. While the general cultural and economic level during the early 19th century was low there were no sharp class distinctions. Few Costa Ricans could be considered wealthy, and there was no vast labour supply awaiting exploitation as in the Indian lands of Spanish America. These differences from the rest of Central America, coupled with distrust of Guatemalan power and size stemming from colonial times, brought about a policy of isolationism. With the dissolution of the Central American Federation the last official ties were soon broken, and in 1838 Costa Rica went its own way. Attempts among the five nations to revive the federation have met least response in Costa Rica.

Poor communication and the natural distrust of peasants brought about serious provincial rivalry that bore the meaningless terms of "Liberal" and "Conservative" but also reflected a desire to possess the capital city. In colonial times the capital city was Cartago; a brief civil war in 1823 brought the capital to San José. Rivalry between Cartago, San José and other towns led to the absurd "Ley de Ambulancia" of 1834 which provided that the government of Costa Rica be rotated every four years among the four largest towns. Much of this competition declined in later years as San José grew much more rapidly than the others.

Foreign demand for coffee brought the steady income that Costa Rica needed. Beginning in the 1840s a constant train of picturesque oxcarts carried coffee from the Meseta Central to Pacific ports and European-bound ships. British investment in Costa Rica was large. Small farmers could derive a simple, comfortable existence, and the groundwork was laid for a rural society that demanded schools and roads from its government

and found political participation necessary to achieve these goals.

Costa Rica shared the San Juan river with Nicaragua and suffered from some of the canal fever and filibustering that nearly destroyed her northern neighbour. The two nations were often on bad terms because of disputes over boundaries (settled by treaty in 1896), and because the large province of Guanacaste seceded from Nicaragua and joined Costa Rica in 1825. British interest in Costa Rica and North American activity agitated this rivalry in the mid-19th century. However, when William Walker (*q.v.*) invaded Nicaragua in 1855 Costa Rica came to its assistance and under the leadership of Pres. Juan Rafael Mora defeated Walker at Rivas in Nicaragua.

**3. Material Progress.**—Costa Rica was not without some of the political partisanship found elsewhere in Central America, but it was less prolonged and less bitter. Material progress came about rapidly in the administration of Gen. Tomás Guardia who dominated Costa Rica by dictatorial methods from 1870 to 1882. While liberty was curtailed and heavy debts assumed, commerce in sugar and coffee increased substantially and a large program of school construction began. A new constitution was adopted in 1871 and continued in effect until 1949. The railroad building program during the 1870s and 1880s ended Costa Rica's isolation from the world. With funds borrowed mainly from Great Britain, Costa Rica began to link the Meseta Central with the seaports. The chief promoter was Minor C. Keith who made a fortune with the opening of the rail line between Cartago and Limón. Keith entered the banana business, as did about 20 other companies, on the basis of vast land grants from Costa Rica for building the railway. From this period on bananas regularly rivaled coffee as the chief source of income for Costa Rica. In 1899 the United Fruit company took over Keith's investments.

The last decades of the 19th century were marked by a gradual relaxation of Roman Catholic Church activity in secular affairs. The Jesuits were expelled for a few years; cemeteries were secularized; and public education was expanded. The constitution of 1871 provided religious toleration although the government continued to support the Roman Catholic Church. A law of 1886 provided free and compulsory public education. A normal school, a museum and a national library were founded.

In spite of great bitterness, a truly democratic election in 1890 resulted in victory for José Joaquín Rodríguez—an election sometimes considered the first entirely free and honest election in

vention caused Tinoco to resign, and he went into exile in 1919. Julio Acosta was then elected president and was promptly recognized by the United States. Under Acosta and succeeding presidents Costa Rica acquired the reputation of being the most democratic and orderly republic in the Americas. It continued its tradition of democratic elections and nonmilitary rulers. President Acosta was followed in orderly succession by Ricardo Jiménez Oreamuno (1924–28), who had served one previous term, Cleto González Víquez (1928–32), Jiménez for a third term (1932–36), León Cortés (1936–40), Rafael Angel Calderón Guardia (1940–44) and Teodoro Picado Michalski (1944–48). A literacy test for voters was adopted in 1920 and the secret ballot in 1925. The country participated for a few years in the activities of the League of Nations but withdrew in 1924. On Dec. 8, 1941, the day after Japan attacked Pearl

Harbor, the Costa Rican congress declared war on Japan even before the United States did, and on Dec. 11, 1941, declared war on Germany and Italy.

The only serious political crisis since 1917 came in 1948. A faction containing some alleged Communists tried to prevent the seating of the president-elect, Otilio Ulate. A socialist landowner named José Figueres put down the rebellion and turned the government over to Ulate. A new constitution was adopted in 1949. Figueres soon turned against Ulate and was legally elected president himself in 1953. Figueres nationalized the banks and threatened the United Fruit company and power company holdings. Aided by the Organization of American States, Costa Rica in 1955 repelled an invasion mounted by exiles in Nicaragua. In 1958 Mario Echandi Jiménez was elected president to succeed Figueres. Echandi was succeeded in 1962 by Figueres-backed Francisco J. Orlich. Orlich supported Daniel Oduber in the 1966 election, but Oduber was defeated by José Trejos Fernández.

After 1950 Costa Rica changed dramatically. It still relied heavily on agricultural exports for income but assumed many aspects of an industrialized society. The number of commercial and industrial establishments increased greatly.

In March 1963 the presidents of Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua and Panama met with U.S. Pres. John F. Kennedy in San José. Kennedy emphasized contributions in financial aid under the Alliance for Progress to bolster the region's economy.

In March 1963 Mt. Irazú erupted and poured sulfurous ash over much of the Central Plateau. Crops and animals were poisoned, and many persons in Cartage and San José were made ill. The volcanic ashfall continued into 1964 and brought serious dislocation to Costa Rica's economy. By the mid-1960s the eruptions had ceased, and the economy began to recover. (T. L. K.)

## V. POPULATION

Costa Rica's population was estimated at 1,485,506 in 1966, an increase of more than 500,000 over the number reported in the census of 1950, and well over twice the population in 1927, when the last previous census was taken. Costa Rica's population is growing at one of the highest rates in the world. The birth rate per 1,000 was about 47 in the mid-1960s, even higher than the previous rates of 45 in 1938 and 46.5 in 1950. The death rate of Costa Rica meanwhile dropped and infant mortality fell rapidly. The average density is almost 70 per square mile. The ma-

Central America. It helped dramatize and strengthen the tradition of democracy for which Costa Rica is famed among Latin-American nations.

**4. 20th Century.**—In 1916 the United States and Nicaragua concluded the Bryan-Chamorro treaty by which Nicaragua gave the United States permission to use the San Juan river as a portion of an interoceanic canal route. Costa Rica protested that its rights in the San Juan river were being ignored. The claim, based on a treaty of 1858 and reaffirmed in an award of Pres. Grover Cleveland, was brought before the Central American court of justice. The court ruled that Nicaragua had violated Costa Rican rights, but both Nicaragua and the United States refused to accept the decision. This case was a significant factor in the destruction of the court. (See also FONSECA, GULF OF.)

The boundary with Panama (originally with Colombia) was not delimited until 1941. An arbitration award by the president of France in 1900, confirmed by the chief justice of the United States in 1914, was generally favourable to Costa Rica, but was rejected by Panama, which continued to hold part of the disputed area. Finally, in 1921, Costa Rica attempted forcible occupation of the Coto region (on the Pacific coast), which had been adjudicated to it. Large-scale hostilities were averted only by the intervention of the United States in support of Costa Rica's claim. Panama thereupon evacuated the Coto area, but relations between the two countries were broken until 1928, and the dispute continued. A treaty of settlement was made in 1938, but opposition in Costa Rica was so strong that it was withdrawn from congressional consideration unratified. Finally, in 1941 the government of Rafael Calderón Guardia reached an agreement with Panama delimiting the common boundary.

When Costa Rica held an election under a system of direct suffrage for the first time in 1913 no candidate won a majority and the congress then chose Alfredo González as president. One of his supporters, Gen. Federico Tinoco, became disgruntled with the tax revision and other reforms proposed by the González government and staged a successful revolution in Jan. 1917. Tinoco failed to take advantage of his popularity and behaved despotically at times. His administration was hindered by the refusal of the U.S. government to recognize regimes brought into office by force. During Tinoco's dictatorship Costa Rica declared war on Germany, but the president of the United States, Woodrow Wilson, succeeded in keeping Costa Ricans from participating in the treaty of Versailles discussions. Numerous revolts and the danger of inter-

San José . . . .	2,008	487,658	San José . . . .	101,162

VI. ADMINISTRATION AND SOCIAL CONDITIONS

1. Government.—The constitution of 1949, the eighth since 1825, provides for a unitary state with separation of powers (legislative, executive and judicial branches) but with some characteristics of the parliamentary system. The constitution of 1871 provided that the president's ministers could attend legislative sessions but could not vote. The constitution of 1949 empowers the legislature to force the ministers to appear before it and be subjected to question and to censure. Despite this, the legislative assembly is subordinate in practice to a centralized political and governmental system headed by a powerful executive elected directly for a four-year term. The legislature consists of only one chamber; its members, known as deputies, are elected for four-year terms.

The constitution provides for two presidential designates. If no presidential candidate receives at least 40% of the popular vote a runoff election among the major candidates must be held. Three per cent of the national budget is devoted in election years toward defraying the campaign expenditures of all parties that receive at least 10% of the total vote. Both men and women (since 1949) are permitted to vote, and voting is compulsory for all eligible male citizens under 70 years of age.

The governors of the seven provinces are appointed by the president, and the subdivisions of the provinces—cantons and districts—are strongly influenced by centralized controls.

The judicial branch is centralized. The legislative assembly

elects the supreme court, which in turn appoints the justices of the appellate courts and courts of original jurisdiction. An act of 1937 provided for a type of judicial review under which the supreme court can declare that a law or executive decree is inapplicable to a particular act. This power has not been used as a check on either the powerful executive or the legislature.

2. Education.—The education budget is usually at least 20% of the total budget and is the highest of all the ministries. According to the 1950 census 79.1% of the population 10 years of age or older was literate. There are several technical institutes and universities. The average length of primary school enrollment is only four to five years and those who have learned to read are frequently unable to practise their skill because of the lack of books, magazines and newspapers, especially in the rural areas. Elementary education is free and compulsory for children between the ages of 7

and 14 years but many do not attend school. Education follows the European model of the centralized ministry, which controls policy and administration for all of the schools in the entire country.

3. Labour and Social Welfare.—The social insurance system is based on the laws of 1941 and 1943 as amended. Employers employees and the government contribute to a system which provides cash benefits and medical, maternity and dependents care. The system is administered by the department of labour and social welfare. In addition, there is a workmen's compensation program which was established in 1924, and a system of old-age insurance.

The labour code of 1943 guarantees the right to organize, to bargain collectively and to strike. The government provides labour courts and procedures for arbitration and conciliation. The labour unions were infiltrated and at times controlled by Communists after World War II. (W. S. S.)

## VII. THE ECONOMY

As noted above, the economy of Costa Rica rests principally upon production and processing of agricultural commodities but manufacturing and transportation made significant gains after 1950.

**1. Production.**—According to the 1960 census, agricultural land comprised 2,478,500 ac., or almost 20% of the country's total area. Of the agricultural land about 64% was in permanent pasture; 14% in permanent crops (coffee, sugar, bananas, cacao, abacá, pineapples, etc.); 11% in annual crops (corn, beans, rice, vegetables, tobacco, etc.); while about 8% of annual cropland lay fallow. Agricultural production is sufficient to meet most domestic needs of these products and also to provide substantial quantities of coffee, bananas, cacao, abacá and cattle for export. Forests, occupying 80% of the country's area, supply the bulk of domestic needs for forest products and also exports including cedar, cativo (soft wood used in plywood), cabinet woods and balsa.

Known mineral resources are generally meagre, but clays, cement materials, gold, salt and sulfur are produced. An important deposit of sulfur was discovered near San Carlos in 1966. Fisheries employ about 200 men and 150 boats and the annual catch totals about 450,000 lb. There is a combined storage and freezing plant at Puntarenas. Tuna, turtles and shark livers are exported. As Costa Rica produces no fuel other than wood, it depends heavily upon electric power generated from water power in the highlands. The electrical industry was nationalized in 1928. Industrial plants are small and produce chiefly consumer goods.

**2. Trade and Finance.**—Costa Rica's chief exports are coffee, bananas, cacao, cattle, abacá, fertilizers, forest products. Principal imports are machinery, transportation equipment, chemical products, textiles, foodstuffs, minerals, forest products, fuels, and iron and steel. Leading customers are the United States, West Germany, Canada and the Netherlands; chief suppliers are the United States, West Germany, the United Kingdom and Japan. In 1960 Costa Rica joined its neighbours in a proposed Central American common market to promote trade.

The monetary unit is the colón, valued in the mid-1960s at about 15 cents, U.S. currency, official rate. The Banco Central de Costa Rica directs monetary policy, foreign exchange and facilities for credit and supervises the banking system. There are four government-owned commercial banks and one foreign-owned bank. The latter cannot accept private deposits. The main source of government revenue is the income tax paid by the United Fruit company.

**3. Transportation and Communications.**—In 1957 the U.S. Export-Import bank lent \$9,540,000 to finance Costa Rica's share of the unfinished sections of the Inter-American highway. Railways include more than 250 mi. of public service lines and several hundred miles of private plantation lines. In 1961 the World bank and the International Development association announced a loan of \$11,000,000 was being granted to Costa Rica for highway construction.

Passenger air movement in and out of Costa Rica is largely via Pan American World Airways, Royal Dutch Airlines (KLM), TACA International Airlines and the Costa Rican national airline, LACSA. Their subsidiary lines link San José by daily passenger and airmail services with all important towns. El Coco, the capital's airfield, opened in June 1955, can handle the most modern aircraft.

The government operates domestic telegraph and radio stations and part of the telephone system. There are also international radiotelegraph circuits to Nicaragua, Honduras, El Salvador and Mexico. Except for several hundred government telephones the telephone system is privately owned. Regular telephone services operate between San José and the six other provincial capitals. Television was inaugurated in 1960. See also references under "Costa Rica" in the Index.

Furbay, *Education in Costa Rica* (1946); Stacy May et al., *Costa Rica: a Study in Economic Development* (1952); Watt Stewart, *Keith and Costa Rica* (1964). (C. F. J.)

**COSTA Y MARTÍNEZ, JOAQUÍN** (1846–1911), Spanish jurist and historian who was also a political thinker deeply concerned with the decline of Spain in the industrial age. Born at Monzón, Huesca, Sept. 14, 1846, he was the eldest of a farmer's 11 children. He studied law, philosophy and letters at Madrid university, where, from 1874, he held a minor teaching post. After 1884 he worked at the ministry of ecclesiastical affairs and justice. The loss of Cuba in 1898 wounded his patriotism and he began to preach a regeneration of Spain. Although his sympathies were with regionalism and colonialism, he also favoured the "Europeanization" of the country. The paradox of his position was expressed by his *Reconstitución y europeización* (1900), where reconstitution meant a return to ancient values and Europeanization meant going forward with the rest of Europe. An advocate of revolution, he refused to accept his seat when elected to the *Cortes* in 1903, holding that republicanism would not be viable until established by force. He wrote on Hispano-Celtic literature and myth (*La poesía popular española, y Mitología y Literatura celtio-hispanas*, 1881), legal theory (*Teoría del hecho jurídico, individual y social*, 1880), agrarian reform (*El colectivismo agrario*, 1898) and politics (*Oligarquía y caciquismo*, 1901–02). His last years were spent in combating the law against terrorism introduced by Antonio Maura in 1908 and in writing *Ultimo día del paganismo* (1909).

He died at Graus, Huesca, Feb. 8, 1911.

(Ay. K.)

**COSTER, CHARLES THÉODORE HENRI DE** (1827–1879), Belgian author, outstanding among those of his countrymen who wrote in French during the 19th century, was born of Belgian parents in Munich, Bavaria, Aug. 20, 1827. His tastes were always those of a millionaire, his means only those of a rag-picker; and he earned a living finally as a teacher of French at the École Militaire in Brussels, where he died (May 17, 1879) before fame had come to reward his literary achievement.

His writings include *Légendes flamandes* (1857), *Contes brabançons* (1861) and a remarkable travel book, *La Zélande* (1873). His masterpiece is *La Légende et les aventures héroïques, joyeuses et glorieuses d'Ulenspiegel et de Lamme Goedzak au pays de Flandres et ailleurs*, which it took him ten years to write. Published in 1867, it was many times reprinted and translated into a number of foreign languages (Eng. trans. 1943).

The story of *Ulenspiegel* takes place in the 16th century, at the height of the Inquisition's reign of terror: the hero's father is burned at the stake as a heretic, and Ulenspiegel swears an oath to avenge him. De Coster presents his characters as combining heroic qualities with a typically Belgian realism. The style is highly coloured and richly archaic, being derived from Rabelais, from Montaigne and from the 16th-century chroniclers. With its theme of resistance against oppression, the book has been called "the Bible of Flanders" and "the breviary of freedom"; yet neither the gruesome death scenes and the shrieks of the tortured, nor, on the other hand, a certain tendency to philosophize, prevent its being, as the author describes it, "a merry, jovial book, a work of art and of literature." The contrast between it and the commonplace novels of the period is sharp and striking.

See Joseph Hanse, *Charles De Coster et son oeuvre* (1928).

**COSTIGAN, EDWARD PRENTISS** (1874–1939), U.S. lawyer, member of the U.S. Tariff commission and senator from Colorado, was born in King William county, Va., on July 1, 1874. He spent most of his youth in Colorado, where his parents moved in 1877. He graduated from Harvard in 1899 and began his law practice in Denver the next year. His interest in good government led him to join nonpartisan organizations designed to improve municipal and state government in Colorado, including the Direct Primary league, which he helped organize. A Republican and a supporter of Theodore Roosevelt, he bolted the party to help organize the Progressive party of Colorado in 1912 and to become its unsuccessful candidate for governor in that year and again in 1914. As an attorney he represented the Denver chamber of commerce and the United Mine Workers of America in federal litigation. In 1916 he became a supporter of Pres. Woodrow Wilson, who later appointed him to the newly created Tariff

commission. He served with distinction on the commission as an advocate of a flexible tariff until he resigned in 1928 in protest against the high-tariff policies of the Coolidge administration. He re-entered Colorado politics as a Democrat and was elected U.S. senator in 1930. He proposed far-reaching legislation to meet problems created by the depression and worked effectively for New Deal measures of Pres. Franklin D. Roosevelt. He was cosponsor of the Jones-Costigan act, a sugar-quota measure, as well as of the Costigan-Wagner bill, an antilynching proposal that never became law. Ill from overwork, he gave up his senate duties in 1936. He died in Denver, Jan. 17, 1939.

(C. F. McL.)

**COST OF LIVING.** The term cost of living is often employed in ordinary conversation without a clear conception of its true meaning. Since official measurements of the cost of living have been used for purposes for which they were not intended, the use of this particular term was replaced in the United States in 1945 by "consumer price index" and in Great Britain in 1947 by "index of retail prices."

All measurements of the cost of living or of the level of retail prices are concerned with the calculation of the cost at current prices of purchasing, in a particular place or area, of a certain collection of consumers' goods and services. This collection of goods and services may be what some recognized authority considers to be the minimum necessary to preserve health and strength or, more commonly, may consist of those goods and services on which it has been found by an empirical investigation a particular class of people in a given area habitually spend or have spent their income. The purpose of this survey is to describe in general terms the uses for which such measurements are required and the methods by which they are made. Further discussion of the variation in methods used in different countries will follow, together with a statistical table showing the comparative movements in the cost of living or level of retail prices before World War II and from 1952 to 1959 in selected countries. The evidence should make it clear that any measurement of the cost of living or of the level of retail prices is at best a rough approximation. See also PRICES, STATISTICS OF.

### GENERAL CONSIDERATIONS

**Purposes for Which Measurement Is Required.**—The earlier uses of the measurement of the cost of living were chiefly concerned with the incidence of poverty, and this involved absolute measurement rather than the comparative measurement which later became more usual. The goods and services which a family of given size required to maintain health and efficiency for work were specified and the cost of this list of commodities at prices then current was calculated. This figure then disclosed the minimum income required by the family to furnish it with the essentials of life provided that due economy was practised. Any family whose income fell below this minimum level could be said to be living in poverty ascribable to an insufficiency of income rather than to other causes. Such in broad outline were the uses to which the cost of living was put by pioneers such as Benjamin Seebohm Rowntree (in *Poverty*, 1922, and in *Poverty and Progress*, 1941) and Arthur Bowley (in *Livelihood and Poverty*, 1915, and in *Has Poverty Diminished?* 1925). Unfortunately the concept of a minimum standard is an ambiguous one. As far as food is concerned, requirements cannot be assessed purely in terms of calorific value, and for items of expenditure such as housing, furniture, etc., the list must be determined by custom rather than by strict necessity. Even if the minimum calorific needs and minimum requirements of carbohydrates and protein could be made to serve as the basis of a diet, such requirements would vary according to the kind of work that had to be performed. In spite of these objections, the use made of the ideas set forth here was fully justified by the attention which it focused on a great social evil.

The second use for which cost-of-living measurements are required concerns the comparison over a period of time of the effect of changes in retail prices on a collection of goods and services which it was customary for a specified class of people to buy in a

certain (base) year. Thus, in Great Britain until 1947 calculations were made of the changes since 1914 in the cost of a collection of goods customarily purchased by working-class families in 1904. Calculations on this basis take no account of the fact that, as time passes, the collection of goods which is priced is not typical of the expenditure of the class of people on which it was originally based. Four reasons for this change in the pattern of the expenditure may be distinguished:

1. As the prices of different commodities change, there is a tendency to substitute goods that become cheaper for those that become more expensive.
2. New commodities come onto the market and obsolete goods cease to be produced or are produced in decreasing quantities.
3. Social factors cause a progressive change of tastes.
4. If the economic class of people to which the calculation refers is defined in terms such as manual workers, professional workers or farm workers, the whole class may, over the course of time, find that their incomes enable them to purchase an increased quantity of all goods.

These possibilities draw attention to the option that exists in measuring the cost of living. We may wish to measure the changes caused by alterations in retail prices in the cost of maintaining a fixed level of "economic welfare" or "satisfaction"; and in this case it is necessary, ideally, to take account of changes in the pattern of expenditure caused by (1), (2) and (3) above. Alternatively, interest may centre on the changes in the cost of the collection of goods currently purchased by a given economic class of people irrespective of the fact that some while ago they were restricted by virtue of their income to a somewhat smaller collection. If this is the case we must take account of all four of the causes operating to change the pattern of expenditure. This then is a third use for cost-of-living measurement.

Unfortunately there is no practical means of measuring the cost of goods and services affording a constant level of economic satisfaction, since to find the pattern of expenditure corresponding to such a level requires a knowledge of the money income necessary to afford the required satisfaction and this could not be calculated without prior knowledge of the level of retail prices, which is the unknown that is being sought. There is thus no general alternative to the method of pricing a fixed collection of goods from year to year and assuming away the effects of relative price changes, new commodities and changes in tastes.

No such obstacles prevent the practical measurement of the cost of goods currently purchased by a given group of people, provided that such a group can be objectively defined in terms of the occupation to which they belong or the areas in which they live. Any definition depending on income, however, would be open to serious objection, for definition by real income would again beg the question to be answered, and definition by money income would provide a group of which the level of economic welfare was falling in times of rising prices (and vice versa), irrespective of the course of money incomes in the area concerned.

In 1947 the sixth International Conference of Labour Statisticians recommended (in *Cost of Living Statistics*, International Labour office, Geneva, 1948) that in the period after World War II cost-of-living indexes should be used for measuring the changes in the cost of a pattern of expenditure typical of a given economic group before the war and for measuring the changes in the cost of the current pattern of expenditure typical of a given economic group. These uses correspond to the second and third uses described above. In addition, the conference recommended another use which is an adaptation of the first use given earlier: i.e., that changes in the cost of a collection of goods corresponding to a given standard of adequacy should be calculated taking account so far as was possible of the changes in the collection of goods induced by relative price changes. Such allowances can be made in the case of food and clothing by relating the new collection to the old by ensuring that the same calorific value and the same vitamins, minerals, etc., are provided, in the case of food and that the same general specification and purpose are satisfied for clothing.

A fourth use for cost-of-living calculations has been the com-

parison of the cost of living for members of the same economic group living in two different places or areas during the same period. Clearly the same collection of goods must be priced in the two places, but is it to be the collection appropriate to the one place or to the other or some average of the two collections? Any of these methods is equally valid, but each will not produce the same answer and in some cases the results may contradict one another.

During World War II measurements of the cost of living had secondary uses as indicators of the effectiveness of price controls. Further, in Great Britain, for instance, subsidies were paid to farmers and others to prevent the retail price of certain commodities from rising. Insofar as the cost-of-living index was calculated on the basis of an obsolete pattern of consumption, its limited movement tended to exaggerate the effectiveness of such subsidies.

The composition of the collection of goods to be priced at two different times may present difficulties. Goods for which one once had to pay may come to be supplied free by a beneficent state. Almost certainly such a development would be accompanied by increased direct taxation and in principle the goods concerned should be priced according to the incidence of taxation for this particular purpose on the group of people for whom the index is calculated. There was little evidence at mid-20th century that this problem had yet been faced, but clearly if the welfare state developed further it would be a most important one.

**Methods of Measurement.**—The first requirement is to make a family budget study of the economic class of people for whom the index of retail prices is to be calculated. The economic group must be carefully defined in an objective way and a sample of families must be obtained so that all the members of the group are adequately represented. This means that every family in an economic class must have either an equal or a known chance of being selected for the sample; i.e., the sample of families must be chosen at random from the economic class concerned.

The families in the selected sample must then be asked to record particulars of their expenditure in certain stated periods. The periods may vary in length according to the type of expenditure concerned; thus, in Great Britain in the ministry of labour's household budget inquiry of 1937-38, nearly 9,000 households were asked to supply budgets for each of four separate weeks in Oct. 1937 and January, April and July 1938. About one-quarter of these households were also asked to supply weekly returns of their expenditure on clothing over the 12 months from Oct. 1937. In this case the economic class concerned consisted of manual wage earners generally and nonmanual workers with salaries not exceeding £250 a year. The inquiry held between Jan. 1953 and Jan. 1954 excluded households for which the gross income of the head of the family was £20 a week or over in 1953, or which were mainly dependent on national insurance pensions or public assistance. It was based on budgets supplied by 11,638 households between these limits, a sample which represented nearly nine-tenths of the households in the U.K. and where, on the average, in every 100 households, 149 persons worked for gain, 12 were retired and 94 were children.

The material so obtained must then be collated and certain items of expenditure are in practice discarded. In most countries expenditure on direct taxes is excluded but this is not the case in some, such as Sweden and South Africa. Other items often left out are insurance contributions and premiums, subscriptions to trade unions, church collections, gifts in cash and expenditure on betting. The remaining items of expenditure are grouped together in sections that contain commodities that are likely to have broadly similar price movements. The sections are then combined into groups of the same general character such as food, rent, clothing, fuel and light, household goods, etc. The proportion of total expenditure of the class of people concerned on the items included in the sections and groups can then be calculated. Where there is evidence that expenditure on certain commodities has been understated, adjustments must be made to correct this inaccuracy. Expenditure on alcoholic drinks and tobacco is likely to be underrepresented if the results of the budget study are accepted uncritically.

From each section, commodities must be chosen for which

there is good price information and which are likely to show price movements typical of all the items in the class. Commodities fulfilling these requirements must be specified as accurately as possible and arrangements must be made to obtain their prices at the appropriate intervals, usually of one month. Special difficulties arise in the case of commodities with seasonal variations in supply, such as fresh fruit and vegetables; before World War II these goods were often omitted altogether. Various devices were adopted to overcome this problem in different countries and one example will be mentioned here. In Sweden, beginning in 1941, the price during the month when a new crop came on the market was taken as the current price. In the following month the price used was the average of this month's price and that of the preceding month; in the third month an average of three months' prices was taken and so on until the sixth month, when the price used was the average of the six months following the arrival of the new crop. The price used in the sixth month was unaltered for the following months until the next new crop was produced. This procedure was justified on the grounds that the housewife has the option of buying supplies as necessary or of buying several months' supply at once and preserving the fruits and vegetables for later use.

If a new type of commodity is introduced and the old type of article is no longer available, some effort must be made to take into account the change in quality. A possible solution is to ask retailers to estimate what price should be quoted for the new article in order to make it sell as freely as the old.

When price controls and rationing are in force and if there is a substantial "black market" in any commodity, the existence of this state of affairs must be reflected in the prices of the commodity concerned provided that black-market prices can be collected with sufficient accuracy.

In order to illustrate the numerical calculation of a retail price index, use will be made of an artificial and simple example. Suppose that a group of people, appropriately defined, purchase four commodities only; namely, bread, coal, cloth and housing. Family budget studies taken in three successive years I, II and III disclose that the following proportions of total family expenditure are devoted to the four commodities in the three years:

	Year I %	Year II %	Year III %
Bread . . . . .	60	50	40
Coal . . . . .	8	10	12
Cloth . . . . .	14	19	23
Housing . . . . .	18	21	25

The price information obtained shows that in years II and III the prices of the four commodities expressed as a percentage of the prices in year I are as follows:

	Year II %	Year III %
Bread . . . . .	110	120
Coal . . . . .	120	140
Cloth . . . . .	125	150
Housing . . . . .	115	125

Then the cost of the pattern of the expenditure of year I in year II as a percentage of the cost of the same pattern in year I is

$$\frac{60 \times 110 + 8 \times 120 + 14 \times 125 + 18 \times 115}{60 \times 100 + 8 \times 100 + 14 \times 100 + 18 \times 100} \times 100 = 113.8$$

Similarly the cost of the same pattern in year III as a percentage of its cost in year I is

$$\frac{60 \times 120 + 8 \times 140 + 14 \times 150 + 18 \times 125}{60 \times 100 + 8 \times 100 + 14 \times 100 + 18 \times 100} \times 100 = 126.7$$

Thus the retail price index as measured by the changes in the cost of the collection of goods bought in year I is 113.8 in year II and 126.7 in year III compared with the cost in base year I of 100.

If it is desired to take into account the changed pattern of the expenditure of the economic class of families concerned, the index could be obtained for year II as before, but for year III

the cost of the pattern of expenditure of year II in year III as a percentage of the cost in year II can be calculated. This proportion is

$$\frac{50 \times 120 + 10 \times 140 + 19 \times 150 + 21 \times 125}{50 \times 110 + 10 \times 120 + 19 \times 125 + 21 \times 115} \times 100 = 112.1$$

The level of prices in years I and III can be compared by the "chain method"; i.e., the retail price index is 100 in year I,

$$113.8 \text{ in year II and } 113.8 \times \frac{112.1}{100} = 127.6 \text{ in year III.}$$

If further the cost of the pattern of year III in year IV as a percentage of its cost in year IV was, say, 98.0, the retail price index in year IV on year I as base would be

$$127.6 \times \frac{98.0}{100} = 125.0$$

It is worthwhile noticing that if the cost of the pattern of year III in years I and III were compared the retail price index would be 130.1 and not 126.7. This difference is caused by the fact that the families have switched their expenditure from bread, of which the price has risen less than average, to cloth and coal, of which the price has risen more than average.

The calculation of the index number used in this illustration can be described by means of an algebraic formula. If the quantities of various goods purchased in year I are denoted by  $q_1, q_2, q_3, \dots$ , etc., and the prices by  $p_1, p_2, p_3, \dots$ , etc., and if the prices of the same goods in year II are denoted by  $p'_1, p'_2, p'_3, \dots$ , etc., then the retail price index in year II on year I as base is

$$\frac{p'_1 q_1 + p'_2 q_2 + p'_3 q_3 + \dots}{p_1 q_1 + p_2 q_2 + p_3 q_3 + \dots} \times 100$$

This form of index number is that derived from Etienne Laspeyres. The formula may be rewritten in a different way as

$$\frac{\left(\frac{100 p'_1}{p_1}\right) p_1 q_1 + \left(\frac{100 p'_2}{p_2}\right) p_2 q_2 + \dots}{p_1 q_1 + p_2 q_2 + \dots}$$

It is then seen to be the "weighted" average of the "price relatives"  $\frac{100 p'_1}{p_1}, \frac{100 p'_2}{p_2}, \dots$  (i.e., the prices in year II as percentages of the prices in year I) with  $p_1 q_1, p_2 q_2, \dots$  (i.e., the expenditure in year I) as the weights.

#### UNITED STATES

Three types of measures of cost of living are reviewed here: (1) changes in cost of living; (2) how much it costs to live; (3) differences in cost of living from place to place. Interest in the first of these measures tends to be high in periods of rising prices which bring demands for wage increases to maintain customary levels of consumption. When prices are stationary or falling, those seeking higher wages tend to stress the dollar cost of a minimum or decent level of consumption, especially for those in low-paid occupations. Differences in cost of living from place to place are considered in wage negotiation and other issues bearing on income distribution. Facts as to price changes are also important in making decisions as to monetary and fiscal policy.

**Changes in Cost of Living.**—The consumer price index (C.P.I.) of the U.S. bureau of labour statistics (BLS) is the most important measure of changes in the cost of living in the United States. Its retail food index ( $R_f$ ) goes back to 1890 and that of all consumption categories to 1913. The index is designed to measure changes in the prices paid for a selected budget of a base year. It is based on the index formula of Etienne Laspeyres (see *General Considerations*, above):

$$R_f = \frac{\sum q_0 p_i}{\sum q_0 p_0}$$

where the  $q_0$ 's are the average quantities used in the base year of each of the items priced, the  $p_0$ 's are their prices in the base year and the  $p_i$ 's are current prices. This type of index tends to indicate a greater price increase than one using the Paasche for-

mula in which the quantity weights represent consumption in the current rather than the base year.

The consumer price index measures average changes in prices of goods and services bought by city families of wage earners and clerical workers. It is based on prices of about 300 items so selected that their prices represent the movement of prices of all goods and services purchased by the families of wage earners and clerical workers. All important items in families' spending are represented with the exception of life insurance and income taxes. The inclusion of an item is determined by its importance and its price movement. Because the ability of one item to represent the price change of other items is not widely understood, the C.P.I. includes important items even though the index would be essentially the same if they were represented by other items also priced. The pricing of a large number of items contributes to the credibility of the index as an accurate measure of price change.

TABLE I.—Annual Average Index of Consumer Price Index in the United States, Selected Years 1915 to 1960 (1947-49=100)

Year	All items	Food	Clothing	Housing total	Rent	Transportation	Medical care	Other goods and services
1915	43.4	40.0	47.3	—	77.2	—	—	—
1920	85.7	83.6	105.1	—	100.2	—	—	—
1930	71.4	62.4	58.9	—	114.2	—	—	—
1940	59.9	47.8	51.2	—	86.9	—	—	—
1950	102.8	101.2	98.1	106.1	108.8	111.3	106.0	105.2
1951	111.0	112.6	106.9	112.4	113.1	118.4	111.1	109.7
1952	113.5	114.6	105.8	114.6	117.9	126.2	117.2	115.4
1953	114.4	112.8	104.8	117.7	124.1	129.7	121.3	118.2
1954	114.8	112.6	104.3	119.1	128.5	128.0	125.2	120.1
1955	114.5	110.9	103.7	120.0	140.3	126.4	128.0	120.2
1956	116.2	111.7	105.5	121.7	142.7	128.7	132.6	115.9
1957	120.2	115.4	106.9	125.6	145.2	136.0	138.0	119.8
1958	121.5	120.3	107.0	127.7	147.7	140.5	144.6	123.0
1959	124.6	118.3	107.9	129.2	149.7	146.3	150.8	125.3
1960	126.5	119.7	109.4	131.5	141.8	146.2	156.2	127.9

Prices are obtained in 46 cities chosen to represent all urban places in the United States, and are collected from grocery, drug and department stores, hospitals, filling stations and other places patronized by families of wage earners and clerical workers. Prices of foods, fuels and a few other items are obtained every month in all 46 cities. Prices of most other commodities and services are collected every month in the five largest cities and every three months in other cities. Almost all prices are obtained by personal visits. In calculating the index, price changes are averaged together with weights representing their importance. City data are then combined in the total index with weights based on the 1950 population of cities represented.

The items priced and their quality and weights are determined by data secured from urban families. The initial food index used data collected for the year 1901 from workingmen's families in 33 cities. The first full-scale cost-of-living index used weights based on a survey of families of wage earners and low-salaried clerical workers in 92 cities for the years 1918-19. The next major revision of the weights used data obtained from families of similar workers in 42 cities during 1934-36. Automobiles and electric refrigerators were introduced into the index at that time. During the late 1940s family surveys in a few large cities indicated that some change in commodity weights was needed, and an interim revision of the index was made in 1951 pending the comprehensive revision of 1953. Several items were added because of their increased importance, e.g., frozen peas, concentrated orange juice and television sets; other items were added because of a change in relative price movements. Probably the most important change was the reduction in the importance attached to food. Because of greater increase in the price of food than of other consumer goods the importance of food in the index increased from 35% in 1935 to 40% in 1950. Yet studies showed that about 35% of family outlays in 1950, as in 1935, went for food. A large-scale survey of urban families covering the year 1950 provided data for a comprehensive revision of commodities and their weights. Among the important changes were the inclusion for the first time of restaurant meals, used cars, items for the maintenance of owner-occupied dwellings and the purchase price of dwellings. These were all items of increased importance and their price movements appeared to have certain unique features.

A general revision of the index calls for an extensive survey of

family consumption. Between such surveys some substitutions are likely to be made. Long before the 1934-36 survey, women's high-buttoned shoes, in general use in 1918-19, had disappeared from shops. They were replaced in the index by the type of shoes that replaced them in use. When such changes are made the price of the new goods is introduced with a link so that its price change only and not the price difference between the "old" and the "new" goods affect the index. This method is also used when comprehensive revisions introduce many new goods and change the weights.

Deliberate changes may also be made in the quality priced if the volume sold indicates a change in consumers' preference. When this is done, the new quality is usually linked in. During World War II this practice was modified because of what was called "forced uptrading." A given quality of product formerly priced for the index might have been dropped because it had almost or completely disappeared from the stores, and been replaced by one of a higher quality. This shift was in part the result of price controls so that the market did not respond as formerly to consumer demand for given qualities. When it seemed probable that consumers were forced to buy the higher-priced line, a part or all of the price difference between the "old" and the "new" quality was included in the index.

Constant study of price movements is necessary since the ability of one item to represent another may change. The use of food subsidies during World War II led to careful scrutiny of items priced. A change in customary relations may necessitate the inclusion of additional items and the redistribution of weights. At one time the price movement of children's clothing was represented by that of adults. A change in the correlation of their prices resulted in some items of children's apparel being added during 1947. Because rents and the cost of housing to home owners had tended to move together, rents paid by tenant families were used to represent the change in housing costs of home owners. During World War II, partly because of rent control, this relationship changed. After the 1953 revision, change in rent no longer represented change in the cost of owner occupancy of dwellings.

During World War II and early postwar years rent control resulted in a downward bias in the rent index that came to be referred to as the "new unit bias." Normally in a market free of rent control the cost of new units and existing units of comparable quality is the same. With rent control a difference occurred. The rent index rose 6.8 points in Jan. 1950 when a correction for this bias was applied.

In the C.P.I. an attempt is made to measure price change only. In order to do this, specifications are set up so that the product priced in successive periods is similar if not identical in characteristics. Those for a man's shirt, for example, designate thread count, stitches per inch and character of workmanship. Such specifications for the most part are broad and their use in pricing often necessitates judgment on the part of the agent who inspects the product and obtains the price. Even so they serve to exclude from the index some of the effect of shifts to a higher or to a lower quality that may occur because of change in real income or preferences. This aspect of the index is often passed over lightly if mentioned at all in theories of price measurement. It presents many difficult problems in actual practice. What, for example, is an "identical" woman's hat in two successive seasons? Where is the identical automobile to be found when each year brings a new model? Those pricing women's hats must decide on what is comparable in the midst of changing materials, shapes and workmanship. Standard models of selected automobile companies are used and the significance of improvements from year to year is ignored—even those that lead to a longer life of the car.

Before 1943 rents for the index were obtained from rental agencies. Because of the possibility that violations in rent ceilings were occurring and might not be reported by rental agencies, a change was made in the method of collecting data. A sample of rental dwellings was drawn and rents were obtained from their occupants. Because of the high cost of drawing an entirely new sample, the same dwellings were priced in many successive periods. During World War II the "little steel" wage formula of 1942

brought the index into great prominence. Between Jan. 1, 1941, and May 1942, the C.P.I. increased by about 15%. The formula limited wage increases to 15% of wages prevailing Jan. 1, 1941, apart from inequities arising from unusually low wages. Claims for wage increases beyond this 15% were made on the grounds that the C.P.I. understated the rise in the cost of living. The members of the American Federation of Labor (A.F. of L.) and the Congress of Industrial Organizations (C.I.O.) in Jan. 1944 claimed that the cost of living had risen 43.5% during a period when the C.P.I. showed an increase of 23.4%.

Early in 1943 the American Statistical association appointed a committee to appraise the C.P.I. A downward bias was reported but no estimate of its magnitude was given. In the fall of 1943 the president's committee on the cost of living was appointed with William H. Davis as chairman and with employer and union representatives. Davis appointed a technical committee to review the index with Wesley C. Mitchell as chairman. The guesses of this committee put the total downward bias at from three to four points for the period Jan. 1941 to Sept. 1944. For about three years the BLS with each month's release explained that "the index does not show the full effect on the cost of living of such factors as lowered quality, disappearance of low-priced goods, and forced changes in housing and eating away from home." One outcome of the controversy was a change in the name of the index from "index of the cost of living of wage earners and lower-salaried workers in large cities" to "consumers' price index of moderate-income families in large cities."

The C.P.I. was used in wage negotiation in peace as well as war years. General Motors and the United Automobile Workers in May 1948 agreed upon an escalator clause that adjusted wage rates up and down with the C.P.I. For a time escalator clauses were quite popular. At the end of the Korean war their use dropped markedly. The proportion of workers under contracts with escalation clauses, however, seems to be closely related to price changes. In 1960, 2,600,000 had such contracts and, in 1965, 3,700,000. In 1965 these represented 5% of the labour force, mostly employed in the manufacture of automobiles.

Many modifications and supplements for the index were proposed. Some argued that fixed weights over a long period of time were inappropriate in a rapidly changing society, and recommended a chain index with the items and weights changed annually. The need was expressed for a C.P.I. for low-income urban families. There was evidence that during inflation prices of goods customarily purchased by low-income families tend to rise faster than those of moderate-income families. There were also proposals that the mobility of population be allowed to affect the index. In 1951 the index measured price change at a given location and ignored the differences in prices paid by families moving among cities with different price levels. Those who wish an index as a deflator of national consumer expenditures to measure the change in volume of consumer goods would like to have the entire population included. However, consumer price indexes useful for one purpose might not be suitable for another. Several consumer price indexes are needed if all purposes are to be served.

Other consumer price indexes include that of the National Industrial Conference board, a private agency representing employers, which has provided an annual series since 1914. More cities are included than in the C.P.I., but fewer items are priced. The U.S. department of agriculture provides an index of "prices paid by farm families" from 1910 forward. It is a part of the formula to measure "parity" income for agriculture. The items included are those typical of farm-family consumption during 1922-24. The index is confined to food, clothing and housing. Prices are reported by mail by retailers selling to farm families. No attempt is made to relate prices to the same quality in each reporting period, and prices reported are those most frequently paid for specified consumer goods. If higher or lower real income leads to a change in quality purchased this shift is reflected in the index. These three indexes have much the same cyclical pattern but differences in items, weights, areas and system of price collection are such that none of them can be used as a check on the accuracy of another.

**How Much Does It Cost to Live?**—Putting this question to a random sample of families would undoubtedly elicit answers highly correlated with their current expenditures. Outlays to provide things considered essential by a family tend to be its measure of its cost of living. Thus, higher income tends in time to bring a higher "cost of living," since essentiality is determined in large measure by that to which a family has become accustomed. Conversely, continued experience with a lower income will lead to a decline in what a family looks upon as its cost of living. The measurement of cost of living, apart from such individual judgments, is essential in the administration of relief, is implicit in social insurance, minimum-wage legislation, family allowances, income-tax exemptions, and has a place in wage negotiations. Cost of living in relation to the productivity of workers has also received scattered attention, especially the cost of education and health services.

Both governmental and nongovernmental agencies have provided measures of cost of living. Among the latter are some labour unions, the National Industrial Conference board and the Heller Committee for Research in Social Economics of the University of California. The Heller committee provides such measures for three occupational groups.

An essential first step in measurement is to decide on the level of welfare to be provided. The concepts used lack precision, although there is a consensus that "subsistence" is appreciably lower than "health and decency." When the level of budget is decided, it is next necessary to select the items and their quantities. Methods for doing this are not standardized. Quantity budgets for the most part have been set up by experts acquainted with the conditions of living of the group to whom the budget is to relate and having some survey or other data about current consumption. In selecting the items they take into account what scientists have to say about adequate diets and other conditions necessary for a high level of physical health, legal requirements (for example, those relating to sanitary facilities of dwelling and extent of overcrowding), the need of families of sociability and of children to go to school. The BLS statistics in the "city worker's budget of 1948" used another method. It selected the items and their quantities on the basis of the relation of rate of increase in quantity purchased to the rate of increase in income of families. The budget was at the income level where the relative increase of quantity in relation to income, technically described as income elasticity, was at a maximum. This was accepted as a measure of relative urgency felt by the families for the various goods.

The early measures of cost of living were concerned with poverty. After an extensive investigation, Robert C. Chapin decided that the annual cost of subsistence was \$800 for a family of five persons in New York city in 1909. At the close of World War I several budgets bearing on wage negotiations were set up, concerned with local situations only. In the middle 1930s the Works Progress administration set up two budgets to meet basic maintenance and emergency standards. These were priced in 59 cities. For the first budget the average cost for a family of four in 1935 was \$1,261 and for the second \$903. The maintenance budget was described as not so liberal as that of a health and decency level but above "minimum of subsistence." The emergency budget was looked upon as suitable only for temporary conditions. During 1939 and again during 1941, the BLS priced the maintenance budget in many cities. The city worker's budget of 1948 was developed by the BLS at the request of a congressional committee on appropriation "to find out what it cost a worker's family to live in large cities in the United States." The budget set up was described as an attempt to measure "a modest but adequate standard of living," for a family of husband, wife, a boy of 13 years and a girl of 7 years. The BLS estimated costs of this level of living in 34 cities during March 1946 and June 1947. At the later date the cost ranged from \$2,734 in New Orleans, La., to \$3,111 in Washington, D.C.

A need varies greatly among families. Thus, a budget designed to measure the cost of living for one family type is not suitable for others. In order to deal with this variation, early investigators set up cost scales for individual members based on age, sex and

TABLE II.—Scales for Families of Varying Size

Item	Adequacy of diets	Amount of savings
2 persons . . . . .	85.1	66.4
3 persons . . . . .	81.7	84.4
4 persons . . . . .	100.0	100.0
5 persons . . . . .	114.8	114.1
6 persons . . . . .	128.6	127.0

activity. In most of these, family need was measured in terms of adult equivalents, the need of an adult male being counted as one and that of other family members being expressed in terms of it. Food scales were most widely used, based on scientific findings as to need for nutrients and customary food patterns. The scales for other budget categories do not have so sound a basis. Furthermore, the scales for total consumption become complex when an attempt is made to take into account the economy that comes with larger size of consuming unit. This differs greatly for example, between food and housing. The BLS in publishing the city worker's budget in 1948 provided an over-all scale for estimating the difference in the cost of the budget for families of varying size if the same level of welfare was provided. Two criteria were used: (1) the relative income level at which families of various sizes report a specified quality of diets; and (2) a given amount of savings. The scales are given in Table II.

Budgets were also prepared for other types of consuming units. In 1948 the Federal Security agency published a budget to use in appraising the adequacy of the consumption of elderly couples living by themselves. As of June 1947 its annual cost in eight cities ranged from \$1,365 in Houston, Tex., to \$1,767 in Washington, D.C.

Budgets to measure the cost of living of single women became necessary because of minimum-wage laws. By 1948 cost-of-living budgets had been developed in ten states and the District of Columbia. In Massachusetts a budget for a single man as well as woman was set up and priced. In general, these budgets were for a single woman living away from home; employers argued that such a budget should be for a woman living at home. On the other hand, the U.S. women's bureau argued that allowance should be made for dependents.

**Place to Place Differences.**—Comparison in the cost of living between two places is simple if one budget represents the same level of consumption in the two places, but this condition seldom occurs. There may be differences in climate that affect need, in market prices that affect the relative quantity of various purchased goods and in the combination of adults and children in the consuming units that affect economy of consumption. All of these factors make it difficult to prepare budgets to represent comparable levels of consumption. The city worker's budget of 1948 varied the quantity weights for the clothing and housing in order to take account of the difference in climate among the cities in which it was priced.

Attempts were made to compare the cost of living of farm and urban families. One such measure was made by Nathan Kofsky. Two budgets were used and priced in both markets. City prices as relatives of farm prices using farm expenditure weights were found to be 30% higher, whereas farm prices as relatives of city prices using city expenditure weights were 12% lower. If two budgets could be developed to provide equivalent welfare, each could be priced in its own market and a single measure of cost of living secured. Suitable methods for this type of measurement had not yet been developed in the early 1960s. (See also BUDGET, FAMILY.) (M. G. R.)

#### SOME COMMONWEALTH COUNTRIES AND IRELAND

**United Kingdom.**—From 1914 to June 1947 the ministry of labour calculated a cost-of-living index at monthly intervals with 1914 as base year. The "weights" of the index were based on the average expenditure of 1,944 urban working-class family budgets collected by the board of trade in 1904. It was assumed that the proportions of total expenditure devoted to different goods and services remained unaltered until 1914. The average weekly expenditure of these families in 1904 was 36s. 10d., of which 22s. 6d. was spent on food. The weights allotted to the different groups of

items were 60% for food, 16% for rent, rates, etc., 12% for clothing, 8% for fuel and light and 4% for other items.

In 1937-38 the ministry of labour carried out a household budget inquiry to gather data for a review of the basis of the cost-of-living index (see *Methods of Measurement*, above). Most of the households were those of persons insured against unemployment but some of the uninsured workers in the same class were also included; e.g., domestic servants, police, etc. The scope of the inquiry covered agricultural workers and workers in industrial, commercial and clerical occupations. The average weekly expenditure of the industrial households was 85s. and of the agricultural households 57s. 4d. (*Ministry of Labour Gazette*, Dec. 1940 and Jan. 1941).

The outbreak of World War II prevented any immediate action, but in March 1947 the Cost of Living Advisory committee, which had been appointed in 1946, issued its report (Cmd. 7077, 1947). The committee recommended the institution of a temporary index based on the pattern of expenditure disclosed by the 1937-38 working-class budgets. Meanwhile, study of the problems of collecting a regular series of budget studies was to go on so that the form of a permanent index could be decided. Accordingly, an "interim index of retail prices" was calculated and was published at monthly intervals from June 1947. The groups of this index were eight in number and their weights were 34.8% for food, 8.8% for rent and rates, 9.7% for clothing, 6.5% for fuel and light, 7.1% for household durable goods, 3.5% for miscellaneous goods, 7.9% for services and 21.7% for drink and tobacco. In the 1937-38 budgets it had been shown that items attracting 22% of total expenditure were not covered by the old cost-of-living index.

The course of the old cost-of-living index during and after World War II may be compared with that of an index calculated by R. G. D. Allen using the weights of the interim index (*London and Cambridge Economic Service Bulletin*, Feb. 1949). Both indexes were computed on the basis 1938=100.

Table III clearly shows the effect of government policy of subsidizing those articles of consumption that entered the old cost-of-living index.

TABLE III.—Comparison of Cost-of-Living Indexes

Year	Cost-of-living index	Allen's index
1939	101	102
1940	118	110
1941	127	130
1942	128	130
1943	127	143
1944	129	146
1945	130	148
1946	130	150
1947	130	160
1948	—	173

Dudley Seers attempted to calculate the increase in the cost of living of the middle classes during World War II (*Bulletin of the Oxford Institute of Statistics*, Aug. 1948). He defined the middle classes as those with salaries of more than £250 per year in 1938, proprietors of business and those living on investment income (other than retired members of the working classes) together with their dependents. He further distinguished the lower middle classes from the upper middle classes by considering those with salaries of between £250 and £500 a year and those whose professional earnings or profits from farming, shopkeeping, etc., or investment income were less than £500 a year in 1938 as being the lower middle classes. Seers estimated that whereas the working-class cost of living had risen 61.2% between 1938 and 1947, for the middle classes as a whole it had risen 77.8%. Further, if the middle classes were divided, the rise between 1938 and 1947 amounted to 66% for the lower middle class and 85% for the upper middle class. These estimates are somewhat hazardous because of the method used to estimate the weights for the middle class indexes.

In June 1951 the Cost of Living Advisory committee recommended that a new full-scale budget inquiry should be held as soon as possible since conditions of spending appeared to be sufficiently stable. In March 1952 the committee reported on its investigation into the working of the interim index and suggested

modifications in the weighting structure of this index, to be based on the 1950 pattern of consumption as revealed by national income estimates, until such time as the new inquiry could be completed. The new index took Jan. 1952 as 100 but the all-items index was also linked to the interim index. The weights used for combining the proportionate changes in prices after Jan. 1952 were: food 39.9%; rent and rates 7.2%; clothing 9.8%; fuel and light 6.6%; household durable goods 6.2%; miscellaneous goods 4.4%; services 9.1%; alcoholic drink 7.8%; tobacco 9.0%.

The committee reported again in March 1956 when the results of the budget inquiry held between Jan. 1953 and Jan. 1954 had been analyzed. The new index was based on Jan. 1956 as 100 but as before the all-items index was linked to the interim index. The weights, as of Jan. 1956, for the new index were: food 35.0%; alcoholic drinks 7.1%; tobacco 8.0%; housing 8.7%; fuel and light 5.5%; durable household goods 6.6%; clothing and footwear 10.6%; transport and vehicles 6.8%; miscellaneous goods 5.9%; services 5.8%.

Particular attention was paid to the problem of obtaining adequate information about changes in rent, both of local authority houses and privately owned houses. After the Rent act, 1957, the sample of dwellings was increased from 2,200 to about 6,000. Quotations for food prices and for a number of other goods were obtained from retailers in 200 representative towns, while for furniture and various household appliances information was provided by agents who visited retailers in about 23 large urban areas. The ten groups of the index were divided into 91 separate sections, for each of which a number of items were priced monthly with a total of nearly 350 items.

In the annual government publication *National Income and Expenditure*, indexes are published of the market prices of groups of commodities based on the current pattern of expenditure of consumers of all classes. The recent course of the index referring to consumers' expenditure in the United Kingdom is given below:

Year	1950	1951	1952	1953	1954	1955	1956	1957	1958	1959	1960
Index	83	91	97	98	100	103	108	111	114	114	115

Further details about the interim and new indexes may be obtained from *Interim Index of Retail Prices* (H.M.S.O., 1952), *Report on the Working of the Interim Index of Retail Prices*, Cmd. 8481 (H.M.S.O., 1952), *Report on Proposals for a New Index of Retail Prices*, Cmd. 9710 (H.M.S.O., 1956) and *Method of Construction and Calculation of the Index of Retail Prices* (H.M.S.O., 1959).

**Republic of Ireland.**—In Nov. 1953 a consumer price index replaced the interim cost-of-living index (essential items), which had been published since Aug. 1947. The index covered all non-agricultural households and its weights were based on a family living study conducted in 1951-52. In this study 3,000 households reported their expenditure over a period of one week in each quarter of the year. Investigation showed that different types of families had reasonably consistent expenditure patterns.

The prices of 191 items were collected once every quarter in 118 towns and villages. Over 30,000 individual price quotations were used for each calculation of the index. A special rent inquiry was conducted annually in mid-November to obtain information about the rents and rates paid for rented dwellings, both local authority and privately owned. Allowance was made for the rates paid and the maintenance costs incurred by owner-occupiers. The prices of milk, eggs and potatoes were adjusted for season by correction factors based on the average seasonal movement over the preceding five years. The new index was linked to the old interim index but no official backward revision of the earlier index was made. The weights of the groups were as follows: food 40.8%; clothing 12.7%; fuel and light 7.0%; rent 6.2%; and miscellaneous 33.3%.

**Australia.**—The index used from 1953 was not based on a budget study but on national consumption data for the years 1950-53 as derived from consumption estimates using official production and trade figures, the census of retail establishments and general census data. Prices were collected for 245 items in each of six state capital cities. For commodities, prices were obtained generally from not fewer than ten retail outlets in each city. Information about rents was derived from a 5%-15% sample survey of four- and five-room brick or wood dwellings. A

six-city index of each item was obtained by weighting each city price-relative (the current price of an item as a percentage of its price in some base year) by its population. In the base period of July 1952 to June 1953 the weights allotted to each commodity group were: food 37.1%; clothing and drapery 26.8%; rent 9.0%; fuel and light 4.6%; miscellaneous 22.5%.

**Canada.**—A budget study was conducted in the year ending Aug. 31, 1948, in which records of expenditure for 3,600 families were obtained. The families represented all sectors of Canadian nonfarm population. For the compilation of the index 1,517 budgets were used belonging to families (1) who lived in cities with a population of over 30,000; (2) whose size ranged from two adults only to two adults and four children; and (3) whose income in the survey year was between \$1,650 and \$4,050. In fact, 45% had incomes between \$2,000 and \$3,000.

The year 1949 was chosen as the base period and the index included 224 items, 40% more than the previous index. Price quotations which could be collected by mail were obtained from 33 cities, while for articles which might be subject to quality changes the quotations were collected by full-time agents in eight cities. For each item individual price quotations were weighted by the volume of sales of the retail outlet concerned to derive the average price for a given city. The city average prices were then combined according to the relative importance of the article's sales in each city. Varying monthly weights were used for items the consumption of which fluctuates seasonally, such as fresh and canned fruits and vegetables, fats, eggs and meat. Expenditures such as property insurance and prepaid medical care were included in the index, but life insurance premiums were excluded.

**New Zealand.**—From 1956 the index was based on the postwar urban expenditure pattern, with the period Jan.–March 1948 as base. A total of 306 items were included in the index and prices of commodities were collected from 503 retail stores in from 10 to 21 towns with a 1948 population of 6,000 or more. Rent data covered 10,200 private houses, 25,800 state houses and 5,400 flats.

The weights for each commodity group in the base period were: food 32.3%; housing 15.4%; household operation 10.6%; clothing and footwear 15.4%; transportation 8.7%; miscellaneous 17.6%.

Table IV gives the movements of the cost-of-living or retail price indexes in various countries before World War II and from 1952–60.

**COSTUME:** see DRESS.

**COSTUME DESIGN, THEATRICAL.** The purpose of theatre costume is to separate actors from audience and to distinguish each actor from his fellows while they enact whatever it is the spectators have come to see. The actors' garments may be accurate versions of the clothing of some period; they may exaggerate or distort it; they may be primarily symbolic; or they may furnish an animal disguise.

#### WESTERN COSTUMES PREMEDIEVAL AND MEDIEVAL

**Premedieval Origins.**—Among primitive peoples the forerunners of true theatre are religious dances and other ceremonies; hence the earliest theatre costumes are religious. When a people's welfare is dependent upon the caprices of nature, interpreted as the granting or withholding of favours by the gods, ceremonies of propitiation take on various forms: imitative movements such as a rain dance, acts of commemoration that repeat some important happening of the past or impersonations in which the actor becomes for the time being an animal, a tribal hero, a god. The individuals chosen to enact these ceremonies renounce their own personalities temporarily and don garments appropriate to their roles. From such pretheatre beginnings of costumed action developed the great drama of Greece, but in many parts of the world the theatre still has not taken the final step into drama.

**American Indian.**—In the United States the Pueblo Indians of the southwest are a case in point. Their unique culture was arrested by the coming of the Spanish in the 16th century, but these people steadfastly preserved their symbolic ceremonial dances with the traditional costumes in the face of an alien and conquering religion. These costumes include garments of the style worn before the conquest: for men a wrap-around or kilt woven of heavy cotton, for women a drapery equally simple but more enveloping. (Such reverence for and symbolic use of garments formerly worn by all is a persistent characteristic of theatrical costume everywhere.) These particular costumes are decorated with highly abstract, symbolic designs. Along with the basic dress or sometimes instead of it may be worn ornaments and accessories that suggest an animal to be honoured or propitiated.

The eagle dance costume of the Hopi tribe includes wings with which the dancer imitates the swooping motions of the eagle and a headdress that symbolizes that bird. The Hopi eagle dancer wears a mask-headdress of more than human size, of highly unrealistic design, symbolic not imitative—actually a sacred symbol.

In the same category is the Shalako mask, which in the Zuni tribal ceremonial represents an ancestral spirit with "god-like potency." For, as Virginia Roediger explains, "As soon as the impersonator dons the mask of the supernatural he is believed to become that spirit. As a consequence he is supernatural and must not be approached or touched during the ceremonies and must be uncharmed before he again becomes mortal." Body paint also has magic power: it too renders the wearer untouchable and must be washed off ceremonially before he again becomes as other men.

Outsiders unaware of the important ritual meanings in the Pueblo ceremonial are stirred by the aesthetic appeal of the costumes: their vibrant colours, ingenious construction, abstract designs pleasingly applied and such ornaments as sashes, fringes, tassels and rattling shells that combine in a syncopated accompaniment to the basic rhythm of the measured steps.

**Egyptian.**—From such dances and other primitive religious embryo dramas, scholars infer that similar conventions developed in prehistoric civilizations. The rather sketchy information available about Egyptian theatre in historic times points the same way. Scripts of a few Egyptian religious plays do exist but there is no indication of the costuming. However, many Egyptian figures in stone, in fresco and on papyrus have the look of theatre costume designs: hawk-headed men in loincloths and round beaded collars; female figures wearing headdresses representing the folded wings of birds, their bodies wrapped in feather-painted skirts, and many others, beautiful now as pure design, once charged with symbolic beauty as well.

Those animal heads could well be the masks of priests impersonating gods. Certain to be identified as elements of priestly costume concerned with ritual are the false ceremonial beard (also reserved to the Pharaoh) and the exotic leopard skin drapery so alien to the ordinary dress of a tropical people. Here consideration of Egyptian theatrical costume must rest until more evidence comes to light.

**Greek.**—Egypt was one of the contributors to the religious thought of Greece. Another was Thrace, whence the god Dionysus came rioting down. With the worship of Dionysus began Greek drama, lusty with satyrs and dancing women. The satyr impersonators, who formed the first choruses, imitated nature creatures with hairy legs, bushy tails and animal-like masks. Long after the form of the ritual song-dance had been subordinated to developed drama with choruses of various sorts, the satyr play lingered on, as though men were loath to give up the opportunity to identify themselves with the wild things by means of masks and tails. The mask, then, is the first important item of Greek theatrical dress. Also associated with Dionysus is the non-Hellenic tunic, the distinctive garment of the dramatic hero who emerged in the time of Aeschylus. This tunic was characterized by its length (to the feet); sometimes by a train called the *syrrma*, which was added occasionally for special emphasis; its slight shaping to the form; its long, snug-fitting sleeves; and its lavish ornamentation. This garment, of Thracian or possibly Persian origin, is an

early example of the ever-recurrent tendency in theatrical costume design to turn to the exotic, the foreign. No costume could have been further removed from the ordinary dress of the Greeks, whose principal garment was then the chiton, which in its pure form is never shaped to the body; it is a rectangle of wool draped upon the wearer and secured by pins and cords. It is never caught to enclose the arms snugly and often leaves them entirely bare. Men wore the chiton short, women wore it long.

The tragic actor's tunic was long probably because of the tradition that Dionysus himself wore a long dress. He also traditionally wore the cothurnus, a soft boot laced to mid-calf; this also became a part of the actor's costume. Aeschylus is said to have caused the boot (it was originally feminine footwear) to be modified with a hard sole that added to the wearer's height. Evidently this sole was thickened progressively, but when and by how much and to what ultimate thickness are matters of controversy. Early written testimony is ambiguous. Pictorial evidence for really high soles is scanty and late, dating from the early centuries of the Christian era and the decline of tragedy. From the beginning, however, the principal actors did wear masks, which almost immediately were accompanied by the headdress, or *onkos*. Together they served to identify and characterize the wearer, and in time both became more and more stylized and exaggerated. Mask, *onkos*, instep-length robe with long sleeves and lavish decoration, high boots with hard soles—by these distinctive details was the tragic actor set apart.

By contrast, the chorus appears to have worn chitons and these were made of the richest material and ornamentation the *chorēgos* could afford. The *chorēgos* was some wealthy Athenian who, since he had been accorded the honour of dressing these singers and dancers, would strive to live up to it by extravagant expenditure. When both chorus and principal actors needed to augment their costumes they put on the *chlamys*, a moderate-sized scarf, or the *himation*, a great enveloping length of fabric that served both men and women as an outside wrap.

Concerning colour symbolism on the tragic stage of the 5th century B.C., evidence is far from definite. In the works of art that yield information about Greek dress, including theatrical, virtually no colour remains. Passages quoted are generally from Pollux, who wrote 500 years later. Contemporary writing pays tribute to the "rich colours" worn by the actors and to the "sumptuousness" of the chorus. It states that gold threads were woven into purple cloth for royalty; red, ranging from purple-red to flame colour, was a hue for heroes; the drabs and black stood for poverty and grief. But decorative design and its motifs fared better: there still exists in vase painting a clear recording of the actor's patterned robes with their horizontal stripes, pointed rays, palmettes, spirals, heads of sphinxes, horses, human figures and the familiar wave.

Comedy, which also derived from the worship of Dionysus, followed the spirit of the funmakers rather than that of the more reverent worshippers. The costume of Old Comedy is far removed from that of tragedy. It was gross and clownish and sometimes inspired extra mirth by satirizing the dignity of tragic heroes and gods. The masks were exaggerated and ludicrous; when the wearer represented some contemporary poet or politician his face was recognized as easily as the faces in present-day cartoons. Masks survived into the later, realistic New Comedy of Menander; by that time they were no longer caricatures but merely types. Whereas tragic theatre dress was longer than ordinary, that of comedy was shorter; the tunic, whether sleeved or not, reached just to the buttocks. Ankle-length tubular pants covered the legs. Feet, though sometimes bare, were often dressed in the soft sock shoes or *soccus* that came to be identified with comedy as the cothurnus was with tragedy. The pants were wrinkled, sloppy laugh-getters. The whole figure of the comic actor was a grossly undignified contrast to the stately body of the tragic hero; he had shoulder humps, bumpy biceps and calves (or stringy arms and legs), and a huge belly balanced by great fat buttocks; and he always wore the phallus, stylized, greatly exaggerated, but recognizable. A leftover from the primitive once serious fertility rites, this appendage had come down via the satyrs. It eventually

disappeared from the sophisticated and realistic New Comedy but was retained by performers in the rustic Dorian Phlyakes. New Comedy, dressing its actors in ordinary clothes, clung to the mask, which still set the actor apart from his fellow Greeks.

**Roman.**—When republican Rome took over Greek drama, few alterations were made in costume except in the direction of lavishness; these changes were neither as important nor as extensive as the changes in staging. There existed, however, a native drama in republican Rome that was in the style of realistic Greek New Comedy, but with Roman plots; this drama had costume characteristics so distinctive that the name of the garment was given to each type of play. The dramas based on Roman history and its heroes were called *fabulae praetextatae*, the *praetexta* being the distinguishing purple border of the toga of magistrates. These honourable persons also wore the high boot (*cothurnus*), possibly with the sole elevated a few inches. The realistic comedies dealt with characters of all sorts.

In the *fabulae palliatae* (Roman comedy based on the Greek model), the actors wore the pallium, a cloak of everyday wear resembling the Greek himation. Actors in the comedies of both Plautus and Terence were costumed in ordinary clothes and wore the pallium. If they did not go barefoot, they wore the *soccus* or the *solea*. In the later form, the *fabulae togatae*, treating of ordinary Roman citizens in rural and small-town society, the Roman mantle or toga, as worn during the early period by all classes, was substituted for the pallium.

Some scholars, notably W. Beare, are convinced that from the

time of Plautus (3rd century B.C.) the actors in these original Roman plays wore masks, but this contention is vehemently denied by others, including Margarete Bieber, who holds that only facial paint and wigs proclaimed the actor's character. She concedes, however, that possibly in the 2nd century B.C. masks were used in the plays of Terence. All agree that Quintus Roscius, the accomplished actor of both tragedy and comedy in the time of Cicero, inaugurated the regular use in Rome of masks that, as in the Greek tradition, identified characters as old, young, master, slave, courtesan and so on. In imperial Rome both the mask and the *onkos*, worn in Greek-derived tragedies, were exaggerated to the point of exciting derision. It is from the viewpoint of this latter time that Pollux compiled his oft-quoted list of masks worn, he says, in Greek New Comedy.

Masks continued to be the one indispensable article of theatrical costume throughout the sordid history of the theatre in imperial Rome and Constantinople. The mimes who unfolded their story by means of speech as well as gesture wore the old-style masks with open mouths. Evidence suggests that sometimes facial paint was substituted, which would allow more freedom in expression. Regarding the rest of the costume little is recorded except that it became increasingly spectacular—and probably, like the plays, increasingly indecent. The pantomimists, who danced without words but with agile and expressive body gestures, wore a new kind of mask with closed mouth. About their costumes there can only be conjecture based on audience reaction recorded as approving (of rich fabrics and jewels) or disapproving (of lascivious design).

As to colour in the Roman plays, there would of necessity be the white of ordinary togas with, when called for, the purple of a *praetexta* border. Written testimony as to other colours comes from Pollux and from Aelius Donatus (they do not always agree). Purple is associated with royalty, of course, and also with the military: poor folk are allotted dull red; pimps (frequent characters in the comedies) are distinguished by "variegated colors"; and prostitutes by yellow, signifying greediness. Slaves wear red wigs. White is for old men but also for "a young man" and for "a cheerful person." Those frescoes and mosaics of the 1st century A.D. that represent scenes from plays show costumes in a variety of bright colours that did not, apparently, follow any symbolic conventions.

Alongside the Roman-Byzantine shows continued the *Atellanae*, the farces that had originated in the south of Italy as descendants of the Greek Phlyakes. The players of Atella developed a technique of improvised comedy in which the actors always were identified with certain typed characters in varied situations. Here are the prototypes of certain *commedia dell'arte* characters: Macchus the fool, Pappus the old man and particularly humpbacked hooked-nosed Manducus, who became Pulcinella and finally Punch, the rascally hero of the puppet show and the jolly reprobate on the cover of the English periodical.

The country improvisers held on, even after the vast metropolitan spectacles had died out under the disapproval of the church and the dwindling Byzantine power. Acrobats, jugglers and tight-rope artists scattered through western Europe, bringing their masks, foolscaps and even the shaggy skins inherited from ancient satyrs. They became well known at village fairs and showed up at castles, too. A few became domiciled as household jesters, complete with foolscap and sometimes bells. Such relics of the entertainer's arts preserved traces of theatrical dress. More important theatre costume then came into being along with the Christian drama as once again religion became the root of theatre.

**Early Christian Drama.**—The central ritual of the early church was the eucharistic feast, a shared commemorative partaking of the bread and wine. The ritual, an ordered sequence, was led by the priest, who thus became the protagonist, the leading actor in a sacred drama. Out of reverence, he wore from the beginning his best alba, a long, sleeved, generally white garment commonly worn in Rome during the empire. This is the ancestor of the alb, still a principal church vestment. To it were soon added other dignified Roman garments. Set apart by their use, the Roman vestments were retained after their secular origin had been forgotten (another instance of the persistent archaic element in theatre).

costume). Roman civilian dress thus became the costume of the Christian ritual drama. Hence when the first dramatic episode was interpolated in the Easter service, the actors found costumes at hand. The characters were the angel at the sepulchre and the three women who came to anoint the body of their crucified Lord. At a given moment a young man came from the choir and took his place at the tomb. He was already clad in his long white alb, suitable vesture for an angel. Now came the two Marys and the third woman, three more young men from the choir, also in albs. To complete their woman's costume they had only to lift the amice (large neck scarf) and put it over the head to become women. The playlet over, they returned to their places and their own personalities. From this simple beginning religious drama developed into a whole epic of mankind from creation to last judgment, but even after it had moved out of the church, priestly vestments were resorted to on occasion. For instance, the clergy of one cathedral gave permission to the townspeople to use a cope (rich cape) for

God the Father, "on condition that the play does not become dissolute."

**Medieval Developments.**—The medieval theatre, regardless of how faithfully its subject matter was taken from Holy Writ, was by no means only religious. Just as Greece had its satyrs and misshapen clowns, the middle ages had its devils. Some recall the old satyrs with shaggy goat legs, cloven hooves and horns; some developed new drolleries with bat wings and scorpion tails; some were embellished with ornaments on the knees, elbows and bellies as well as grotesque masks on the face. These devils were black, red or blue from head to foot. Herod, who ranked next to Lucifer-Satan as the archvillain, was likewise fitted with grotesqueries, including a great turban-crown and a mask with hooked nose and fanged mouth. Terrifying as these creatures were intended to be, they were also objects of mirth, as were other characters including Noah's wife and sometimes the shepherds. Usually the actors needed only face paint to emphasize natural en-

dowments; but when superhuman majesty was wanted, as for the Transfiguration, craftsmen devised an awe-inspiring mask and gilded it. The European craft guilds and the societies dedicated to producing the sacred dramas, as well as the leaders of the Italian city-states, strove to present their plays as factually and as sumptuously as possible. Surviving records—stage directions, expense accounts and chronicles—testify to expenditures for rich fabrics and gold leaf, and to the ingenuity of designers and craftsmen. No construction problems baffled them. They produced instantaneous transformations, talking beasts and practicable wings for angels as needed. The stage costumes were not only rich but also exotic. The costumer drew upon the past, especially antiquity, and upon the foreign, especially the tales of infidel Saracen and Turk, constructing rich and strange costumes from these partly understood sources. Throughout the later middle ages the costume parade included tyrants outfitted in papier-mâché heads, with scarlet wigs and beards, and crowns, turbans and robes that glittered with jewels; demons whose huge grotesque masks and lashing tails struck fearful pleasure to the hearts of the beholders; angels with shining garments and gilded limbs; and deity, towering above the restless crowd, immovably benign in a golden mask.

#### RENAISSANCE TO MODERN

**Renaissance.**—In the 15th century, northern Europe was still medieval, although by then the Renaissance was well launched in Italy; by the early 16th century both France and England were following the new ideas, at least in court circles. In the meantime, as morality plays began to supersede the drama based on religious stories, costumes became allegorical for Justice, Peace, Truth and the like. Such abstract figures began to assume an "antique" appearance as the classical Renaissance took firmer hold, and it was not long before the slightly classic robes of the Christian virtues were followed by similar robes for Jupiter, Mars and even Venus.

Except for the rural comedies and the somewhat literary farces played mostly in the universities, theatre in the 16th century found its outlet in the expensive show-off spectacles of municipality or court. First came the processional shows, called in England "progresses," in France *entrées* and in Italy *trionfi*. (The Italians wanted to believe that they were reviving the triumphs of ancient Rome, in which a victorious general paraded the streets

in a golden chariot, clad in purple and gold, crowned, preceded and followed by his royal captives in chains, his soldiers and his wagons of loot.) Actually the Italian street show, like *entrées*, celebrated the entry into a city of some important person and included that person, his entourage, the city greats and float after float of allegorical figures. The medieval combats at arms developed into shows that had rudimentary plots. These stage conflicts were grim contests in which costume pageantry was furnished by distinguishing colours, crests, plumes, shields and other paraphernalia of heraldry; they served as the excuse for dressing opposing horsemen in magnificent costumes of Turks, Crusaders, Amazons or "wild Scotsmen." Other outdoor spectacles furnished the opportunity for dressing actors in magnificent mythological, sylvan, pastoral and marine costumes. Top-grade artists designed these costumes as well as the scenic effects; among the designers

in France were Rosso Fiorentino and Francesco Primaticcio, Italians who brought Renaissance art to the north. In Italy itself all the artists were called upon to design costumes, from such Florentines as Giorgio Vasari, Jacopo da Pontormo, Bernardo Buontalenti to the great Leonardo da Vinci himself.

Outdoor spectacles made free use of masks, almost a necessity when men had to impersonate women. At court balls both men and women wore masks—not for magic or for character identification but for concealment. Presently the spectacle and the fancy-dress ball merged, women joined the performers, ladies and gentlemen learned to step through figure dances and the court ballet, the *ballet de cour*, was born. The Italians believed that in these musical spectacles they were reviving the Greek heroic drama. From court ballet developed opera, which has seldom lost sight of the original spectacular features, including costume. To be sure, the first opera ballets can most logically be better compared with the musical of modern times, particularly in the matter of highly spectacular costumes. The *Ballet comique de la reine* at the French court in 1581 is the example most often quoted, probably because there are a number of copies of the book, which records the production and includes costume pictures by the designer, Jacques Patin. These costumes, called "antique" like others of the time, are in reality very much in the current mode, with additions that suggest classical draperies. A nymph will not have abandoned her tight bodice and great puffed sleeves, but she will have added a billowing overskirt, gauzy oversleeves and a fanciful headdress from which floats (invariably) a chiffon veil. The male actor-hero, probably cast as a warrior, will be clad in a version of Roman style cuirass (body armour) over a doublet with the fashionable great sleeves, a classical helmet with impressive plumes (the panache) and Roman "labels" over his breeches and long hose. These labels were originally metal-tipped leather tabs that hung from the cuirass to cover the thighs. The Renaissance developed this useful accessory into a greatly exaggerated and ornately mounted skirt and named it the *tonnelet*.

While amateurs at European courts strutted and sang through ballet operas in costumes created at a cost beyond the reach of even a 20th-century Broadway musical, bands of professional actors in tradition-perfected costumes were making their way from Italy to other European cities and courts. The *commedia dell'arte*, grown in skill and sophistication far beyond the rustic improvisations of the *Atellanae*, clothed their well-defined characters in

the distinguishing garments that they were to retain through succeeding centuries, subject only to the dictates of changing taste. These are ideal theatrical costumes: they identify the characters, allow complete freedom for acrobatic dancing, exaggerate tellingly and delight the eye with bright colours and amusing patterns. Most *commedia* actors (except the lovers) wore half masks that emphasized the character.

There is little direct evidence that shows how the characters in the great plays written by Shakespeare and his fellow playwrights were dressed. Students of the theatre conclude that costumes at the Globe, for instance, were as handsome as the cash-box allowed; that they were often in the contemporary mode; that period such as Roman was indicated by classical and exotic details—togas, turbans, oriental-looking robes; and that when it came to fairies and such imaginary creatures, the wardrobe supervisor did his best to imitate the sort of "antique" creations that were being designed by Inigo Jones for Ben Jonson's masques at court. Jones had received his art education in Italy. His costume designs have a close affinity to those of Vasari. Fortunately, many designs by both Jones and Vasari are preserved along with written descriptions, so that costume plates for specific productions can be assigned to specific artists. These men of the late 16th and early 17th centuries had artistic stature. Their designs reflect the last stages of Renaissance classicism and form a transition to costumes of the baroque theatre.

**Baroque.**—The 17th century was a period of theatricality. Architects of palaces, chateaux and churches joined with sculptors and ornamentalists in producing effects boldly emotional, with sharp contrasts of light and shadow, the whole enriched by a profusion of C-curves, vines, flowers and human forms. The time was propitious for truly theatrical design, and the men for it were at hand. All the skills of stagecraft, including that of costuming, reached a high peak in the 17th century. From Italy came the Bibiena family, with their marvelous scenic illusions, and Giacomo Torelli, whose stage effects caused astonished Parisians to accuse him of practising black magic. Amid all this grandeur and complementing the painted backgrounds moved stately figures in rich, stiff fabrics hung with gold tassels and fringe and encrusted with gold and jeweled ornaments. Jacques Callot recorded these costumes as well as those of the *commedia*, whose types were thus set for later generations.

Heroic tragedy had its own costume conventions; these were established with the performances first of Corneille's classic dramas and then those of Racine. Actresses modified the current fashions with external touches of antiquity and enhanced their impressiveness with towering plumes. The tragic hero in his cuirasslike doublet still recalled the Roman warrior, but his headpiece was more frequently a plume-laden hat worn over a periwig than it was a helmet, and his *tonnelet* had widened into a heavily ornamented petticoat.

Molière devised brilliant shows for performance at the new royal residence of Versailles, his witty texts combining perfectly with the music of Jean Baptiste Lully and the décor of Jean Bérain. Courtiers acted in these shows along with professionals, and occasionally the king himself, Louis XIV, danced a ballet, dressed in a costume designed by Bérain. A great many of Bérain's designs have been preserved; all of them are supremely theatrical, supremely baroque. Inspired by visions of the past and of foreign lands, he designed costumes to be danced in, with swaying skirts, floating veils, flying ribbons, dangling tassels; costumes to spring in, with snug breeches, close caps and free-moving sleeves. He designed fairies and antique goddesses and savage chiefs of the Americas. Yet even his most fantastic designs are chic with the particular ornamental stiffness of fashion plates by Pierre Bonnard, his contemporary.

The actors in Molière's comedies, such as *Tartuffe*, played in contemporary dress, as did those in the English Restoration comedies. Drama had not yet retreated behind a proscenium arch; the actors playing on the apron were visible from three sides and were close to the audience, so that their clothes had to stand scrutiny. It was worthwhile to embroider intricate designs. The motifs, if bold, were no bolder than current taste allowed in

the gowns of their cosmopolitan audiences.

**Rococo.**—Early in the 18th century, Louis XV, in his turn, danced his ballet for the admiration of his subjects. His costumes and those of the ensemble were designed by the court decorative painters, such as François Boucher, Nicolas Lancret, Jean Marc Nattier and Louis Boquet—the last-named less important as a painter but a most delightful designer of costumes. Antoine Watteau, rather than designing for the theatre, painted the actors of the theatre—both the Italian troupe and the French comedians. He also painted imaginary actors dressed in costumes fancifully nostalgic and shown in amorous scenes, courtly or pastoral.

In theatre designs of the 18th century the pastoral influence often intrudes. In other eras countryfolk had been represented realistically on the stage as often as poetically, but in the rococo period they were all pretty, very very clean, clad in delicate silks, garlanded with flowers and carrying beribboned crooks. Two other influences on stage costume and interior decoration were the familiar antique and the Chinese, the latter enthusiastically discovered in the late 17th century and adopted into the essence of rococo. As for the antique, its real influence upon stage costume awaited the French Revolution.

Operatic costumes followed the mode into lighter fabrics and more delicate motifs, except that the *tonnelet* became larger and more ornate. A leading tenor depicted on the stage with his singing partner had his *tonnelet* looped and draped in silken swags as wide as her panniers, but knee-length instead of to the instep like hers. His wig is the fashionable close-curved tielwig; his hat a flourishing tricorn, plumed. Ballet dress as a special, functional stage costume was introduced early in the 18th century when the solo feminine dancer, who now performed light and intricate steps, had need of a shorter, lighter dress. Marie Camargo, as pictured by Lancret, wears skirts well above the ankle; here was the introduction of the distinctive ballerina costume that would be perfected in the 19th century.

**Empire.**—The French Revolution, with its wholesale imitation of the styles of republican Rome, exerted an influence on stage costume that was as profound as its influence upon women's dress. By the end of the 18th century actresses, along with the ladies in the audience, had discarded their impressive but cumbersome trappings such as panniers and high wigs and were playing neoclassic roles in neoclassic robes. Jacques Louis David, a painter deeply imbued with admiration for the classic, having managed to hold on from monarchy to directory to empire, set out to reform the male actor's attire, which had never relinquished the traditional *tonnelet* and other trappings. He persuaded the great actor François Talma to appear in one of his classical roles in a Roman-style *tunica* minus *tonnelet* and stockings. Now the men of the new era, who had not followed their womenfolk in adopting Roman dress, were coated, high-collared and pantalooned to the ankle. Consequently neither men nor women in the audience took kindly to bare shanks on the stage. Throughout the rest of the 19th century and even into the 20th Romans in reasonably authentic tunics and togas continued to step out in snug tights, not always flesh-coloured.

**19th Century.**—The antique as a fashion did not last long in the 19th century; in the succeeding romantic period stage costumes followed the current mode: drop-shouldered décolletage, snug bodice, bell skirt. The early part of the century also brought something new to the costuming of any period play—a conscientious obligation to revive the dress of the period portrayed. In England the pioneer in this attempt at historical integrity was James Robinson Planché. Although the libretti he wrote and staged for Mme Vestris, the dancer, were feeble imitations of rococo, he established his place in theatre history by writing one of the first and most reliable histories of costume and, even more, by dressing King John for Charles Kemble in 10th-century garb based on manuscript pictures and sculpture contemporary with that chronicle play. That was a milestone in theatre history truly exciting in its own time. The 19th century witnessed a growing interest in archaeology of all kinds. Out of it came, for one thing, the publication in England, France and Germany of other scholarly histories that still form the basis of a costume designer's library.

But time has proved that historicity is not enough to ensure the success of a theatre costume, mainly because the time element always stands between the present and the past. No costume designer, costume maker or actor can escape it. For instance, from the earliest years of Victoria's reign to the death of Edward VII the fashionable female figure of the entire urban world was amply boned, padded and petticoated; the male counterpart was encased just as completely if not so tightly constricted. The result for all branches of the theatre except ballet was that bodies were corseted in the Victorian mode as a foundation for such varied period costumes as those of Calpurnia in *Julius Caesar*, Norma in the druidical opera, Francesca da Rimini in the popular play by Bokar and Beatrice in *Much Ado About Nothing*. No amount of authentic ornamentation or accessories could transform the wearer into a figure from the past. No wonder later generations found the accurate reproductions from Victoria's reign stuffy, overelaborate, unimaginative, boring.

Later, in the 20th century, when modern art had changed

even philistine ideals of beauty, the once-admired archaeological approach to costuming the classics was thrown out along with the old-fashioned corsets. Even such epoch-making costumes as those designed for the spectacular Wagnerian operas seemed in retrospect far less pre-Romanesque than mid-19th century German. Nevertheless, some costume rental establishments continued for years to stock and send out to amateur groups those sturdily constructed relics of the past that can best be labeled costumer period.

Meanwhile professionals in the lighter forms of entertainment dressed as always in costumes that met the time-tested essentials of theatre: construction that permits free movement, eye appeal through exaggerated motifs, striking colours, sequins, plumes, trains and display of as much of the feminine figure as is countenanced by the local mores; and somehow through it all large concession to the contemporary mode. The improvised comedy, which had dwindled to insignificance as a dramatic form, bequeathed to the popular theatre certain characters and their costumes. Pierrot, once an unimportant member of the *commedia* troupe as a stupid, hayseed type, was transformed by the French pantomimist Jean Gaspard Debureau into the pathetic lover, white-faced, black-capped, in droopy white garments, eternally mooning over Columbine. She herself developed from a second-class soubrette to a leading dancer in the short, fluffy skirt of ballet. Harlequin, always clever, became the leading figure of English light entertainment. Many versatile actors were famous for their dancing Harlequins. Under a variety of names and embellishments he was always fundamentally a lithe, sleek figure in diamond-patterned tights and a neat black half mask. He brought along the bat that he had inherited from the forgotten *Atellanes*, the same bat that medieval devils had flourished in the old guild plays. Other descendants of ancient buffoonery are the whole tribe of clowns familiar in the English pantomime, the circus and vaudeville. However varied the clown costume, from comic elf to hobo, the constant feature is grotesque make-up. A mask of paint, rather than the inflexible mask of the ancients, often recalls the old comic masks with their great noses, huge eye sockets and enormous, wide-lipped mouths. A unique American contribution to the ancient line of clown masks is the burnt-cork minstrel show face, a stylized exaggeration of African Negro features.

#### 16TH-CENTURY COSTUMES

(Left) Pastoral costume design by Leonardo da Vinci for the "Festival of Paradise," an Italian court pageant; 16th century; in the Royal Library, Windsor Castle, England. (Right) King Henry III of France dressed in an "antique" costume of a warrior for a court masquerade. Detail from the "Quintain," one of the Valois tapestries; about 1580; in the Uffizi Gallery, Florence

(LEFT) BY GRACIOUS PERMISSION OF H.M. QUEEN ELIZABETH II; (RIGHT) BY COURTESY OF SOPRINTENDENZA ALLE GALLERIE, FLORENCE

Most important in the 19th-century theatre was the evolution of the classical ballet, which developed a costume of its own that was both functional and aesthetically satisfying. When the dancer went up on *pointes* (the toes), she seemed to scorn the ground, each of her technical tours de force contributing to that illusion. Her costume always enhanced this denial of gravity, from the calf-length tarlatans of Carlotta Grisi in 1804 to the thigh-short tutu of Anna Pavlova. Perfectly adapted to its function, the tutu with its accompanying sleek bodice epitomizes the flight from reality to the dream world existence of classical ballet. Under its spell the 19th-century moderns painted the art of ballet, for Renoir, Seurat and the rest were not so much interested in designing ballet costumes as in painting girls in them. (To be sure, Pablo Picasso was still a modern in the 20th century; at that time he did make costume designs for a number of ballet-operas, and so did his younger contemporaries.)

Famous throughout Europe from about 1875 to 1890 were the productions of the repertory company organized by George II, the duke of Saxe-Meiningen. He designed costumes for his own productions that set a new standard of meticulous authenticity and excellent craftsmanship. Fastidious good taste was equally the mark of Sir Squire Bancroft's London company that played popular drawing-room comedies in smart contemporary dress. Everywhere the standard of theatrical production went up. The conservative leading artists of the late 19th century in England included among their activities the designing of both scenery and costumes. They brought to the task erudition and the techniques of painting, though not always theatrical sense. Impressive certainly were the costumes designed and constructed for the spectacular productions of such actor-producers as Sir Henry Irving and Sir Herbert Beerbohm Tree.

**Modern.**—As the 19th century approached its close and all visual arts stirred in rebellion against the long-established post-Renaissance representational ideal, the theatre began to be bored with established production methods. As always at the beginning of any revolutionary movement the ordinary theatregoer was slow to notice the new trends, but even before World War I enthusiasm had begun to spread from a few young students of the theatre to a wider public. Perhaps the biggest jolt to conventional minds was the Russian ballet with its costumes (and of course décor) designed by Leon Bakst. In contrast to the older designers and their polite but tired palettes, he threw upon the stage explosive and barbaric colours, piling colour upon colour, motif upon motif in oriental profusion. His drawings leaped from the paper just as the dancers whom he dressed leaped about the stage. Starting with folk costume or historic dress he exaggerated, intensified and distorted to express the meaning of the dance dramas. Even timid young theatre workers caught fire from him and dared to combine orange and watermelon pink.

Other influences tended to counterbalance the Russian frenzy. Edward Gordon Craig revealed the virtues of lofty and uncluttered surfaces, long grave lines and heavy fabrics; Adolphe Appia showed the way to creative lighting, and from him and his followers costume designers learned how to cope with light and take advantage of it. Max Reinhardt in Germany and the U.S. revived the splendours of the middle ages and the Renaissance. In his vast productions of *Jedermann* (*Everyman*) and *The Miracle* he drew upon modern techniques, the exaggerations of the Russians and the vast scale of Craig to recreate religious drama in terms acceptable to modern taste. In one version of *A Midsummer Night's Dream* he revived the baroque splendours of Vasari and Jones.

The new theatre artists were competent to create costumes of vastly different sorts to meet the demands of widely different plays. A designer might create in the baroque spirit for one play or in purest classical simplicity for the next, in each case dictated to only by his sensitivity to the needs of the play, his knowledge of art history and his feeling for design. Theatre, which had been in the 18th century the actor's province and in the 19th a ground shared by actor and playwright, bade fair in the early 20th to become chiefly a field of artistic expression for the designers of scenery and costumes.

After World War I, new developments in art were inevitably reflected in the theatre, primarily in a sophistication of colour and an extremely acute selectivity of line and mass. After achieving fame in other pictorial media artists might try their hand at stage décor and costuming. That boldest experimenter in new art forms, Picasso, created for *The Three-Cornered Hat* a set of costume designs as practical as they were stunning. Various artists well trained in the ateliers of Europe and New York adjusted their skills to the demands of the stage, as had their remote predecessors in the Renaissance. In general, costume designers succeeded in proportion to their experience in total theatre.

If any one artistic viewpoint proved more congenial than others in the first half of the 20th century, it was the baroque, as expressed in costume designs for romantic plays from or portraying the rococo 18th century, all periods of the 19th and the early 20th; all these designs, called respectively empire, early Victorian and Edwardian, were nostalgic stylizations of decorative elements that were admired in the world of yesterday. Such neobaroque designing found its richest opportunity in the newer music theatre, which was developing the haphazard song-and-dance musical comedy into a well-plotted drama with integrated music and dance.

One theatre might house a sumptuous musical; the next, an experiment with classics in modern dress—an economical style of costuming that proved there is emotional significance in anything worn on the stage. Perhaps it was via modern-dress Shakespeare that the earlier revolt against a strictly archaeological approach to period plays reached the popular theatre of Europe and New York. If modern dress succeeded, then why not any period deemed suitable, or a mixture of periods? Eventually audiences saw characters in *Measure for Measure* dressed like those in *Lady Windermere's Fan* and actors in *The Taming of the Shrew* wearing the ten-gallon hats and leather chaps of pioneering Texas. As a rule the ephemeral appeal of novelty was backed by the solid worth of good design, for costumers after mid-century generally were well-trained, creative and knowledgeable.

## EASTERN COSTUMES

Throughout the thousands of years during which occidental theatrical costumes developed, fell into disuse and were revived in other forms, the costumes of the eastern theatre showed very little change. Drama itself was a more conservative art in the east, leaning to formalism in acting and staging and therefore in costuming. To western eyes the eastern costume never seems realistic, not even in the popular dramas with domestic plots. It is always primarily theatrical.

**China.**—In China the theatre is of extremely ancient origin and as elsewhere has its roots in religious ritual. It has been a popular art for centuries, and the conventions of its staging, acting and costumes have been well understood by the average playgoer. Headdresses, for instance, indicate clearly not only social caste but even the character's place in the plot. Thus costumes besides being ornate, are also functional and highly important in communicating the story to the audience. In some plays and for some characters masks are worn; e.g., to portray the supernatural or some part that requires extra emphasis. Generally, however, character make-up is achieved by using symbolic colours and lines, with the addition of appropriate wigs and beards. Female impersonators in the all male cast rely entirely on exquisite make-up and a body trained in the quintessence of feminine grace essential to wearing their lady robes.

**Japan.**—In Japan masked temple dancers preceded the *nô* drama, which itself was so intensely aristocratic that it was performed only under imperial auspices. *Nô* costumes, derived from ancient ritual and court ceremonial dress of the era corresponding to the western 14th and 15th centuries, are constructed of the most sumptuous materials and in their gravely beautiful lines perfectly express the ritual quality of these highly symbolic poetic dramas. *Nô* masks are among the most skilfully made and possibly are the most beautiful in the world. The popular theatre is the Kabuki, derived from the esoteric ritual drama but far removed from it in spirit and prestige. The Kabuki's costumes are handsome and as remote from the ordinary dress of the audience as its gesturing is

from everyday movement. The Kabuki actor dresses carefully in layers of traditional garments and transforms his natural appearance with wonderfully constructed wigs and with stylized make-up in conventionalized symbols of line and colour. Japanese acting traditions have broken down to some extent under the impact of western theatre and especially western motion pictures. Nevertheless much of tradition remains in the pantomimic dance dramas.

**Java.**—Javanese theatre has preserved its ritual character and the costumes that express so well the symbolic movements of its highly trained dancer actors. This form is said to have derived from the shadow plays that used not men but marionettes in the form of cutouts; it has preserved in its costumes something of the rigidity and strange beauty of these prototypes. Masks play an important part.

**Burma.**—In Burma with its ancient Hindu culture the costumes are sumptuous and reflect almost literally the dress represented on ancient temple sculpture. They are cleverly constructed for their functions in the dance drama.

The theatre costume of the east is primarily theatrical. It may be distinguished by those elements that set theatre costumes apart from ordinary clothes in all parts of the world; these elements include: exaggerations or distortions of the familiar; holdovers from the past that take on symbolic meaning as they become obsolete and exotics deliberately introduced from distant lands or legendary epochs.

### MODERN DESIGN AND CONSTRUCTION

**An Integral Part of the Play.**—Throughout the long history of theatre costuming, designs have been adopted for a variety of reasons: their wearability, their usefulness as identification, their dignity, their symbolic meaning, their magic potency, their flattery of the wearer's ego, their advertisement of the producer's wealth and importance. Modern designers of theatre costumes still have to take into account all these factors—even magic—but the approach is somewhat different. It is now expected of the costume designer as of the scenic artist that he will fully understand the aim of the production as a whole, the meaning of the play and the nature of the characters he is to dress. For this reason he must subordinate his own creative artistry to the demands of the play as it is to be presented. He is only one partner in a co-operative enterprise of author, director, designers and actors.

To express the dramatic idea clearly in terms of costume requires constant vigilance to include only essentials; in other words, the designer must eliminate whatever does not serve to identify a character or interpret him. The designer thinks in terms not of single costumes but of the whole stageful. He subordinates minor characters in order that he may focus attention on the protagonists. With his costumes he helps to compose a scene, balancing colour with colour, line with line, texture with texture. Above all, mindful not only of the characterizations that his costumes are to help but also of what their wearers are called upon to do physically, he designs clothes that can be worn without discomfort or without hampering the actor. On this score, costumes for the dance are the greatest challenge to the designer, who must constantly curb the exuberance of his imagination to leave the dancer free. A dance costume design must satisfy the choreographer, who knows what the performer has to do in it. The dancer's body is his major tool of expression and creates its own design. Too easily is this design obscured by irrelevancies in drapery or ornament. On the other hand, it may be accentuated by colour, flat decoration and texture. The fabric itself, clinging, floating or trailing, contributes materially to the rhythm of the dance. The successful designer of dance costumes has learned the value of simplification. He will not disregard the lesson when he thinks in terms of drama, opera or musical.

The designer for the modern stage must take into account not only the scenery against which his costumes will appear but also the lights under which they will be seen. His knowledge of fabrics must therefore include an acquaintance with the effect of coloured lights on coloured textiles. Because he is aware of the transformations that take place on the lighted stage, he chooses his palette in close co-operation with the scenic artist. This done, a busy de-

signer for the commercial theatre may call upon assistants to sample-shop for him; many prefer to shop for themselves. His costume plates will be accompanied by swatches of the materials selected, including trimmings. He may add enlarged-to-scale drawings of the ornamentation.

**How Costumes Are Made.**—After costumes are designed, the workshop takes over. The commercial theatre is served by costume makers whose shops employ specialists in every branch of construction. The shop is headed by a costumier upon whose understanding and experience depends the successful realization of the artist's design. (In theatres in colleges and civic organizations in many parts of the world the artist himself supervises the execution of his designs.) Costume making calls for many skills besides dressmaking and tailoring—dyeing, for instance. Although the larger yardages may be handed over to a professional dyer, there will be times when a craftsman must work with dye for special effects, such as shading from one value to another, tie-dyeing and ornamenting with stencil, batik or freehand brushwork. There must be wigs—not only hair wigs that require great skill and much time to construct but also others, often not realistic and made from such materials as rayon, horsehair, nylon, raveled rope, string and felt. There must be millinery of all imaginable sorts. There must be footwear, from sandals to boots. Skilled shoemakers specialize in theatrical footwear, but again sometimes even boots are made in the workshop. Armour is not considered beyond the scope of the workshop, for armour appropriate and theatrically truthful can be made from a variety of materials: papier mâché, leather, felt, all of these metallized and possibly augmented with real metal; brass, steel, copper or aluminum in the form of scales, rings, disks or thin strips. Jewelry of every variety is produced from the same sort of materials as well as from balsa wood and cork.

Costumes are often made from fabrics not generally used by dressmakers or tailors, since for theatre costumes the right material may be located in unorthodox places: in the upholstery department, the houseware section, even the hardware store. Costumes have been made successfully from canvas, Osnaburg, felt, leatherette, carpeting, sheet rubber and all the synthetics including plastics. To the imaginative costumier the material that will look right on the actor on stage is the proper material, however unorthodox such a use may seem. Of course the modern costumier has at his command the natural fabrics that his predecessors used—cotton, wool, silk; often he still finds one of them the ideal material. But he also has at his disposal the range of man-made fabrics and stiffeners. Particularly valuable are the nylon nets, especially for use as ruffs and standing collars and tutus.

The construction of a costume starts with the underpinning. Padding of all kinds, corsets and such supports as farthingales, panniers and hoop skirts should be acquired or constructed with extreme care, for on them depends the basic integrity of the exterior. Over such foundations and adequate petticoats a muslin lining is tried on the actor; alterations are made in it to ensure becomingness as well as fit. At this point the cutter and draper take over; upon their sensitivity to the grain of the material depends the ultimate success of the costume. Next it goes to seamstresses, whose sewing must be accurate and above all dependable, because on stage a ripped seam or loose fastening may mean catastrophe. Thus all these craftsmen become inevitably co-creators with the costume designer, who should never forget that his design is not the handsome picture he submitted to the director but the finished garment on the actor upon the stage before an audience.

sance Stage (1938); Virginia More Roediger, *Ceremonial Costumes of the Pueblo Indians* (1941); Lillian Wilson, *The Clothing of the Ancient Romans* (1938).

**COSWAY, RICHARD** (c. 1742–1821), English miniaturist, was born in Devon and baptized in Nov. 1742. Before he was 12 he was sent to London and apprenticed to Thomas Hudson, under whom he learned oil painting. He exhibited at the Royal Academy from 1770 to 1806 and was elected associate in 1770 and full academician in 1771, the rapidity of these elections being the more surprising in that he was principally a portrait miniaturist, then not a very highly regarded art. He used transparent water colours on ivory, allowing the tone of the ivory to shine through, a practice quite different from the solid painting of the 16th- and 17th-century masters.

Vain, superstitious and foppish, he was fortunate in securing the patronage of the prince of Wales, although the rumours connected with the parties held in his house were not to his credit. In 1781 he married Maria Hadfield (c. 1760–1838), who was also a miniaturist and painter in oils. He died at Edgware, Middlesex, on July 21, 1821.

Cosway's miniatures are well represented in London (Victoria and Albert museum, Wallace collection), in the royal collection and at Cambridge. See **MINIATURE PAINTING**.

**COTABATO**, a province of Mindanao Island, Republic of the Philippines. Area 9,181 sq.mi. Pop. (1960) 1,029,119. It has upland margins, and the Liguasan marsh and Lake Buluan are in the central lowland. The area is drained by the Rio Grande de Mindanao. Buluan, near the lake, and Koronadal, near the south coast, are new centres of settlement. Formerly inhabited by Muslim Moros, the province is being settled by Catholic Visayans. The capital is Cotabato (pop. [1960] 37,499), at the mouth of the Rio Grande. It is an important commercial centre and an interisland port shipping rice, maize, abaca and ramie.

(J. E. Sr.)

**COTARELO Y MORI, EMILIO** (1857–1936), Spanish literary scholar, who became secretary of the Academia Española and conducted much of his research on its behalf, was born at Vega de Ribadeo, Asturias, Spain, on May 1, 1857, and died at Madrid on Jan. 27, 1936. His investigations were varied, his method more scientific than that of the better-known Menéndez y Pelayo; his documentary results were monumental. Notable are his researches on dramatic history: on the 18th-century stage and histrionic art; on the prolific dramatist Ramón de la Cruz; on the problematic Tirso de Molina; and on the origins of opera. The most famous of his publications is *Iriarte y su época* (1897), a detailed survey of 18th-century literary society. (I. L. Mc C.)

**CÔTE-D'OR**, a *département* of east central France, formed in 1790 from the northern part of Burgundy (*q.v.*) and bounded north by Aube, northeast by Haute-Marne, east by Haute-Saône and Jura, south by Saône-et-Loire and west by Nièvre and Yonne. Pop. (1962) 387,869. Area 8,765 sq.km. (3,384 sq.mi.).

The limestone plateau of Langres crosses the *département* from northeast to southwest and forms the watershed between drainage to the Seine and that to the Saône. Southwest of Dijon its south-east-facing escarpment is the Côte-d'Or, the crest of which exceeds 2,000 ft. The Langres plateau slopes northwest, as the rocks dip toward the centre of the Paris basin, and in the extreme north of the *département* a groove of well-farmed clay country, known as La Vallée in contradistinction to La Montagne of the Langres plateau, runs northeast-southwest in front of a broken, wooded escarpment of Corallian limestone. The high, exposed Langres plateau, with only thin soils on its porous, stony surface, is extensively wooded and thinly settled. Spurs from the granitic highland of the Morvan extend into the west of the *département*. Between these hills and the backslope of the Côte-d'Or, in the upper basin of the Armançon, the undulating Lias clay country of Auxois provides rich cattle-fattening pastures. The lower alluvial terraces of the Saône plain are richly cultivated, wheat and maize being especially important, but there are

also sandy tracts that carry extensive forests, such as that of Côteaux. Along the foot and lower slopes of the Côte-d'Or is the great wine-producing district of Burgundy, its vineyards comprising the two main groups of Beaune and Nuits. Farther north-east, the continuation of the escarpment in the Dijon district is another important area, though orchards have encroached here upon former vineyards.

The main line of the Sud-Est region railway (formerly the Paris-Lyon-Méditerranée) traverses the *département* on its way from Paris to Dijon and the south, and important trunk roads also converge upon Dijon. The Burgundy canal, connecting the Saône with the Armançon headstream of the Seine, also passes through Dijon, and the Marne-Saône canal crosses the extreme east of the *département*. Dijon (*q.v.*) is the capital of the *département*, the seat of a bishopric, an *académie* (educational division) and a court of appeal. It is a great commercial as well as an administrative and cultural centre and has a variety of important industries, including food preparation and engineering. Little medieval building remains at the famous Cistercian abbey of Cîteaux, home of St. Bernard, but Fontenay is the best preserved of the great Cistercian houses. Montbard has the remains of a castle of the dukes of Burgundy that was later the home of the 18th-century naturalist Buffon. (Ar. E. S.)

**CÔTES-DU-NORD**, a maritime *département* of northwestern France formed in 1790 from the northern part of the old province of Brittany (*q.v.*), is bounded north by the English channel, west by the *département* of Finistère, south by that of Morbihan and east by that of Ille-et-Vilaine. Pop. (1962) 501,923. Area 6,888 sq.km. (2,656 sq.mi.).

Côtes-du-Nord consists of much denuded folds of ancient sedimentary rocks, with extensive intrusions of granite masses. Inland the Landes du Méné, the highest parts of which exceed 1,000 ft., form the watershed between the southward drainage to the Bay of Biscay and the Rance, Arguenon, Gouessant, Gouet and Tréguier rivers, which with other small streams flow north toward the Channel in winding, steep-sided valleys that cut transversely across the grain of the country. The coast is extremely rocky and indented, with discontinuous patches of more level land between the promontories. Market gardening is extensively practised there on smallholdings, advantage being taken of the special mildness of the coastal climate, the availability of seaweed fertilizer and the accessibility of the British market. Onions are an especially important crop around Saint-Brieuc. The interior, humid and windswept and with poor acid soils, is used chiefly for pasture. Some of the formerly extensive tracts of heath remain, though much reduced by modern enclosure. Rye, oats and buckwheat, formerly the chief crops, have tended to make way for pasture as farming has become increasingly specialized upon livestock. Cattle and pigs are important, but there are comparatively few sheep.

Longshore fishing, especially for mackerel, is an important activity of the numerous small ports, and trawlers from Paimpol operate in Icelandic and Newfoundland waters. The picturesque coastal scenery, sheltered coves and quaint fishing villages attract increasing numbers of visitors, and the tourist industry is thriving. In the east of the *département* the Côte d'Émeraude around Dinard (*q.v.*) is especially popular, and the rugged granite coast of Trégorrois in the west also deserves mention. Like other parts of Brittany, Côtes-du-Nord is rich in prehistoric remains and there are many interesting churches. The cathedral at Tréguier and the ruins of the 15th-century castle of Tonquédec, 7 km. (4 mi.) S.E. of Lannion, are noteworthy buildings.

Côtes-du-Nord is divided into the *arrondissements* of Saint-Brieuc, Dinan, Guingamp and Lannion. Saint-Brieuc, the capital, is also the seat of a bishop. The *département* comes under the archbishopric, court of appeal and *académie* (educational division) of Rennes (*q.v.*). (Ar. E. S.)

**COTINGA**, any of a family (Cotingidae) of tropical and subtropical American birds best known for its colourful and bizarrely ornamented forms among the males; the females are generally of drab coloration. The family is very diverse; among the approximately 90 species are birds so small and so plain as to seem to be of another family entirely. They are all alike, however, in having

rather broad bills, slightly hooked at the tips; rounded wings; and short strong legs. The most extraordinary species are those of the tropics, which display a variety of bright-coloured wattles, knobs, crests, and feather ridges. The close resemblance of some cotingas, especially of the genus *Attila*, to the New World flycatchers (*Tyrannidae*) suggests a close relationship to that family.

Cotingas are mainly forest birds of the treetops, which explains why many of them are known only from infrequent sightings and from their strange calls, as remarkable and as diverse as these birds are in appearance. Although chiefly fruit eaters, some cotingas take insects on the wing. They prepare a wide variety of nests—from flimsy open cups to mud-plastered hanging chambers or abandoned tree cavities. Outstanding are the cocks of the rock (*Rupicola* species), Amazonian parrot-sized birds, golden to reddish, with dark wing markings and a head crest that almost conceals the bill. Bellbirds (*Procnias* species), named for their penetrating calls, show erectile or hanging fleshy wattles, notched and twisted feathers, and other unusual adornments, especially around the head. Umbrella birds (*Cephalopterus* species), among the largest of the family—about crow sized—have a curious erectile feathery head crest and an inflatable (during courtship) fleshy, tubular wattle hanging from the throat or chest.

**COTMAN, JOHN SELL** (1782–1842), English watercolourist and etcher, and the greatest member of the Norwich school, was born in Norwich on May 16, 1782, and was sent to London to study about 1798. Through Thomas Monro he met both J. M. W. Turner and Thomas Girtin. From 1800 to 1806 he exhibited watercolours at the Royal Academy, and some of his works of this period, with their grand simplicity and geometrical composition, are now reckoned as among the finest English landscape paintings. In 1807 Cotman left London and returned to Norwich, where he worked as a drawing master and exhibited regularly with the Norwich Society of Artists, of which he was a leading member. In 1812 he moved to Yarmouth and began a long period of work as an archaeological draftsman in collaboration with the antiquary Dawson Turner. He visited Normandy in 1817, 1818, and 1820. In 1823 he returned to Norwich and in 1834 to London, where he died on July 28, 1842. In his last years his style changed completely and he started using rice paste mixed with his water colours to get a richer and more impasted effect, like oil painting. His sons, Miles Edmund (1810–58) and Joseph John (1814–78), were also painters. Cotman is well represented in the Victoria and Albert and British museums, London, and in Norwich.

See S. D. Kitson, *The Life of John Sell Cotman* (1937); V. G. R. Rienacker, *John Sell Cotman* (1953). (P. J. My.)

**COTOPAXI**, a province (formerly called León) in highland Ecuador, bounded west by Los Ríos, north by Pichincha, east by El Oriente and south by Tungurahua and Bolívar. Pop. (1962) 154,971. Area 2,241 sq.mi. On its northeast border is the active volcano of the same name. The chief concentration of people is in the basin of Latacunga, drained by the Río Patate, a headwater of the Pastaza. The capital is Latacunga. The crops include wheat, barley, potatoes, maize, vegetables and fibre plants. Much land is used to pasture dairy cattle, and the higher mountain grasslands are used for sheep. The province is served by the railroad that connects Guayaquil with Quito, and by the Pan-American highway, both of which pass through Latacunga.

(P. E. J.)

**COTOPAXI**, a mountain in the Andes of Ecuador in South America, probably the world's highest active volcano. It is located 30 mi. S. of Quito, at latitude 0° 40' S., and longitude 78° 26' W. It rises to a height 19,347 ft. above sea level. Cotopaxi looms above the Eastern Cordillera of the Andes on which it stands, with an almost perfectly symmetrical cone, interrupted only by one minor cone—the *Cabeza del Inca*, or Inca's Head. It has a long record of violent eruption and the country about its base has many times been devastated by earthquakes or buried in pumice and ash blown out of the crater. The mountain itself is built up of alternating flows of dark-coloured trachytic lava and falls of lighter-coloured ash. Porous ash from this and other Ecuadorean volcanoes covers the basins between the Andean ranges to great depths. The crater at the top is 2,300 ft. in diameter from north

to south, and 1,650 ft. from east to west. Its depth is 1,200 ft.

Much of the time the beautifully symmetrical cone of Cotopaxi is hidden by clouds that are lighted up at night by the fires in the crater. The base of the volcano stands on open paramos, or mountain grassland; but the whole upper part of the mountain is covered with permanent snow. The snow line on the drier western side is about 15,500 ft. above sea level, but on the wetter eastern side it is about 1,000 ft. lower. Sometimes the mountain is crowned by a huge cumulus cloud in which the mountaintop is hidden; at other times the base of the volcano is hidden by a cloud sheet and the top stands majestically against the dark blue of the sky. The prevailing wind at the summit is from the north-west, causing the plume of volcanic smoke to drift toward the southeast.

The first European to attempt an ascent of Cotopaxi was Alexander von Humboldt in 1802. He failed to reach the top and pronounced the mountain unclimbable. Other failures in 1831 and 1858 seemed to confirm this verdict. But in 1872 Wilhelm Reiss succeeded in reaching the top on Nov. 28, and in May of the following year A. Stübel was also successful. Other famous ascents were made by T. Wolf in 1877, M. von Thielmann in 1878, and Edward Whymper in 1880. (P. E. J.)

**COTSWOLDS**, a range of hills in the western midlands of England. The greater part lies in Gloucestershire, but they also extend into Somersetshire, Wiltshire, Oxfordshire, Worcestershire and Warwickshire. The range forms part of the Jurassic escarpments which cross the country from Dorset to north Yorkshire. The northwestern scarp face rises abruptly from the clayey Triassic and Liassic beds flooring the valleys of the lower Severn and the Warwickshire Avon and slopes gradually down to the east. The limestones forming the steeper slopes are mainly of Great Oolite age near Bath, but of Inferior Oolite age behind Cheltenham. The rock is generally of a rich cream colour, in places long quarried as a building stone because it hardens and mellows with exposure. The range extends for 60 mi. from the Bristol Avon to the Chertwell, widening from about 6 mi. in the south to nearly 30 in the north. Heights average from 600 to 700 ft., reaching a maximum at 1,083 ft. in Cleeve Cloud which overlooks Cheltenham. The Thames-Severn watershed is near the western edge except where the Frome tributary of the Severn cuts deep into the hills near Stroud. The region is noted for its picturesque countryside. From the 10th to the 18th century the Cotswolds were famous as open sheep pastures and gave their name to a large long-wooled breed (see SHEEP). The wealth obtained from sales of wool is evident in the buildings of its many villages and small towns, such as Burford, Chipping Campden, Cirencester, Malmesbury and Northleach, and especially in their fine churches. The enclosure of the sheepwalks led to a gradual change to mixed farming; the fields are often divided by dry-stone walls. Some minor cloth manufactures are still carried on; e.g., at Witney and Stroud. In the Cotswolds are many prehistoric long barrows. (T. Hux.)

**COTTA**, the name of a family of German publishers, the most notable of whom is celebrated for his connection with Goethe and other writers of the period.

JOHANN GEORG COTTA (1631–92) was the founder of the publishing house. He settled in Württemberg and in 1659 acquired by marriage the bookseller's business of Philipp Brunn at Tübingen, thereby establishing the J. G. Cotta'sche Buchhandlung. On his death the firm passed to his son Johann Georg (2) and after him to his eldest son Johann Georg (3).

JOHANN FRIEDRICH COTTA (1701–79) was the second son of Johann Georg (2). In 1733 he became professor of philosophy at Tübingen, and subsequently professor of theology at Göttingen (1735) and Tübingen (1739). He was a well-known theological writer in his day.

CHRISTOPH FRIEDRICH COTTA (1730–1807), son of Johann Georg (3), established a printing house to the court at Stuttgart. It was Christoph Friedrich's son, Johann Friedrich, who restored the fortunes of the family firm, then in decline.

JOHANN FRIEDRICH COTTA, FREIHERR VON COTTENDORF (1764–1832), was born at Stuttgart on April 27, 1764. He studied at Tübingen, spent some time in Paris and qualified as a barrister.

However, learning that the family business at Tübingen was to be sold, he took upon himself the task of restoration. At that time he was 23 and totally inexperienced in the business. In 1794 he planned with Schiller the *Horen*, a periodical which, although it only ran until 1797, has a place in the history of German literature. Through Schiller, Cotta met Goethe, and his connection with other literary men increased. He became in time publisher not only to Goethe but also to Herder, Wieland, A. W. Schlegel, Tieck, Jean Paul, Kleist, Hölderlin, Uhland and others. He also published for the brothers Humboldt and for such philosophers as Fichte, Hegel and Schelling. In 1798 he began to publish the *Allgemeine Zeitung*. (Censorship difficulties caused the editorial office of the newspaper to be transferred from Tübingen to Stuttgart, in 1803 to Ulm, in 1810 to Augsburg and in 1882 to Munich. It ceased publication in its traditional form in 1912.) In 1811 the firm moved to Stuttgart, and in 1823 Cotta started a branch in Augsburg and in 1827 one in Munich. By that time he had made his publishing house one of the first in Germany. He developed his political interests, going on several official missions to Paris. He attended the Vienna congress to make, among other commissions, a plea for freedom of the press on behalf of German booksellers. He also had scientific interests. He was a progressive farmer and in 1824 he introduced the first steam printing presses in Bavaria into his Augsburg branch. In 1820 the title of von Cottendorf was conferred on him by Württemberg, and in 1822 he was created hereditary Freiherr by the king of Bavaria. He died in Stuttgart on Dec. 29, 1832.

His son JOHANN GEORG COTTA (4), FREIHERR VON COTTENDORF (1796-1863) extended the firm by buying in 1839 the business of G. J. Göschen in Leipzig and in 1845 that of Vogel in Landshut. In the same year Bible branches were started at Stuttgart and Munich.

Johann Georg (4) was succeeded by his son Karl and by his nephew Hermann Albert von Reischach. They preserved the Stuttgart branch and the *Allgemeine Zeitung* office in Augsburg but the other branches gradually broke away. In 1889 the firm was bought by Adolf and Paul Kröner. The buildings were badly damaged in World War II but the firm was subsequently re-established.

**COTTBUS**, a town of Germany which after partition of the nation following World War II became headquarters of a *Bezirk* (district) of the German Democratic Republic, lies chiefly on the left (western) bank of the Spree river about 110 km. (68 mi.) S.E. of Berlin and about 20 km. (12 mi.) from the Polish border. Pop. (1964) 73,257. Cottbus was founded in the 12th century, becoming part of Brandenburg in 1445 and of the kingdom of Saxony 1807-13. It has 14th- and 15th-century churches and the Spremburg tower is a remnant of the old fortifications. The town is a railway junction and an industrial centre with manufactures of textiles, leather, tobacco, machinery and soap. Cottbus district had a population (1964) of 831,837 and an area of 3,190 sq.mi.; the neighbourhood was one of the last in which the Wendish language survived.

**COTTENHAM, CHARLES CHRISTOPHER PEPYS**, 1ST EARL OF (1781-1851), lord chancellor of Great Britain, whose important contribution to the statute-book was the Judgments act (1838), which amended the law for relieving insolvent debtors, was born in London on April 29, 1781. Descended from John Pepys, of Cottenham, Cambridgeshire, a great-uncle of the diarist Samuel Pepys, he was educated at Harrow and Trinity college, Cambridge, and after being called to the bar by Lincoln's Inn in 1804 and practising at the chancery bar, he became a king's counsel in 1826. In 1831 he entered parliament, and in 1834 became solicitor general and was knighted. Later the same year he was appointed master of the rolls. Next year he was one of the commissioners of the Great Seal, and in Jan. 1836 he became lord chancellor and Baron Cottenham under Lord Melbourne. He lost office with his party in 1841, but in 1846 under Lord John Russell he was again chancellor. In 1850 he retired and was created Viscount Crowhurst and Earl of Cottenham, and on his birthday in 1851 he died at Pietrasanta, near Lucca, Italy.

Although not profoundly learned, he was a good equity lawyer.

He was direct and straightforward, and despite being somewhat rigid and overtenacious of first impressions, and latterly increasingly slow and testy, he was an excellent judge.

See E. Manson, *The Builders of Our Law* (1904); J. B. Atlay, *The Victorian Chancellors* (1906). (R. E. My.)

**COTTI REGNUM** ("Kingdom of Cottius"), a district of ancient Liguria (q.v.), Italy, commanding the important route into Gaul over the pass (6,083 ft.) of Montgenevre. In 58 B.C. Caesar established friendly relations with the king of the district, Donnus, whose son Cottius was confirmed in his position by Augustus. Under Nero, after the death of the last Cottius, the district was annexed, becoming the procuratorial province of Alpes Cottiae. A triumphal arch in honour of Augustus can be seen at the ancient capital Segusio (the modern Susa). (J. B. W.-P.)

**COTTINGTON, FRANCIS COTTINGTON, BARON** (c. 1579-1652), English lord treasurer and ambassador, was a supporter of Roman Catholicism and of Spain during the political struggles preceding the Civil War. He was appointed English agent in Spain from 1609 to 1611. In 1612 he became consul at Seville. Returning to England, he became a clerk of the council in 1613 and in 1616 ambassador to Spain. In 1622 he became Prince Charles's secretary and the next year accompanied Charles and the duke of Buckingham to Madrid. On their return he fell into disgrace as a result of Buckingham's enmity, but after the duke's assassination he regained his position, being made a privy councillor in 1628. Next year he became chancellor of the exchequer and was again sent as ambassador to Spain. He concluded the treaty of peace with that country and in 1631 was created Baron Cottington of Hanworth, Middlesex. Archbishop William Laud's opposition prevented him from becoming lord treasurer in 1635-36, but his prominence in Charles's council, his exactions as master of the court of wards, his Roman Catholic and Spanish leanings and his declaration that for the Scottish War the king might levy money without parliament made him unpopular when the Long parliament met. He gave up the court of wards in 1641 and the chancellorship of the exchequer in 1642. He joined the king in 1643, took part in the proceedings of the Oxford parliament and was made lord treasurer in October. He signed the surrender of Oxford in 1646 and, being excepted from the indemnity, joined Prince Charles at The Hague in 1648. Next year he accompanied Edward Hyde (afterward earl of Clarendon) to Spain to obtain help for the royal cause but, receiving no response, settled there and died at Valladolid on June 19, 1652. (R. B. Wm.)

**COTTOLENGO, SAINT GIUSEPPE** (1786-1842), founder of the Cottolengo charitable institute and of 14 religious congregations, was born at Bra near Turin, Italy, on May 3, 1786. He was a canon in Turin when in 1827 he was summoned to a woman dying in squalor for want of a hospital to receive her. This painful experience began an extensive and successful series of charitable enterprises. He first hired two rooms to receive the sick, but this venture soon grew into a hospital situated at Valdocco, then on the outskirts of Turin, called the Little House (Piccola Casa) of Divine Providence. He founded the Brothers and Sisters of St. Vincent de Paul to nurse in the hospital, the Sisters of Thais to care for a refuge for penitent women, and a congregation of priests called after the Trinity to minister to homes he established for epileptics, deaf and dumb, orphans, the aged, the mad, etc. In all he founded 14 congregations, both active and contemplative, all affiliated to the Piccola Casa and assisting in its activities. For Cottolengo the active and contemplative lives were interwoven, the latter being the soul of the former. His achievement was based on prayer; he kept no accounts and invested no funds but never ran short of the means for continuing his work. He died on April 30, 1842, at Chieri, near Turin, and was canonized in 1934. His feast day is April 29.

See H. L. Hughes, *St. Joseph Cottolengo* (1934), and the biography by P. P. Gastaldi, 2 vol. (1892). (E. I. W.)

**COTTON, SIR ARTHUR THOMAS** (1803-1899), English engineer, who was responsible for much irrigation work in India, was born on May 15, 1803. He entered the Madras engineers in 1820, served in the first Burmese war (1824-26), and began his life work on the irrigation works of southern India in

1828. He constructed works on the Cauvery, Coleroon, Godavari and Krishna rivers, making anicuts (dams) on the Coleroon (1836) for the irrigation of the Tanjore, Trichinopoly (now Tiruchirapalli) and South Arcot districts, and on the Godavari (1847-52) for the irrigation of the Godavari district. He also projected the anicut on the Kistna. Before the beginning of his work Tanjore and the adjoining districts were threatened with ruin from lack of water; on its completion they became the richest part of Madras, and Tanjore returned the largest revenue of any district in India. Cotton was the founder of the school of Indian hydraulic engineering. He was knighted in 1861 and retired from government service in 1862. He died at Dorking, Surrey, on July 14, 1899.

See Lady Hope, *General Sir Arthur Cotton* (1900). (A. McD.)

**COTTON, CHARLES** (1630-1687), English poet, man of letters and country squire, chiefly remembered for his share in Izaak Walton's *Compleat Angler*, was born on April 28, 1630, at Beresford, Staffordshire, where he lived all his life. His father, also Charles Cotton, was the friend of Ben Jonson, John Donne, Sir Henry Wotton, John Fletcher, Robert Herrick, Sir William Davenant, Richard Lovelace and Izaak Walton. His mother was daughter to the Lady Stanhope for whom Michael Drayton wrote an elegy. Cotton married his cousin, Isabella Hutchinson, half sister of the Puritan colonel John Hutchinson; she died in 1669 and in 1675 he married the dowager countess of Ardglass. He died during a visit to London and was buried in St. James's church, Piccadilly, on Feb. 16, 1687.

Cotton's father had an excellent library and to this, rather than to a visit to France in 1655, he owed his knowledge of French literature. He made a number of translations, including, in 1685, the often reprinted *Essays of Michel de Montaigne* (which is much closer to the original than Giovanni Florio's more famous version), Corneille's *Horace* (1671) and several historical and philosophical works. He followed French fashion also in *Scarronides* (1664, 1665) a coarse burlesque of the *Aeneid*, books I and IV, and in the *Burlesque upon Burlesque . . . being some of Lucian's Dialogue newly put into English Fustian* (1675).

Cotton described himself as "an old-fashioned country squire," meaning one who played his full part in the life of his county, as farmer, sportsman, magistrate and host. From this life he drew the inspiration for all his original writings: *The Compleat Gamester* (1674), *The Planter's Manual* (1675) and the second part, on fly-fishing, which he added, at Walton's suggestion, to the 5th edition of *The Compleat Angler* (1676). (For their pleasure in 1675 Cotton built the fishing house beside the river Dove, with their initials twisted together in monogram above the door.) *The Wonders of the Peak* (1681), a long topographical poem, popular throughout the 18th century, and his other poetry, published in the posthumous and unauthorized *Poems on Several Occasions* (1689), reflect his enjoyment of life.

Although Cotton's fame rests chiefly on his connection with *The Compleat Angler*, the qualities which make it memorable—his delighted observation of the country scene, his friendly charm of manner, the vigour and purity of his style—are all to be found in his poetry, which was much admired by Wordsworth, Coleridge and Lamb.

See John Buxton (ed.), *Poems of Charles Cotton* (1958), a selection which corrects the faulty text of 1689 from a contemporary manuscript. (E. J. M. Bv.)

**COTTON, GEORGE EDWARD LYNCH** (1813-1866), English bishop of Calcutta and, earlier, a distinguished schoolmaster, was born at Chester on Oct. 29, 1813. He was educated at Westminster school and at Trinity college, Cambridge. He became an assistant master at Rugby, where he worked devotedly for 15 years, inspired by the headmaster, Thomas Arnold, and heartily entering into his plans and methods. Cotton is the "model young master" who intervenes at the end of part one of Thomas Hughes's *Tom Brown's Schooldays* (1867). Cotton became master of Marlborough college in 1852, and in his six years of rule raised it to a high position. In 1858 he became bishop of Calcutta, where he established schools for British and Eurasian children, did much to improve the position of the chaplains and was unwearied in mis-

sionary visitation. On Oct. 6, 1866, he was drowned at Kushtia on the Ganges. A memoir of Cotton, edited by his widow, was published in 1871.

**COTTON, JOHN** (1585-1652), English-American Puritan minister, sometimes called the "patriarch of New England," was born in Derby, Eng., on Dec. 4, 1585. He was educated at Trinity college, Cambridge, and became a fellow of Emmanuel college, Cambridge, then a stronghold of Puritanism. In June 1612 he became vicar of the parish church of St. Botolph in Boston, Lincolnshire, where he remained for 21 years. Becoming more and more a Puritan in spirit, he ceased, about 1615, to observe certain ceremonies prescribed by the legally authorized ritual, and in 1632 action was begun against him in the high commission court. He thereupon escaped, disguised, to London, lay in concealment for several months, and eluding the watch set for him at the various English ports, in July 1633 emigrated to the colony of Massachusetts Bay, arriving at Boston early in September. On Oct. 10 he was chosen "teacher" of the First Church of Boston, of which John Wilson (1588-1667) was pastor and there he remained until his death on Dec. 23, 1652. In the newer as in the older Boston his popularity was almost unbounded, and his influence, both in ecclesiastical and in civil affairs, was probably greater than that of any other minister in theocratic New England.

He was a man of great learning and was a prolific writer. His writings include: *The Keyes to the Kingdom of Heaven and the Power thereof* (1644), *The Way of the Churches of Christ in New England* (1645), and *The Way of Congregational Churches Cleared* (1648), these works constituting an invaluable exposition of New England Congregationalism; and *Milk for Babes, Drawn out of the Breasts of Both Testaments, Chiefly for the Spirituall Nourishment of Boston Babes in either England, but may be of like Use for any Children* (1646), widely used for many years, in New England, for the religious instruction of children.

For Cotton's part in the so-called Antinomian controversy, see HUTCHINSON, ANNE.

See the quaint sketch by Cotton Mather, John Cotton's grandson, in *Magnalia* (1702), and a sketch by Cotton's contemporary and friend, Rev. Samuel Whiting, printed in Alexander Young's *Chronicles of the First Planters of the Colony of Massachusetts Bay from 1623 to 1636* (1846); also A. W. McClure's *The Life of John Cotton* (1846) a chapter in Arthur B. Ellis's *History of the First Church in Boston* (1881), and a chapter in Williston Walker's *Ten New England Leaders* (1901). (W. W.)

**COTTON, SIR ROBERT BRUCE, BART.** (1571-1631) English antiquary, the founder of the Cottonian library, was born at Denton, Huntingdonshire, on Jan. 22, 1571. He was a descendant, as he delighted to boast, of Robert Bruce. He was educated at Westminster school under William Camden (q.v.), the antiquary and at Jesus college, Cambridge, where he graduated in 1585. He took a house near Old Palace yard, Westminster, and there began to assemble a collection of manuscripts, books and coins, which he supplemented steadily throughout his life. It became a meeting-place for scholars, who were allowed to use the library freely. In 1614 Arthur Agarde (q.v.) left Cotton his papers, and Camden's manuscripts came to him on Camden's death in 1623. His connection with Camden had been renewed when he joined (c. 1590) the Society of Antiquaries: in 1600 they toured the north of England in search of Pictish and Roman monuments and inscriptions. Cotton assisted in the preparation of the 5th edition of Camden's *Britannia* and was regarded as the compiler of his *History of Elizabeth*. He certainly revised it after Camden's death and had probably supervised it, especially with regard to its treatment of Mary, Queen of Scots. He also helped John Speed to compile his *History of England* (1611).

Cotton's pride in his Scottish ancestry attracted the favour of James I, and he was knighted on the king's accession. In 1608 he wrote a *Memorial on Abuses in the Navy*, and attended the privy council at which the matter was discussed. In 1611 he presented to the king a historical *Inquiry into the Crown Revenues*, in which he supported the creation of the order of baronets as a means of raising money. In the same year he himself received the title.

After this, however, Cotton's favour at court began to decline. His acquisition of so many public documents had aroused misgivings, and in 1615 he was involved in the disgrace of his patron, the earl of Somerset (see SOMERSET, ROBERT CARR), and was arrested. He confessed to having acted as intermediary between Somerset and the Spanish ambassador, and to having altered dates in correspondence to substantiate Somerset's plea of innocence of the murder of Sir Thomas Overbury. Cotton received no formal trial, and was pardoned eight months later, but he never regained his standing at court. Moreover, his antiquarian studies caused him increasingly to lend the weight of his learning to the opponents of Stuart methods of taxation. In the *Inquiry into the Crown Revenues* he had argued that tonnage and poundage should be levied in wartime only, and the circulation in the house of commons of his notes during the debate on supply in 1625 materially contributed to the decision to grant Charles I that tax for one year only. In 1626 he successfully protested on behalf of the London merchants against a proposal to debase the coinage. His *The Reign of Henry III* was published in 1627 in the face of a government threat to prosecute the printers, and in 1628 the opposition leaders, Sir John Eliot, John Pym and Sir Simonds D'Ewes, used his house as their headquarters. Cotton himself had entered parliament in 1601 as member for Newtown; in 1604 he sat for Huntingdon; in 1624 for Old Sarum; in 1625 for Thetford; and in 1628 for Castle Rising, Norfolk.

Finally, the publication of his political tract, entitled *The Danger wherein the Kingdome now standeth and the Remedy* (1628), and the circulation of another, a *Proposition to Bridle Parliament*, the original of which was found in Cotton's library, caused his imprisonment in 1629 and the sealing up of his library. His trial fortunately coincided with the birth of the future Charles II and he was released in honour of the event, but his library was not restored and his zest for life was destroyed. He died, probably in London, on May 6, 1631. His son, Sir Thomas (1594-1662), regained possession of the library and added considerably to it. Sir John, the 4th baronet, presented it to the nation in 1700. It was moved from Cotton house, first to Essex house in the Strand and then to Ashburnham house, Westminster, where in 1731 it was severely damaged by fire. In 1753, when the British museum was founded, it formed the basis of the manuscript collection, and many of the partially burned manuscripts were restored. In the old library at Cotton house, the books and manuscripts had been kept in 14 tall cupboards, on 12 of which stood busts of the Roman emperors, with busts of Cleopatra and Faustina on the remaining two, and catalogues of the library (1696, 1732 and 1802) continued to group manuscripts under the names of the emperors in whose cupboard they were originally kept.

See *Cottoni Posthuma*, collected by J. Howell (1651; ed. by E. Goldsmid, 1884-88); E. Edwards, *Libraries and Founders of Libraries* (1865).

**COTTON**, while supplying a dominant supply of the world's fibre needs, also provides human food and livestock feed. Extensive use of the seed and of the products derived from it is a recent development; the use of the fibre, a mass of unicellular hairs which grow attached to the seed on all types of cotton plants, has been traced as far back as 3000 B.C. through spun cotton yarns found in the ruins of Mohenjo-Daro, a city in the Indus valley. Cotton was mentioned in a Hindu Rigveda hymn 15 centuries before Christ and Herodotus (c. 450 B.C.) tells how the patient hands of women of India plucked lint from seed, carded it and spun yarn for weaving on their crude hand looms. It was grown and spun by the Egyptians, probably in A.D. 600-700. It was the subject of legend and myth during the middle ages, and it was for an additional supply of the fibre that many of the great explorations of the 15th and 16th centuries were undertaken. Cotton has been found in prehistoric pueblo ruins in Arizona, and cotton grave cloths from pre-Inca Peru are still in existence. The spinning of cotton for nets and fishing lines apparently antedated weaving of cloth in Peru and the Caribbean, but when Christopher Columbus landed in the West Indies in 1492 the natives brought skeins of cotton yarn to his ship for barter; Yucatán natives presented cotton garments to Hernán Cortés, and Mexicans were clad in cot-

BY COURTESY OF U.S. DEPARTMENT OF AGRICULTURE

FIG. 1.—LONGITUDINAL SECTION OF COTTON FIBRES: (A), (B), (C) COARSE FIBRES; (D), (E), (F) FINE FIBRES

ton when Cortés established Veracruz. When Vasco da Gama sailed around the African continent to Calicut (Kozhikode) in 1498 he found that, centuries before, Arab traders had taught the natives of Africa to cultivate and spin cotton. From Calicut he brought back to Lisbon *pinhados*, or calicoes.

An examination of one of the earliest-known fragments of cotton textiles reveals an analogous persistence of fibre structure. Breeding has produced longer, finer and stronger cotton, but the fibres from bits of cloth and yarn found in the Indus valley, like the fibres in today's cottons, are flattened, twisted tubes, the walls of which are composed of fibrils of cellulose built up in a number of concentric layers; the textile character known to scientists and the trade as cottonlike is the result of this persistent fibrous structure. The length of a single cotton fibre is from 1,000 to 3,000 times its diameter. The various species of cotton govern the diameter and number of twists the respective fibres have—the more twists, the better the spinning qualities. The spirality of a cotton fibre distinguishes it from all other fibres and gives it elasticity and superior value for spinning. No other natural fibre has this feature.

Despite the increase in production of man-made fibres, cotton continues to be one of the most important of the world's money crops. It is a tropical plant, adapted to temperate zones, thriving best with high temperatures, considerable sunshine, abundant but not excessive moisture and high soil fertility. More than 60 countries within the zone of latitude 47° N. and 35° S. produce cotton for commercial purposes. A trend toward increased cotton production was in evidence in all cotton-producing countries, especially following World War II, when world production reached approximately 40,000,000 bales, compared with a pre-World War II average of 31,600,000 bales. World cotton production was about five times that of both wool and rayon.

In the years following 1940 remarkable advances were made in agronomy. Increased production of desirable-quality cottons and per-acre profit to the farmer became dual dominating factors in the raw-cotton industry. New varieties and strains of cotton were developed to meet the demands of agricultural mechanization, to respond to chemical controls in cultivation and to resist diseases.

## BOTANY

The development of an engineering approach to the design and utilization of textile fibres resulted in a new evaluation of the botanical study of cotton, placing emphasis upon the selection of varieties which will maintain the economic potentials and market stability of the world's most important nonfood agricultural commodity.

**Taxonomy.**—Wild and cultivated species of cotton have been placed in the genus *Gossypium*. Authorities have disagreed on the family and tribe but have agreed in placing the genus in the order Malvales. The seeds of all species of *Gossypium* produce hairs, and the seeds are produced inside capsules (bolls). Four species have been cultivated for the production of lint. *G. herbaceum* and *G. arboreum*, commonly known as Asiatic species, have a haploid chromosome number of 13 and produce short ( $\frac{1}{8}$  to  $\frac{1}{2}$  in.)

coarse lint. *G. hirsutum* is commonly known as American upland cotton. It has a haploid chromosome number of 26 and produces lint of intermediate length ( $\frac{1}{8}$  to  $1\frac{1}{4}$  in.) and coarseness. *G. barbadense* has a haploid chromosome number of 26 and includes types commonly known as Sea Island, Egyptian, American-Egyptian and Peruvian Tanguis. These commercial types, except for Peruvian Tanguis, produce extra long staple ( $1\frac{7}{8}$  to  $2\frac{1}{2}$  in.) which is very fine. Most commercial cotton of the above types falls within the lengths indicated; longer and shorter extremes exist in each type. Botanical varieties of both *G. hirsutum* and *G. barbadense* that occur both in the wild and cultivated state have been described.

Wild species include one with 26 chromosome pairs, *G. tomentosum*, and approximately 20 with 13 chromosome pairs. These latter so-called diploid species occur in the subcontinent of India, Australia, Africa and Arabia and in the Americas from Arizona to Peru. Botanists and geneticists have accumulated evidence indicating that the cultivated tetraploid species (those with 26 chromosome pairs) arose from a hybrid of an Asiatic species or a fairly close relative and a wild American species.

**Fibre.**—Cotton fibres are single plant cells which develop as elongations of the outer layer of cells of the cotton seed. Each fibre consists of an outer or primary cell wall and an inner layer of cellulose comprising the secondary wall. Microscopic examination of the cross section of a fibre reveals the existence of daily growth rings which form a series of concentric circles. During development the inside of each fibre (lumen) contains the living protoplasm of the cell. When mature and exposed to the air, the fibre dries, and the drying is accompanied by flattening and twisting. This process is emphasized because the convolutions in the fibre make it easily spinnable. All cultivated species of cotton are distinguished from wild species by their convoluted lint (seed hairs).

Seed fuzz begins to develop from epidermal cells during the period from 5 to 11 days after opening of the cotton flower, in contrast to the lint development which is initiated on the day of flowering. Commercial types of upland cotton have relatively uniform fuzz over the entire seed; Sea Island, Egyptian and Tanguis have only a portion of the seed covered with fuzz. Seed fuzz from upland cotton is a by-product of the oil-milling industry known as linters and is used primarily as a source of cellulose. (See also COTTONSEED.)

While all lint has in common the convoluted characteristic important to spinning, wide ranges exist in length, coarseness and strength. Differences in these properties exist within the produce of a single variety, and species and varieties within species are quite different in mean values for these properties. In addition to inherent differences, the influence of environmental conditions under which the crop is grown is important. Specialized instruments have been developed for measuring specific properties, including an electronic device for scanning a sample of lint and recording graphically the frequency of fibres of various lengths; strength testers that measure the tensile strength of a flat bundle of fibres, which is reported as strength in relation to the actual weight of the fibres in the sample; and air-flow instruments that estimate relative fineness and coarseness of fibres in a sample by relating rate of flow of air to specific surface of fibres in the sample. Performance of each of these instruments has been related to results obtained by more tedious laboratory methods, and the combined lint properties have been related to the performance of individual lots of cotton in the manufacturing process. Thickness

of the secondary wall of individual fibres is related to measurements of relative fineness, and modifications of the air-flow instruments have been developed to estimate this relative thickness. Unusually thin walls in a given type of cotton often result from adverse environmental conditions, and such thin-walled fibres are called immature. Other immaturity tests include microscopic examination and differential dye tests.

## CULTURE

Most of the cotton produced in the world has been produced by comparatively primitive methods. Into the second half of the 20th century most cotton-producing areas still relied upon animal power for preparing the soil, and the crop was planted, cultivated and harvested by hand. In the United States, which became a major producer of cotton after the invention of the Whitney-Holmes saw-type gin in 1796, mechanization of cotton production lagged behind mechanization in the production of corn, wheat and other crops. The use of tractor power for cultivation developed in the 1920s but did not spread until the 1930s, when additional implements were developed for seed-bed preparation and cultivation. Mechanical pickers and strippers for harvesting the crop had been developed for commercial use by the 1940s, but by 1949 only 6% of the U.S. crop was mechanically harvested; during the 1950s the percentage increased to about 30% but by 1958, in southwestern United States, the most mechanized cotton-producing area in the world, some hand labour was still utilized in weeding and less than  $\frac{1}{4}$  of the crop was harvested mechanically. The degree of mechanization became progressively less from west to east in the cotton belt of the United States, partly as a result of farm size, field size, slope and competition for labour. In areas of Mexico contiguous to the United States the degree of mechanization approached that in the U.S. more closely than in other cotton-producing areas of the world.

See also FARM MACHINERY; HARVESTING MACHINERY: Mechanical Cotton Harvesters.

## GINNING

The earliest record of a mechanical device for separating lint from seed comes from India, which is the country in which utilization of cotton is believed to have developed first. The primitive "churcka" gin consisted of two rollers through which lint could pass but seed could not. From this hand-operated model, power-driven roller gins were developed which continue in use for ginning extra-long staple Sea Island and Egyptian types as well as shorter staple types in India and China, all of which are smooth seeded or sparsely fuzzy. While naked seed occurs as a genetic aberrant in the medium-staple American-upland type, most upland varieties have the dense coat of short fuzz known as linters, and in this type the longer lint hairs are attached more securely to the seed coat.

Hand separation of lint and seed was replaced rapidly by use of saw-type gins in the United States after the inventions of Eli Whitney in 1794 and of Hogden Holmes in 1796. Whitney's gin was improved upon by Holmes who substituted toothed saws for the hooked cylinder and flat metal ribs for the slotted bar used by Whitney. The saws, metal ribs and doffing brush in these early models persist in modern gins, with no basic change in ginning principle having been made, although some modern gins substitute an air blast for the doffing brushes.

Additional gin machinery has been developed to keep pace with changes in harvesting practices which have resulted in a trend from careful hand picking to rougher hand and machine harvesting. These developments include seed-cotton driers, seed-cotton clean-

FIG. 2.—STAGES IN THE DEVELOPMENT OF A COTTON BOLL

ers, burr extractors, green-boll traps and magnetic devices for removing metal. Lint cleaners, designed to remove trash from lint after it had been removed from the seed, were added to modern gins in the late 1940s and 1950s. Improvement in grade, which resulted in a higher price for the lint, was, in some cases, offset by the loss in weight. Gin installations include presses for baling the lint and equipment for moving the seed away from the gin stands. While some of the seed is saved for planting purposes, most of it moves directly to an oil mill for processing. Because whole cottonseed is somewhat toxic when ingested, its utilization commercially had to await the development of oil-extracting equipment, and not all countries producing cotton fully utilize the seed produced (see also FEEDS, ANIMAL).

### PESTS AND DISEASES

**Insect Pests.**—More than 500 species of insects attack cotton, among them being some of the most destructive known to agriculture. With its lush, succulent foliage, large flowers all with nectaries and its extended fruiting period, cotton is an excellent host for many insects. Included in the insects visiting cotton are those with beneficial effects and some with apparently neutral effects on the plant, in addition to the harmful species. A few of the most harmful are the boll weevil, pink bollworm, bollworm, cotton leafworm, cotton aphid, cotton fleahopper, rapid plant bug, conchuela, southern green stink bug, spider mites (red spiders), grasshoppers, thrips and tarnished plant bugs.

The earliest cotton production, utilizing perennials, was ideal for the development of insect populations. The development and use of annual types made possible some insect control through timing of planting and other cultural methods, including sanitation measures such as clean culture and disposal of crop residues at the end of the season. Such methods continue to be important, and modification of varieties by breeding has provided means of escaping most serious damage by insects in some cases and has provided degrees of resistance in others. Chemical control, research on which was started in the early 1900s, has become of great importance. Losses caused by insects have been high in all cotton-producing countries, the annual loss in the United States averaging more than \$243,000,000 since 1929, with an all-time high of over \$900,000,000 in 1950. To the losses caused by insects must be added the cost of control measures, and these have been estimated at \$58,000,000 to \$95,000,000 annually in the U.S.

The pink bollworm (*Pectinophora gossypiella*), first reported in India in 1842, has become generally established in eight of the nine countries that produce nine-tenths of the world's cotton. It has caused an average annual loss of 15% to 25% in India and Egypt; in China it has caused more damage than all other cotton insects together. Losses in Russia have been severe, and in Brazil the average annual loss is 20% to 25%. The pink bollworm appeared in Mexico in 1911 and by 1960 had spread throughout a six-state area in the United States. Control has been attempted through heating or fumigating of cottonseed, burning of gin trash, rolling lint to crush larvae and enforcing destruction of crop residues by specified dates at the end of the season to destroy insects and food supply. Strict quarantines have been enforced on the movement of untreated cotton to help prevent spread of the insect. In a few relatively small areas where sufficiently strict control has been possible the pink bollworm has been eradicated. (See also PLANT QUARANTINE.)

The boll weevil (*Anthonomus grandis*) is believed to be a native of Mexico or Central America and it is restricted to the northern hemisphere of the Americas. Another closely related species occurs in South America. After entering the United States in 1892 and spreading throughout the cotton belt by 1922, the boll weevil became the most serious cotton insect pest. Natural control factors—including about 60% mortality in hibernating weevils, death of emerging adults before cotton produces squares in which eggs may be deposited, and deterrents to rapid multiplication such as heat, dry weather, insect parasites and predators, and birds—make it possible to produce cotton when the weevil is present. Cultural methods of control for the weevil include preparation of a good seedbed, early planting, a relatively early variety, soil improve-

ment and fertilization, proper cultivation, cleanup of favourable hibernation quarters and early destruction of cotton stalks. Direct control by poisoning adult weevils is used when the population of weevils in the field is high enough to warrant it. Continued applications at intervals of four to five days are required because the immature stages of the weevil develop inside the flower buds and young bolls where poison does not affect them, and the continued growth of the plant and chemical breakdown and disappearance of poison from the older parts of the plants prevent a lasting killing effect. Calcium arsenate was used as the sole weevil poison from discovery of its effectiveness in 1916 until about 1948, when organic insecticides became available. Chlorinated hydrocarbons and organic phosphates were used extensively during the 1950s, and late in that decade the appearance of weevils resistant to the chlorinated hydrocarbons were recorded. Certain of the chemicals available effectively controlled other cotton insects and chemical control spread to many cotton-growing areas of the world. (See also BOLL WEEVIL.)

Another major insect is the bollworm (*Heliothis zea*). Unlike the pink bollworm, which has a limited host range, and the boll weevil, which attacks only cotton, the bollworm feeds on many wild and cultivated plants including corn (maize), grain sorghums, tomatoes, peas, alfalfa, lespedeza, beans, soybeans, flax and peanuts. In many areas it moves to cotton from corn, on which it is known as the corn-ear worm. Natural enemies sometimes prevent bollworm infestation, but when bollworms appear the application of insecticides is the best means of control. Poison must be applied when the worms are small, for after they enter the bolls poison will not reach them.

Insects which feed on the leaves and buds, including the cotton leafworm, which is a chewing insect, and the sucking insects including fleahoppers, leafhoppers and aphids, do considerable damage to cotton crops throughout the world. Damage caused by such insects is often difficult to assess because it is not always spectacular, and when sap-sucking insects attack they often cause shedding of very young buds, too small to attract attention. Chemical control is an important adjunct to natural factors affecting the insects. In Africa and Asia damage caused by leafhoppers has been reduced through incorporation of plant hairiness in the commercial varieties. In some areas of Africa the tarnished plant bug is the most serious insect pest.

A stalk borer called broca is a serious pest in parts of South America. The larva enters the stalk at the soil surface as a rule, and it can be controlled either by application of chemicals to the soil surface or seed treatment with systemic insecticides.

**Diseases.**—Cotton is subject to attack by pathogenic fungi, bacteria and virus, and damage caused by nematodes and physiological disturbances are usually called diseases. Descriptions of many of the diseases were published in 1892, although the occurrence of virus diseases was not noted until the late 1950s. Losses caused by disease have been estimated as high as 50% in some countries of Africa and in Brazil. In India losses have ranged from 7% to 20%, and in the United States annual losses as high as 15% have been reported.

A complex of disease organisms attacking young seedlings, with the predominant organism differing with locality and conditions within localities, is probably the most widespread disease problem. In many cotton areas seeds are treated with chemicals before planting to reduce disease injury to seedlings. The second most widespread problem is a bacterial disease known either as angular leaf spot or black arm, depending upon which symptom of the disease is predominant in the area. In African countries outside of Egypt this is considered the most serious disease, and considerable progress in breeding resistant varieties has been made. It is not a problem in areas of little or no summer rainfall like Egypt and California where cotton production depends on irrigation. Considerable attention has been given to the development of resistant varieties in some areas of the United States.

Fungus diseases attacking growing plants include fusarium and verticillium wilt and Texas root rot. The latter is limited in distribution by soil type, soil reaction and climate primarily to areas of Mexico, Texas, New Mexico and Arizona. Fusarium wilt is

somewhat restricted to sandy and mixed soils, usually occurring in combination with nematodes in areas with 40 or more inches of annual rainfall. It is an important disease in the United States and is the major disease in Egypt. Soil fumigation is effective in control, but the development of resistant varieties has provided the best means of control. Verticillium wilt is most serious in heavy soils and is more serious with heavy irrigation and high levels of soil nitrogen. Losses in the irrigated southwest of the United States were reduced through the use of tolerant varieties and modified cultural practices. It has been reported in other countries in both the northern and southern hemispheres, and its distribution may be in doubt because of the similarity of its symptoms to those of fusarium wilt. Both cause chlorosis, or blanching of the green parts, leaf drop and ultimate death of the plant.

Boll rots can cause severe damage to the crop. The bacterium causing angular leaf spot also attacks green bolls, and the lesions formed permit the entry of secondary invaders. Partially open and open bolls are attacked by several fungi, both pathogenic and saprophytic, and the lush foliage of the plant provides ideal conditions for the development of such organisms on the lower bolls, particularly in areas of high humidity at the time the crop matures.

Nematodes are widespread, and the damage they cause both in combination with fusarium wilt and alone has most likely been underestimated. Soil fumigation and varietal resistance both provide control.

### PRODUCTION AND MARKETING

World production statistics as compiled in the United States are for actual bales of U.S. cotton (these bales average 490 lb. net weight) and for equivalent bales of 478 lb. net for non-U.S. cotton. The approximate world crop of 48,000,000 bales is the combined output of over 60 countries including the United States (15,000,000 bales), Brazil (1,800,000), China and Manchuria (7,500,000), Egypt (2,000,000), India (4,500,000), Pakistan (1,300,000), the U.S.S.R. (7,000,000) and Mexico (2,000,000).

**World Production.**—The United States, the world's largest producer, accounted for 60% of the total in 1929-30, 41% in 1939-40 and 50% in 1949-50, but by the mid-1950s produced only about 39% of the total. In 1933 acreage control and price supports were established in the United States in order to aid farmers during a period of economic distress. Continued control and price support, except during World War II and certain years of predicted short supply, have been a factor in a shift in world production. Price supports in the U.S. have encouraged the production of cotton by other countries by enabling them to compete in the world market and have also encouraged the production of synthetics, which have been able to compete with cotton at the level of supported prices.

Among the countries which consume a high percentage of the cotton they produce are the U.S., the U.S.S.R., China, Korea, India, Brazil and Argentina. Among those exporting most of their production are Egypt, Turkey, Mexico, Peru, Republic of Sudan, Uganda and Republic of the (former Belgian) Congo. Chief among the importers of cotton are Japan and countries of the European Common Market.

Quality of cotton is commonly measured in terms of length and coarseness or fineness of the lint. Other factors, including amount of trash in the bale and discoloration of the lint, also determine price (see *Classing and Marketing*, below) but may or may not be directly related to the spinning quality of the cotton. Roughly 70% to 75% of world production is in the range of length from  $\frac{7}{8}$  to  $1\frac{1}{8}$  in. About 12% to 15% is in the range from  $\frac{3}{8}$  to  $\frac{7}{8}$  in. About 9% ranges from  $1\frac{1}{8}$  to  $1\frac{1}{2}$  in. and 1% is  $1\frac{1}{2}$  in. and longer.

About 95% of the cotton produced in the United States is  $\frac{7}{8}$  to  $1\frac{1}{8}$  in., the remainder consisting of long staple upland and American-Egyptian and a very small percentage below  $\frac{7}{8}$  in. produced in areas with adverse seasonal conditions. Roughly 5% of the Indian crop is 1 to  $1\frac{1}{8}$  in., 30% to 35% is  $\frac{7}{8}$  to  $\frac{3}{4}$  in. and 60% to 65% less than  $\frac{7}{8}$  in. There is a continuing trend in India to produce more of the longer (1 in.) cotton in place of the shorter types by replacing the Asiatic species with adapted varieties of American upland. Practically all Egyptian cotton is  $1\frac{1}{8}$  in. or

longer, with the longer group coming from adapted *G. barbadense* varieties producing lint up to  $1\frac{1}{8}$  in. Brazil produces 95%  $\frac{3}{8}$  to 1 in. cotton and about 5%  $1\frac{1}{8}$  in. China produces short cotton primarily,  $\frac{7}{8}$  in. and shorter. Since much of this is used in the home, it has little influence on cotton in world trade. Russian cotton is mostly  $\frac{7}{8}$  to  $1\frac{1}{8}$  in. Increased production in Russia has therefore been in direct competition with many other countries, even though Russia exports only negligible amounts. Long staple types are imported by Russia, primarily from Egypt.

Of the remaining cotton-producing countries, most produce lengths in the range  $\frac{7}{8}$  to  $1\frac{1}{8}$  in. Peru is a notable exception, where 85% is about  $1\frac{3}{8}$  in., 7% is  $1\frac{1}{2}$  in. and the remainder is  $1\frac{1}{8}$  to  $1\frac{3}{8}$  in.

**Classing and Marketing.**—The market value of cotton is determined by length of the fibre, colour, preparation and foreign-matter content. These characteristics are used in determining grade and staple; additional measurements on fibre fineness, strength and maturity came into use on an extensive basis during the 1950s in some phases of marketing. Classing systems vary throughout the cotton-producing and -consuming areas of the world; a brief description of the United States system will serve as an example. All bales are sampled individually, approximately three to six ounces of lint from each of two sides of the bale, at the gin. Unless sold directly to a mill, the bales will be sampled again after periods of storage or when the bales are offered to a subsequent buyer.

Grade standards in use in the U.S. for white cotton, ranged from best to poorest, are: good middling, strict middling, middling, strict low middling, low middling, strict good ordinary and good ordinary. Coloured cottons include spotted, tinged, yellow-stained and gray, and within each of these colours no grades of ordinary exist. Cotton not fitting the description of any of the established grades is called below grade. The grade of each sample is determined by matching it with a sample in the official box of standard samples as prepared and distributed by the U.S. department of agriculture. The above standards apply to upland cotton up to  $1\frac{1}{8}$  in. in length and, with special consideration given to preparation (ropy, matted or otherwise undesirable condition of the lint in the bale), to upland over  $1\frac{1}{8}$  in. Sea Island is classed in grades one to six, with half grades for description, and American-Egyptian cotton in grades one to nine.

Classing is done by men employed by the department of agriculture as a free service to sellers and buyers, and each bale submitted is given an official grade. Many buyers prefer to do their own classing, however, and much of the cotton in trade is bought and sold on grade and staple determined by the buyer or his classifier.

Local markets are maintained where cotton is ginned, and the local buyer may be the ginner, an independent buyer or a merchant or banker to whom the cotton grower is indebted. Buyers for mills are especially active at gins near the spinning mills and they sometimes buy in local markets in areas remote from the mills, especially in areas producing sizeable volumes or where cotton with special qualities is produced. Co-operative marketing agencies also have buyers in the local markets. Much of the U.S. cotton has gone into the government loan program since it was established in 1933 and such cotton is not purchased by a local buyer but is transferred from the gin to approved warehouses, after which the grower obtains a loan on the negotiable warehouse receipt. Central markets are located in larger cities and merchants and shippers operating in these markets buy from local markets and sell to mills, both domestic and foreign. These merchants do not engage in the physical handling of cotton but trade in negotiable warehouse receipts and are therefore dependent upon the warehouses for storage and handling of the cotton. Each central market serves its members in providing market information and in handling purchases and sales on the futures market.

Central markets determine the basis, which is the relation of spot-market price to futures-contract price. The base price in the U.S. is the price of middling one-inch cotton, and the basis sheet lists premiums and discounts for other lengths and grades of upland cotton that may be delivered in place of middling inch. Premiums and discounts are related to the supply of the various

kinds of cotton and the basis varies throughout the season.

Manufacturers' markets are not assembled markets but exist in the spinning-mill area in the person of mill buyers. Some of these are professional buyers; others, officers of the mills. Purchases are made from central markets as a rule, usually for forward delivery at a price agreed upon when the purchase is made. A survey after World War II showed that about 20% of the cotton used by U.S. mills was purchased through mill buyers, agents or other subsidiaries; 64% was obtained through central markets; 10% through ginners and other local first buyers; 4% through the Commodity Credit corporation (a government loan agency); 1% through co-operatives; and 1% direct from growers.

All of the physical markets described above utilize the futures market for lowering their risk in handling a commodity subject to price change (see FUTURES). Cotton merchants hedge their purchases of cotton bought at fixed prices which they have not sold at fixed prices by selling cotton contracts on the futures market to the extent that such sales offset in quantity actual cotton bought. In order to hedge sales of actual cotton which was sold at fixed prices but which was not bought at fixed prices, merchants purchase sufficient contracts on the futures exchanges to offset in quantity the actual cotton sold.

**BIBLIOGRAPHY.**—H. B. Brown and J. O. Ware, *Cotton* (1958), contains comprehensive bibliography; Frank D. Barlow, *Cotton in South America* (1952); *Yearbook of the New York Cotton Exchange* (annually); *Cotton Year Book* (annually). See also Read P. Dunn, Jr., series on foreign trade in cotton, published by the National Cotton Council of America.

Current production statistics are summarized annually in *Britannica Book of the Year*.

**COTTON BELT**, a name traditionally applied to the cotton-growing part of the old south in the United States. As a crop term it was extended in the 1930s to include western irrigated areas.

There are four major areas of cotton production in the United States. The southeastern area extends from the Carolinas to the Mississippi delta and includes parts of Virginia and Florida. This was the original zone of cotton production in the south. In the 19th century up to one-fourth of the cropland was in cotton; by the second half of the 20th century only 1 crop acre in 11 was in cotton, and the area had one-sixth of the national crop. Yields per acre were moderate (350–400 lb.), and staple length typically  $1\frac{1}{8}$  in. The small farms and hilly landscape are not suitable for mechanization, and farm abandonment and consolidations have been widespread; beef cattle, dairying, broiler production, peanuts and soybeans became of increasing importance. The crop remained significant on the inner coastal plains and the Piedmont of the Carolinas and Georgia and in north Alabama, but few farms had as much as 20 cotton acres each.

The Mississippi lowland or delta includes the cotton areas in Missouri, Arkansas, Tennessee, Mississippi and Louisiana, plus a few acres in Illinois and Kentucky. Cotton remains "king" on the flat and very fertile alluvial soils. In the early 1930s cotton was planted on more than 40% of the crop acres; although by the 1960s cotton acreage was only half as much, production increased slightly, to 25%–30% of the national crop. Many farms had over 100 cotton acres and were almost fully mechanized. Per acre yields were about one bale (500 lb.) and staple length  $1\frac{1}{8}$  in. Corn, soybeans, rice and beef pastures increased in acreage.

In the southwest (Texas and Oklahoma), cotton long has been important. In the Blackland prairie and Corpus Christi areas it is raised with the aid of natural rain much as in the southeast, but farms are larger, many with more than 100 cotton acres. The cotton raised in the flat to rolling lands of southwest Oklahoma and nearby parts of Texas is also a rainfall crop, but irrigation is necessary in the lower Rio Grande valley and in the Lubbock basin of the West Texas high plains. On irrigated farms cotton acreages are large and production is mechanized. Yields per acre average about 300 lb., and the staple length is  $\frac{7}{8}$  to  $1\frac{1}{8}$  in. The southwest had more than two-fifths of the national cotton acreage in the early 1960s and nearly one-third of the production.

The western and newest part of the cotton belt is in the irrigated

lands of New Mexico, Arizona and especially California. Cotton experiments began in Kern county, Calif., in 1916, but the major acreage expansion came in the 1940s. By the 1950s this area, with less than one-tenth of the national acreage, had nearly one-fifth of the production. Up to 2 bales per acre were raised, with staple lengths of  $1\frac{1}{8}$  in. and over. Cultivation is highly mechanized. This area also raises the small U.S. crop of American-Egyptian cotton, with yields of a bale per acre and staple lengths averaging over  $1\frac{1}{8}$  in. See also COTTON.

See Ladd Haystead and Gilbert C. Fite, *The Agricultural Regions of the U.S.* (1955); U.S. Department of Agriculture, "Land," 1958 *Yearbook of Agriculture* (1958). (J. A. TR.)

**COTTON FAMINE** (1861–65), which devastated the Lancashire cotton industry, was the result of the American Civil War, when the supply of U.S. cotton, which then formed 85% of Lancashire's total consumption of raw material, was almost entirely cut off. The years 1859 and 1860 had been a period of great activity in the cotton trade: large stocks of cotton had been imported, and the stocks of yarns and manufactured goods were unusually large. Had there been no war it is probable that the trade would have been compelled to face a reaction involving a severe spell of depression and short time. It was not therefore till well into the autumn of 1861 (the blockade of the southern ports was established in July of that year) that the pinch first began to be felt in Lancashire. The rise in the price of cotton, which had been the first effect of the war, had enabled the spinners and manufacturers to dispose of large stocks of goods, and it was probably the cessation of demand rather than the lack of supplies of the raw material which first began to produce stagnation in the trade. In the opening weeks of 1862 trouble became acute. Widespread appeals for contributions were sent out with very satisfactory results. In all nearly £1,750,000 was distributed by various relief committees, not including contributions in kind (which were estimated at about £112,000 in value) and relief granted by the boards of guardians. In three years the latter spent just under £2,000,000. The total loss incurred by the whole trade in wages, profits, etc., is incalculable, but must have exceeded £10,000,000. By the time the large prefamine stocks had disappeared (some cotton was actually reshipped to the northern states) other supplies, especially from India, were coming into England, though in comparatively small quantities. The quality of this cotton proved exceedingly unsatisfactory. And although the cotton from Egypt, where quantity was comparatively small, proved better in quality even than U.S. (except Sea Island), at best, however, the total supplies were never more than enough to keep the industry running about half-time. Even after the conclusion of peace in April 1865 it was a long time before supplies reached anything like normal.

See R. A. Arnold, *History of the Cotton Famine* (1864). (A. BR.)

**COTTON GRASS** or **COTTON SEDGE** is the name applied to species of *Eriophorum*, a genus of the sedge family, Cyperaceae

(q.v.). There are about 15 species, about 10 being North American. They are generally found on wet and boggy moors, and are sometimes planted in the bog garden. The flowers are massed together into heads and each has four or more hairlike bristles at the base. After fertilization these grow out into long, conspicuous, cottony hairs which serve to distribute the seed which is contained in a small dry achene. The alpine cotton grass (*E. alpinum*) and the slender cotton grass (*E. gracile*) occur both in Great Britain and in North America. The Virginia cotton grass (*E. virginicum*), with dingy brown, rarely white, hairs, grows from Newfoundland to Manitoba and

COTTON GRASS (*ERIOPHORUM POLYSTACHION*), ABOUT ONE-THIRD NATURAL SIZE. SHOWING MATURE FLOWER CLUSTERS CLOTHED WITH WHITE COTTONY HAIRS

southward to Florida and Nebraska. The sheathed cotton grass (*E. callithrix*), found from Newfoundland to Pennsylvania and Wisconsin and northward to the arctic, and also in Asia, forms in Alaska the summer food of reindeer.

**COTTON MANUFACTURE.** Raw cotton has few uses; processed, or manufactured, cotton has many. This article tells how raw cotton fibres, which are about as fine as human hair and from  $\frac{1}{2}$  in. to 2 in. long, are changed into useful products. The main sections of this article are as follows:

#### I. Manufacturing Processes

##### A. Production of Yarns

1. Preparation for Spinning
2. Spinning
3. Doubling
4. Finishing and Making-Up

##### B. Production of Fabrics

1. Preparation for Weaving
2. Spooling
3. Warping
4. Slashing

##### C. Converting of Cotton Goods

1. Scouring and Bleaching
2. Dyeing and Printing
3. Finishing

#### II. Varieties of Cotton Products

1. Yarn
2. Varieties of Cotton Yarns
3. Varieties of Cotton Fabrics

#### III. Economic Development of the Cotton Industry

1. Development up to 1914
2. Development After 1914
3. Machinery
4. The Uses of Cotton
5. Organization of the Industry

### I. MANUFACTURING PROCESSES

The vast bulk of the world's cotton is spun into yarn, which is marketed as such, especially as sewing cotton, or is made into fabrics by weaving, knitting, lacemaking or braiding. Some yarns, and most fabrics, are rendered more attractive and useful by a variety of converting processes, which include bleaching, dyeing and printing, and a wide range of finishing processes, both mechanical (*e.g.*, calendering, stiffening, glazing and raising) and chemical (such as mercerizing, parchmentizing, making crease resistant, waterproofing and rotproofing). The description below outlines the manufacturing processes; for further details see SPINNING; WEAVING.

#### A. PRODUCTION OF YARNS

**1. Preparation for Spinning.**—In some countries cotton is grown so near the mills that it can be ginned and carried to the spinner loose in farm wagons, but the usual practice is to deliver ginned cotton in highly compressed bales (*see* COTTON). The raw cotton contains 1%–2% of impurities such as soil, dust particles and bits of leaf and seed husk. A special type of impurity is caused by fibres that have failed to grow properly on the seed and are said to be immature or even dead. They have very thin walls and tend to form tangles that may enclose bits of leaf. These tangles are known as neps and are regarded as a major nuisance by spinners.

Once the cotton is received in the mill the following preparatory and spinning processes take place: (1) the highly compressed cotton is reduced to the greatest possible state of division, and impurities are removed; (2) the fibres are formed into a rope, or sliver; (3) the slivers are drawn between rollers to attenuate them and are sometimes combed to arrange the fibres in parallel rows and to increase the regularity of the material; (4) sufficient twist is inserted into the attenuated slivers, by now called roving, to make a firm thread; (5) where required, two or more threads are combined into a folded yarn; and (6) the yarn is "finished" and prepared for shipment.

The principal machines used in spinning preparation and spinning are: bale breakers, openers, pickers (U.S.) or scutchers (Great Britain), for cleaning and blending the cotton; carding engines, draw frames and, for high-quality yarns, combers, which

remove further impurities and form the fibres into a sliver; flyer frames for drawing and twisting; either ring frames or mules, for spinning, and, where folded or ply yarns are produced, winders and doublers, or twisters; cleaning and gassing (singeing) frames; and reels and bundling presses.

**The Bale Breaker.**—The raw material, in the form of hard compressed slabs from the bale, is fed by hand into a hopper, from where it passes to a system of spiked and latticed conveyor belts. These belts carry the cotton under a spiked roller and then return most of the material to the hopper so that the tearing process can be repeated. As a result of the repeated passes between the two sets of spikes the cotton is reduced to a fairly fluffy state. Besides breaking down the raw material, which has been chosen from bales of different grades so as to give the desired quality of yarn, the bale breaker also mixes the raw cotton. In most cases mixing is completed satisfactorily by the machinery through which the cotton subsequently passes; sometimes, however, in mills that spin fine yarns, mixing is assisted by building up a stack of cotton from the breaker in horizontal layers and, after leaving it for two or three days to become aerated, pulling it down in vertical layers. From the bale breaker the material goes to the opener.

**The opening and cleaning range** employs various combinations of machines that have several features in common. Their function is to loosen, or open, the tufts of cotton as delivered by the bale breaker and mixing machines, and to separate more of the dirt and trash from the clean cotton. Spiked and other endless lattices are used to lift and convey the mass of cotton over short distances from one part of a machine to another. Beaters break up the tufts, and rotary cages sift the dirt and trash. The beater is a rotary shaft from which protrude blunt spikes or flat-ended blades that strike the cotton as it passes round them. It was once considered sufficient to clean and fluff up the cotton. By the 1950s, however, blending had become equally important because of the advent of high-speed spinning machinery and the more precise methods of measuring and specifying the qualities required of the fibres and yarns. More use came to be made of hoppers for storing and feeding loosened masses of cotton, of automatic devices for weighing and feeding so that blends can be made in exact proportions, and of air currents for conveying loose cotton through lengths of trunking.

**The picker (scutcher)** is the last machine in the opening and cleaning line and, besides picking, has the additional function of forming the loose cotton into a sheet (the lap) nearly an inch thick and rolling it up into a package weighing 40–50 lb. The regularity of this lap is important for the success of subsequent processes, and a device known as an evener motion is used to control the rate at which cotton reaches the lap-forming mechanism so that across and along the length of the lap there is, as near as possible, the same weight of cotton per inch.

**The Carding Engine or Card.**—Here the elimination of impurities, including neps, is completed. The picker lap is reduced for a brief moment to gossamer fineness and then rolled into a soft rope called a sliver. Trash and short, broken and immature fibres are jettisoned but the machine must be carefully set and supervised so that it does not create more neps than it removes.

At the start of the carding operation, the picker lap is unwound by a small roller and presented to a taker-in roller, or licker-in. This consists of a series of fine-toothed circular saws mounted together on a shaft. The teeth move at a speed of about 1,000 ft. a minute and tear away small bunches of fibre from the lap. These are stripped from the licker-in by a cylinder, about 40 in. in diameter, that is covered with closely set steel wire teeth and revolves at about 2,000 ft. a minute. Above part of this cylinder are narrow bars, called flats, that are carried by an endless belt and are covered with wire teeth similar to those on the cylinder but pointed in the opposite direction. The cotton passes between the cylinder and the flats; the distance between them is set to about seven one-thousandths of an inch. Since the flats move in the same direction as the cylinder but only at two to three inches a minute they have a retarding and combing action and pick up the trash, short fibres and neps. This material is removed

from the flats by a comb and a rotary brush and is deposited in a waste receptacle. The good cotton is held between the wire teeth on the main cylinder, from which it is doffed by a smaller cylinder. This doffer also has wire points, facing into those of the main cylinder, but travels at only about  $\frac{1}{15}$ th of the speed. A rapidly rocking comb takes the cotton fibres from the doffer in a continuous sheet nearly as fine as a spider's web. The web is immediately formed into a sliver by a pair of rollers that pull it through a trumpet- or funnel-shaped hole and pass it on to a mechanism that coils it into a tall can.

Formerly, the carding operation created a very dusty atmosphere in its part of a cotton mill and the dust gave rise to byssinosis, a form of pneumoconiosis (*q.v.*). As a result of research work, the carding engine was modified so that no dust can escape into the atmosphere and it has become possible to have an atmosphere in the card room that is cleaner than the outside atmosphere.

**The Draw Frame.**—It is only necessary to attenuate and twist the card sliver to produce a yarn. The initial processing at this stage is carried out on the draw frame. Steps are taken to make the sliver more regular and to arrange the constituent fibres in approximately parallel order. Four, six or eight card slivers are blended into one on the probability that a thick place in one sliver will balance out a thin place in another. To prevent the combined sliver from becoming thick, the blending is accompanied by attenuation, or drafting, as a result of which the product becomes four, six or eight times as long as but no thicker than one of the card slivers. The draw frame has four pairs of smooth, leather-covered rollers arranged fairly close together in four rows. The pairs are driven so that the speed of rotation increases from row to row until the front pair is moving four, six or eight times as fast as the back pair, depending on the number of card slivers being fed into the machine. Because of the increasing roller speed, the individual fibres slip forward as they pass between the pairs of rollers and are also pulled straight. The increasing amount of parallelism of the fibres becomes apparent in the increased lustre of the draw-frame sliver, which is quite silky. The process may be repeated two or three times on the assumption that the regularity of the sliver is improved every time the sliver passes through the draw frame. Spinners now realize, however, that the repetition can be overdone.

**The Comber.**—For high-quality and fine (*i.e.*, thin) yarns, it is usual to remove 5%–15% or even 20% of the shorter fibres as this enhances the "spinnability" of the remainder. To remove the fibres the slivers are recombined into small rolled-up laps that are fed to the comber. At regular intervals a lap is advanced so as to present a fringe to a set of combs that pass through the fringe and take out the loose, short fibres. These are detached from the combs and reserved for use in spinning a coarser yarn. The combed fringe is then pushed forward and combined with the tail of the previous fringe. The machine usually has six combing units, and the six combed laps are combined and drafted into one combed sliver, which may then be passed through the draw frame again.

**Drafting Machines.**—To complete the attenuation of the sliver the same principle of drafting by means of rollers is exploited in a series of machines known collectively as speed frames and individually as slubbing, intermediate, roving and fine jack frames. One machine drafts (*i.e.*, reduces the bulk and weight per unit of length) the sliver about six times; the thinner product, known as roving, is passed to the next machine, where it is drafted another six times and so on down the line of frames. During the operation, the opportunity is taken to make the products more regular by blending, two slivers or rovings being fed together to the rollers. The drafted product, at each stage, must be wound into a package that is convenient to handle and set up on the next machine. It must also be twisted enough to make it stand gentle pulls during the winding and unwinding but not enough to hinder drafting. The twisting is performed on flyer spindles. The package, called a bobbin, is built up on a wooden support, also called a bobbin, that fits loosely on a vertical spindle to whose top is fixed a hollow, inverted U-shaped device, the flyer. The

roving passes through the flyer to the bobbin, which it drags round; because of the high speed of rotation of the spindle and flyer, twist is inserted in the roving as it passes from the flyer to the bobbin. The bobbin rests on a frame through which the spindle protrudes; the frame rises and falls so that the coils of roving are laid down in regular succession over the major part of the length of the bobbin.

The limit to which the traditional roller drafting (invented by Lewis Paul in 1738) can be carried in one stage depends on the staple length of the cotton and the distance between nips of the roller pairs; the maximum attenuation possible with traditional drafting machines is a draft of about six. If the pairs of rollers are too close together many fibres will be ruptured. If they are too far apart many fibres will be floating loose between them, with a risk that the product will build up unevenly. This risk has led machine makers to avoid relying on two pairs of rollers to effect the desired draft and to divide the draft between three or four pairs, each pair revolving faster than the pair behind it. These three- or four-line roller systems are the rule, especially on the spinning frames proper. At the turn of the 20th century it was realized that if the floating fibres could be controlled much longer or higher drafts would be feasible; many long or high drafting systems are available. In some, the space between the pairs of drafting rollers is filled out by inserting thin rollers that support the product as it is being drafted. In others a pair of endless traveling belts (called aprons) is used as support; small trumpet-like supports are also used. These systems of fibre control are usually fitted to the spinning machine and have rendered some of the traditional speed frames redundant. Drafts of 30 or more, instead are 6, are currently attained in spinning, without detriment to yarn quality. Indeed, experimental and testing machines are in use that spin directly from card sliver with a draft of 900 and more.

**2. Spinning.**—Spinning machines continue the blending and drafting begun on the speed frames, but they also insert twist in the desired direction and to the desired extent and wind the yarn into packages—known as cops, or bobbins—that vary in size according to the purpose for which the yarn is intended. Two types of machine are used: the mule, which was invented by Samuel Crompton in 1779 and is a cross between J. Hargreaves' spinning jenny (1764) and R. Arkwright's water frame (1769); and the ring frame, which was invented by John Thorp in the U.S. in 1828 and which by the early 1960s had almost entirely replaced the mule.

**Mule Spinning.**—In the early 1960s mule spinning was obsolete in the United States and declining rapidly in England and other parts of the world (see *Economic Development of the Cotton Industry: Machinery*, below). However, many British spinners claim that, for some purposes, the mule produces a better yarn than the ring frame and it is still used for spinning the finest yarns in numbers above about 200.

In the mule the action is intermittent, twisting and winding being separate operations. The roving from a creel of bobbins is passed in the usual way through a roller drafting system to a bare spindle mounted on a carriage that runs on rails. The carriage may accommodate as many as 1,200 spindles in two groups on either side of the driving mechanism. Spinning begins with the carriage close to the drafting rollers. As the drafted roving is delivered to the spindle the carriage moves away and the rapidly revolving spindle inserts twist. The carriage moves a distance (known as the draw or stretch) of 54–66 in. and then stops an instant while the spindles continue to revolve. It then moves back toward the rollers and during this inward run the stretch of twisted yarn on the spindle is wound into a cop of the desired shape.

**Ring Spinning.**—In this process the drafted roving is twisted into yarn and wound onto a bobbin simultaneously and continuously as in the flyer frames except that on the ring frame the flyer is replaced by a smooth ring with a flanged upper edge over which is sprung a small C-shaped piece of steel wire or plastic known as a traveler. The spindle, carrying a wood, paper or metal support for the bobbin (itself known as an empty bobbin), projects vertically through the horizontal ring. The drafted roving runs

from the drafting system to the traveler a few inches away and then to the bobbin; as the latter revolves with the spindle the yarn drags the traveler round the ring and the twist is thus inserted. The ring is mounted on a rail that moves up and down so that the yarn is laid down as a close succession of coils on the bobbin. The size of the bobbin and the degree to which the yarn is twisted are governed by the diameter of the ring and weight of the traveler.

A fundamental difference between the ring and mule methods of spinning is that the length of the element of yarn that receives twist at a given moment is only a few inches on the ring frame but is 54–66 in. on the mule. This may account for some of the alleged differences in yarn quality.

**3. Doubling.**—For many purposes two or more single spun yarns are twisted together (doubled), usually by ring and traveler or flyer mechanism but, as attenuation is not required, the drafting system is replaced by feed rollers. The singles may be run through a trough of water. Wet doubling produces a firm and smooth yarn, but dry doubling gives a softer product.

Further processes include the production of cords; for example, by twisting together three doubled yarns. The variety of yarns that can be produced depends on the direction and degree of the twist inserted in the component "singles" and in the various folding, or plying, operations that follow. An endless range of novelty or fancy yarns can be produced by plying together different types or colours of single yarns, by feeding one yarn to the twisting device much faster than the other so that it corkscrews around it, or by feeding one yarn alternately fast and slowly so that the product is uneven in thickness (see *Varieties of Cotton Products*, below).

**4. Finishing and Making-Up.**—When lustre and smoothness are desired, the yarn is passed several times through a gas flame or red-hot tube at such a speed that the fibres projecting from the surface are burned off without damaging the rest of the yarn. This process is known as gassing, or singeing. Such yarns may also be polished by repeated calenderings between a pair of heavily loaded rollers.

## B. PRODUCTION OF FABRICS

Weaving is the process by which longitudinal yarns, known as the warp, are interlaced at right angles with transverse yarns, called the filling or weft, by means of a loom. The discussion below deals with the principal processes that take place during the weaving of cotton goods.

**1. Preparation for Weaving.**—Yarn from the spinning room must be specially wound for the weaving machinery, and its preparation depends on whether it is to be the warp or the weft.

The filling yarn (weft) is sometimes sent to the weave room on the bobbins on which it left the spinning frame, but in the modern process much yarn is rewound onto cones and then into the packages (called cops, quills or pirns) demanded by modern automatic looms. The second part of the rewinding process is carried out by automatic quill winders that tightly wind nearly double the amount of yarn that can otherwise be wound on a quill. Rewinding also provides an opportunity to break out weak places and join up the good yarn; to facilitate this, the operative usually wears on the back of his thumb a little device for tying uniform knots.

Warp yarn needs more preparation for the loom and is usually spooled, warped and slashed (sized).

**2. Spooling.**—The function of the spooler is to unwind the yarn from the bobbins onto which it was spun and to rewind it on a large package called a cheese, which weighs as much as ten pounds. The machine consists of a long frame that supports a row of bobbins in a vertical position on either side and, above them, a row of cheeses arranged on either side of a horizontal drum. A knot-tying device, called a traveler, circles a track on top of the frame at preset intervals (usually about three minutes). When it has attached the yarn from the full bobbins to the cheeses, the arms that hold the cheeses press them against the drum, which is revolving at high speed. This drives the cheeses by friction and makes winding possible at speeds of 900–1,200 yd. a minute. When the bobbin runs out, the yarn breaks or the cheese fills up,

the cheese arm lifts the cheese free of the drum. Empty bobbins are dropped on a conveyor belt and new ones fall into place from a reserve.

**3. Warping.**—The purpose of warping is to run 200–400 equally long threads side by side onto a single beam. The sheet thus formed is then finally prepared for weaving in the slasher.

The full cheeses of yarn are doffed from the spooler and taken to the warper. There they are put into the warp creel, a framework of vertical metal bars, each of which holds 9–12 cheeses. Two creel sections are placed in the form of a V with the cheeses on the outside and the junction pointing toward the horizontal beam onto which the yarn is to be wound. Because of the frailty of the yarn, the motor driving this take-up beam starts slowly; it also stops automatically if the yarn breaks. In the high-speed warper both sides of the creel are fitted with spring cores to hold the cheeses, and operatives place cheeses on the inside while the winding is taking place. As soon as the outside cheeses are exhausted the position of the creels is reversed.

**4. Slashing.**—In the slasher (known as a tape frame in England) several beams of yarn from the warper are combined on one loom beam to give the number of warp yarns (several thousand) necessary for the loom; they are then coated with size (mostly starch) to prevent chafing during weaving.

The warper beams are mounted horizontally across the back frame of the slasher and are brought together in a single sheet at a condenser comb, or bar. The sheet is then treated with size solution, usually by running it between rollers below the surface of the size in the size box. It is important that the warp yarn should pick up a correct and constant quantity of size, about 7%–10% for good weaving, and so the viscosity and concentration of the solution must be watched carefully. As a result of research work conducted in the 1950s, many tape frames in England were fitted with automatic controls. The basic ingredients of the size, chosen for its cheapness, is usually cornstarch in the U.S. and potato starch, flour or sago in the U.K. Other ingredients—for example, softeners, lubricants, emulsifiers and materials to prevent the growth of mildew—are usually present in small quantities. A typical formula for gingham is 80 lb. of starch, 5 lb. of softener and 100 gal. of water, which makes 125 gal. of size.

After leaving the size box the sheet goes to the drier, which, in the U.S., usually consists of two or three steam-heated metal-surface cylinders. The aim in drying is to leave the yarn with a moisture content of about 8%–10%; complete dryness is avoided. When the sheet emerges, the yarns are stuck together with the hardened size solution and have to be split apart by rods and combs; the sheet is then wound on a loom beam and stored until needed for weaving.

In the 1960s homogenizers were replacing the kettles in which the size previously had been cooked. These render the material homogeneous without cooking and make it possible to use pear-starch, which is cheap, instead of the more expensive thin-boiled starch. In some mills hot-air driers are used instead of steam cans. Although this procedure is somewhat more expensive, it has two advantages over the older method: the sheet can be separated into individual yarns while still wet, thus avoiding the ragged edges caused by separating them when they are dry and the dried yarn is perfectly round, whereas if it is pressed against a metal cylinder it emerges flat on one side.

**5. Action on the Loom.**—The warp is brought to the back of the loom on a beam that carries the number of ends needed to give the desired width and density (ends per inch) to the woven fabric. Each end is threaded through an eye in a set of heddles, or healds, and between the teeth of a fine comb, known as a reed, before being secured at the front of the loom, usually to the ends of a previous warp. A heddle is a string or wire with an eye at its midpoint; a large number of heddles are stretched across a wooden or metal frame that is as wide as the loom, and several of these frames, or shafts, are suspended one in front of another at the back of the loom. Mechanism is provided for alternately lifting and lowering the frames so that a lozenge-shaped gap, called the warp shed, can be created between warp threads that are up and those that are down.

The filling (weft) is brought to the loom as a tightly wound package inserted in a shuttle; the shuttle is struck by the picking device and made to pass on the smooth track (race board) of the sley. The sley is an apparatus that extends across the loom and rocks to and fro, being pivoted to a shaft in the lower part of the loom. It carries the reed and, just below this, the race board.

The picking device is usually a strong stick, faced at its striking end with buffalo hide or other wear-resistant material. The other end is mounted in the loom mechanism, from which, by means of a cam, it is made to give a powerful blow to the end of the shuttle. For a long time engineers have considered this traditional picking to be quite inefficient. The aim is to carry across the loom a short length of yarn—say 30–120 in.—whose weight is negligible, but a filling package weighing several ounces is put into a much heavier shuttle and picked hundreds of times before it is used up. The force required to insert filling at a given speed increases proportionately with the cube of the weight of the filling package, so the traditional method wastes an enormous amount of power. It is not surprising, therefore, that in the mid-20th century other methods of inserting filling were made available. In some, packages of filling yarn are mounted at both sides of the loom and the traditional shuttle is reduced to a bulletlike gripper, about the size of a man's small finger, that engages the end of the filling as it flies across the loom and releases it at the opposite side. In other new types of loom, puffs of air are employed to carry the filling.

As soon as the shuttle passes through the warp shed, the beddles reverse and the shuttle is picked back again, this time riding over the warp ends that it passed under on the forward journey. At each pick, the length of weft that has escaped through the eye of the shuttle is pushed up tightly against the fell of the woven cloth by the reed. This is known as beating up. The cloth is wound tightly on a roller and, meanwhile, the warp beam is turned slightly to let off more warp to replace that already made into cloth. All these operations—the letting off of warp, the forming of the shed, the picking of weft, the beat up and the take-up of the cloth—must work in harmony and at speeds up to 200 or more picks a minute for cloth about one yard wide. The adjustment of a loom is aptly called tuning.

The simplest weave is a "one over, one under" interlacing of warp and weft. The effect of diagonal lines, known as twill, is introduced into a fabric by making the weft go over two or three and under one end in the first pick, and over a different set of two or three ends in the second pick, and so on. Patterns can be woven by arranging groups of coloured ends on the warp beam—this being the best way to produce stripes—or by using two or more shuttles with wefts of different colours. Colour-bordered tablecloths and cloths with coloured squares are produced in this way. By means of a dobby, a mechanism that can manipulate about 25 heddle frames to effect more complex shedding arrangements, an almost endless variety of geometrical patterns can be woven—checks, diagonals and so forth. Even more elaborate is the Jacquard mechanism, which is used to control the shedding of individual warps rather than regularly deployed sets of them; this makes it possible to weave floral and other nongeometrical patterns. Another method of weaving uses two warp beams, one of which lets off its yarn faster than the other so that at the beat up the longer pieces of yarn form into loops between the short pieces. Fabrics such as turkish toweling are made in this way. All these methods are used all over the world; some of the many fabrics manufactured are listed below under *Varieties of Cotton Products*; *Varieties of Cotton Fabrics* or are described in separate articles.

**6. Other Types of Production.—Knitting.**—Much cotton yarn was formerly knitted into cheap stockings and socks, but by the mid-20th century the man-made fibres were providing more attractive products. However, cotton continued to be used largely for comfortable underwear that was either fashioned from knitted fabrics or knitted as entire garments. (See *KNITTING*.)

**Lacemaking.**—Some of the finest cotton yarn is manufactured into lace, ranging from curtains to trimmings.

**Braiding.**—Other trimmings and articles like shoestrings are made by braiding, in which yarns are interlaced at an angle less than 90°. Sometimes this is done about a core, a very familiar example being the braided insulation of electrical wire (flex). The operation of braiding recalls the old-time maypole dance, the separate packages of yarn corresponding to the dancers and the central core to the pole.

### C. CONVERTING OF COTTON GOODS

Only a small percentage of woven cloth is sold to the consumer in the condition in which it leaves the weave shed; i.e., in the loom state or the gray. Much of it is bleached, dyed or printed and subjected to various finishing treatments, the procedure chosen depending on the construction of the fabric and the use for which it is intended. A brief outline of some of the more important operations follows.

Usually the gray goods are received from the weaver in lengths of 120 yd. or 240 yd. The pieces are inspected for imperfections, marked with a lot number for identification purposes and sewn end to end to permit processing in continuous lengths. They are then passed over a gas or electric singeing machine, where the short fibres protruding from the surface of the cloth are burned off. The goods may next go to a desizing machine, where the starch that was employed in sizing the warp yarns before weaving is removed. For this purpose enzymes that digest starch are often used.

**1. Scouring and Bleaching.**—Before cotton piece goods are bleached they usually are boiled for several hours with dilute caustic soda (sodium hydroxide) solution in a closed vessel, called a kier, to remove the natural oils, waxes and other impurities. Next they are rinsed, soured in a dilute solution of sulfuric or hydrochloric acid, rinsed, chemicked by being passed through a solution of sodium hypochlorite, piled in bins to permit the bleaching action to take place, rinsed, passed through a solution of sulfurous acid or other antichlor to remove the last traces of chlorine, again rinsed, passed through a water mangle to squeeze out excess water and dried on a set of revolving steam-heated cylinders, or cans. Bleaching can also be carried out in the kier by means of an alkaline solution of hydrogen peroxide, after which the cloth is rinsed and dried. Sodium chlorite won favour as a bleaching agent because it is easier to control and the cotton is not overbleached and weakened (tendered) in the process. Many bleachworks practise continuous bleaching, the gray cloth passing in succession through a series of scouring, washing and bleaching units. (See *BLEACHING*.)

**2. Dyeing and Printing.**—Dyeing is often carried out in machines in which a batch of the cloth, stitched end to end, is carried through tanks of hot dye liquor. In some machines a pair of rollers are submerged in the liquor; the cloth travels between them and is padded with the dye. Continuous machines are also used. They consist of long tanks with a set of rollers at the top alternating with another set near the bottom. The cloth runs alternately over a top roller and under a bottom roller and so travels from one end of the tank to the other. Fabrics that are to be dyed in light or medium shades are bleached before dyeing. Bleaching is frequently omitted if the fabrics are to be dyed in dark shades. Printing is usually carried out on roller printing machines, although some fabrics are screen printed (see *TEXTILE PRINTING*). After being printed, the fabric is frequently passed through a steam chest, called an ager, and then through a continuous washer before being dried. The choice of dyestuff depends on its cost and the purpose for which the fabric is intended. Dyes that provide the highest degree of fastness to washing are used in articles such as handkerchiefs and children's frocks, those that provide fastness to light (i.e., resistance to fading) are used in sun blinds and curtains; and those that provide fastness to perspiration are used in coloured garments worn next to the skin. (See *DYES AND DYEING*.)

**3. Finishing.**—The white, dyed or printed goods are dried on steam-heated drums or in hot-air chambers and then finished. Finishing may be a mechanical process, assisted by starches, dextrans, gums, china clay and other agents designed to smooth, stiffen

and in other ways improve the feel (handle) of the cloth, or it may be a chemical process.

In mechanical finishing the two types of equipment used for applying the finishing agents are starch mangles and backfilling machines, the latter being designed to apply the finish to one side of the cloth only. After the finishing agents have been applied the cloth is partially dried, then passed over a stenter, or tenter, where drying is completed and the fabric is stretched to the desired width and straightened. On this machine the fabric is held taut by pins or clips as it passes through a drying chamber. The pins or clips are attached to endless belts and the distance between the belts gradually increases so that the fabric is stretched widthways. Various types of calenders are employed to give smooth, lustrous or embossed effects. These machines consist essentially of metal, paper or fibre rolls between which the cloth is passed under considerable pressure. A linenlike appearance is obtained by use of a beetle—a machine that drops heavy wooden posts on the cloth as it travels over a steel roll.

Controlled-shrinking machines of various types are employed to counteract the stretching effect of the preceding operations and thus to prevent the fabric from shrinking upon laundering. Certain fabrics, such as cotton blankets and flannelette, are run over a raising machine to produce a nap.

Chemical finishing is commonly applied to cotton goods before they are given a mechanical finishing. Chemical finishing consists of using certain chemicals to obtain specific effects, which are of great importance to the cotton industry since they make cotton a fashionable, rather than a purely utilitarian, material. The first truly chemical finish to be employed was mercerizing (*q.v.*), named after John Mercer, an English dyeworks chemist. In 1844 he discovered that when cotton is steeped in sodium hydroxide (especially of 18% strength) the fibres shrink in length, swell and become round in outline, and dye to a deeper shade. With this process he produced fabrics with dark, puckered spots on a paler ground; some types of modern seersucker fabrics are their descendants. Later (1889–90), Horace Lowe, a bleachworks chemist working near Stockport, Eng., discovered that if the cotton (yarn or fabric) is held in the caustic soda so that it cannot shrink, or is stretched to its full length while still in the alkali, it acquires a silky lustre. This is the really valuable effect of mercerization and the process is commonly applied to high-quality cotton fabrics such as poplins.

Strong sulfuric acid has a parchmentizing effect on cotton; for instance, it is used to give the swiss-organdy finish in which the cotton fabric becomes stiff and semitransparent. Other chemicals are used as proofing agents. Cotton fabrics are made waterproof or water repellent by depositing an alum soap within and between the fibres, or by the surface action of one of the silicones. A variety of efficient antiseptics is available for making cotton goods rotproof. In the early 1960s the problem of making fabric fireproof without making it uncomfortable to wear was at last within sight of a satisfactory solution, due to the discovery of a range of organic derivatives of phosphoric acid.

Perhaps the discovery that has had the most profound effect on cotton and rayon finishing was the outcome of research into crease resistance, carried out in 1918–39 by an English firm that discovered a way of producing a synthetic resin within the fibre by combining chemicals like formaldehyde and urea. These resin treatments became almost legion and are the basis of drip-dry, minimum-iron and related finishes.

(J. C. WL)

## II. VARIETIES OF COTTON PRODUCTS

**1. Yarn.—Yarn Numbering or Count System.**—The fineness of yarn is measured, in English-speaking countries, by the number of hanks of yarn that weigh one pound. In the U.S. this is known as its number, in the U.K. as its count. A hank is 840 yd. long, and so, for example, one pound of no. 10 (10s count) cotton yarn would unwind to 8,400 yd. In other countries metric units are used. It is difficult to compare cotton yarns with those of wool, rayon and silk since the hank of wool in English-speaking countries is 560 yd. and the number for silk and rayon is based on the weight in grams of 9,000 m. of yarn. Thus numbers for cotton

and wool are based on length per unit weight and are higher for fine yarns than coarse, and numbers for silk and rayon are based on weight per unit length and the fine yarns have the small numbers. Since mills tend to spin, and manufacturers to use, more than one type of fibre, a change-over to a universal system based on weight in grams per kilometre, or per ten kilometres, for all fibres was being widely considered in the early 1960s.

**Yarn Twist.**—Traditionally such terms as regular, reverse, twist-way and weftway were used to describe the direction of twist in a yarn. These were found very confusing and so the practice of designating the twist Z-way or S-way according to the direction of slope of the stems of these capital letters became established; this plan was first suggested in the U.S. in 1934. The magnitude of the twist is recorded as the number of turns per inch or by a twist factor (loosely termed a constant or multiplier) determined by dividing the number of turns per inch by the square root of the count.

**Yarn Strength.**—The strength, or breaking load, of cotton yarn is measured by a tensile-testing machine applied either to a single yarn or to a lea (120 yd.) that is wound on a reel 54 in. in circumference; when leas are tested, the breaking load is applied to 160 yarns at the same time. The breaking load of a cotton yarn depends only to a minor extent on the intrinsic strength of a cotton fibre; the important factors are number and twist. Breaking load increases with twist up to a certain point and then declines. A useful basis on which to compare different cottons is the product of the lea strength and number; spinning conditions are best when this product is a maximum.

The number to which a given type of cotton can be spun commercially depends mainly on its staple length; the long cottons yield the finer yarns. Short Indian cottons spin up to about 16s, American cottons to 44s, Egyptian cottons to 150s and Sea Island cotton to 400s.

**2. Varieties of Cotton Yarns.**—Practically all U.S. spun yarns have Z twist; S twist is used for special purposes only, especially for making ply yarns. British spun yarn, when used for warp, has Z twist and is called twist yarn; yarn for filling (weft) is generally S twist unless otherwise specified.

The twist factors of warp yarns usually vary between 3.5 and 4.75. Filling yarns generally have fewer twists and are softer fuller yarns. Their factors vary between 3 and 4.25. Cloths that are to have a raised nap are manufactured from soft-twist fillings with factors from 2.50 to 3.

Condenser waste yarns used as weft yarn for such products as blankets, sheetings and twills are made from waste fibres that are carded, rubbed between a pair of endless leather belts into cylindrical or sliver form on a condenser card, and are spun on a condenser mule into 1s to 12s yarns without any drawing processes.

Knitting (hosiery) yarns are coarse, medium or fine-count single or ply yarns that are spun with a softer (knitting) twist than usual for weaving. Their factors vary from 2.50 to 3.

Ply yarn (U.S.), which is also called folded yarn (U.K.), is made by plying (doubling together) two or more ends of yarn. Usually the direction of twisting is opposite to that already used in the single yarns unless very wiry yarns are required; e.g., voile yarns. The majority are two-ply and are used where special strength is required, as in army ducks or airplane cloth.

Cable yarns are made of two or more ply yarns twisted together. Several varieties are made for cordage, twine, fish nets, etc. When made with SSZ twists, it is known as cable twist; that with a ZZS or SSZ twist is called hawser twist and is a tighter, wiry yarn. Both cable- and hawser-twist yarns are used in making fishing nets; in machine-manufactured nets they are used alternately to balance the shrinkage or contraction.

Thread or spool cottons used for sewing and embroidery are ply or cable yarns that have been specially twisted, combed and processed. Only Sea Island and the finest and strongest Egyptian cottons are used. After being twisted either wet or dry, the yarn is gassed to remove projecting fibres. It is then bleached or dyed; most yarn is also mercerized to give it a silky finish and finally

is waxed. If it is not processed it is described as soft finished. Crochet yarn is usually combed and is then carded before being softly twisted into a two-, three- or four-cord thread. Lace thread, which is made from Sea Island, Egyptian and fine American cottons, is supercombed, hard-twisted and gassed.

Coloured yarns are generally obtained by dyeing single yarns in solid colours. They can also be made from stock-dyed cotton fibres. A blended or mixture yarn, like that used in heather mixtures, is a plied yarn made by blending contrasting stock-dyed yarns. A mottled, or two-tone yarn, on the other hand, is a single yarn spun from a blend of different-coloured rovings. They are called mock twist (U.S.) or mock grandrelle (U.K.) and are used mostly in converts (finished fabrics) and mottled flannels. Sometimes roving, single yarns or ply yarns are printed throughout with a pattern of one or more colours. They are used in warp for decorative flannels, shirtings and tie fabrics and are called printed yarns. Yarn is also treated chemically to resist dye; this resist yarn is used, for example, in the manufacture of striped fabrics since after it is woven the ground cloth can be dyed without being affected.

Ply yarns with special effects are usually called novelty yarns.

Spiral yarn is made by plying two different-size yarns together and feeding the heavier yarn in excess so that it curls round the lighter one.

Chenille yarn is not a spun yarn but is cut from a specially woven cloth known as chenille weft fabric. The cut yarn has projecting tufts (cut-weft yarns) along its sides; the tufts are held tightly in place by the firm-woven warp ends. Ratiné yarn has loop effects throughout and is made of three or more different-size yarns that are unevenly plied. Bouclé yarn is similar to spiral yarn but is more exaggerated.

Slub yarn (himalaya, shantung, cloud, flake or snowflake yarn) is usually a simple yarn that has been spun unevenly by means of special gears at the spinning frame. The heavy patches in flake, snowflake, cloud or shantung are shorter than those in himalaya slub.

Core yarn is manufactured by plying a single cotton yarn with a heavy, bulky one (usually of Chinese or Indian cotton). It is used as filling yarn for blankets and, when napped, retains most of its strength. Woolen and cotton-and-woolen mixture yarns are also made with a cotton core. Rubber-core yarns are those with a round or flat rubber core, around which is wound a fine, single combed yarn (80s, 100s) and afterward a second fine yarn in the opposite direction. Such yarn is described by the number of yards that weigh one pound; e.g., 1,600-yd. yarn.

Union or mixed yarn is a single yarn made from cotton and wool or other fibres mixed or blended together. Part-wool yarns are made with varying percentages of wool and cotton and are manufactured into hosiery and underwear. The British name for a fine wool and cotton mixture is angola. Linen, cut rayon and silk are also used.

Coarse blanket yarns, usually heavier than no. 1, are known in the U.K. as bump yarns. They are measured in yards per ounce and are used as wadding or stuffer yarns to give weight in heavy quilt fabrics.

**3. Varieties of Cotton Fabrics.**—Cotton cloth traded in U.S., Canadian and British markets is classified in three broad divisions: (1) gray cloths—those woven of unbleached yarns and in some cases used in that state; (2) finished or converted cloths, which are gray cloths converted by bleaching, dyeing, printing and finishing; (3) woven coloured-yarn cloths, or mill-finished cloths—those woven and finished ready for use by the mills making them.

Another classification, with more general significance, is made according to use: the divisions then are: (1) apparel or clothing materials; (2) domestic or household goods, such as sheets, curtains, upholstery fabrics and towels; and (3) industrial fabrics. The last group includes tire fabrics, wagon covers, filter cloths for liquids and air, conveyor belts for mines, tentage, sailcloths and a host of other heavy fabrics. The most important types of cloth are described below and in separate articles, such as: BROCADE; BUCKRAM; CALICO; CAMBRIC; CHENILLE; CHEVIOT CLOTH; CHINTZ; CORDUROY; CRASH; CREPE; CRETONNE; DAM-

ASK; DIMITY; DUCK; FLANNEL; GABARDINE; GINGHAM; HOLLAND; MOIRÉ; MOLESKIN; MUSLIN; SERGE.

Airplane and balloon fabrics, two of the strongest cloths made, are plain woven from Sea Island, Egyptian or long-staple American cotton. The former is usually made from two-ply combed yarns (mercerized or plain). Balloon fabric is manufactured from extra-strong, long-staple cotton and is usually a single-yarn cloth.

Beach cloth is a strong cotton fabric with a loose weave; it is made of two-ply carded yarn. Bunting is a thinner, equally loosely woven fabric that, like beach cloth, is used chiefly for flags and draperies.

Bouclé is a rough-surfaced material woven from bouclé yarn (see *Varieties of Cotton Yarns*, above).

Cheesecloth and gauze are loosely woven, soft, light, plain-woven fabrics with a low thread count that are used as surgical dressings, tea bags, linings and bookbinding and for wrapping meat and cheese. A similar fabric, lightly stiffened, is tarlatan.

The rough pebbly surface of crepe is obtained in various ways: by using high-twist crepe yarns; by altering the yarn tensions during weaving, as for example in seersucker (crimp); by weaving fine warp and coarse filling in granite or mock leno weaves; or by finishing the cloth with caustic soda, printing and then embossing it with crepe rollers.

Donegal, originally an Irish peasants' homespun cloth, is a tweedy fabric made with coarse ply yarns twisted together.

The ribs in grosgrain, a close, hard-finish fabric, are formed by weaving a number of filling yarns as one. It is heavier than poplin and used for women's wear and trimmings.

Lawn is the basic fine, combed-yarn, plain-woven gray cloth used for converting into fabrics such as batiste, mull, muslin, nainsook and organdy. It is also the name of a starched crisp finish known variously as india lawn, victoria lawn and persian lawn (which is the finest made). Handkerchief lawn usually has a high thread count and a soft finish. Batiste is a highly mercerized, soft-finished, lightweight fabric used for lingerie, summer dresses and linings. (In the U.S. corset trade the term refers to a heavy, plain-woven, poplin-type fabric.) Nainsook is a bleached material; it is dyed pastel shades, soft finished and has a slight lustre. Such fabrics are used for underwear and infants' clothing and are frequently embroidered. British nainsooks are also known as white shirtings in the export markets. Muslin is made from lawn that has been bleached, dyed or printed. In the U.S. it is also the name of a finish given to white piece goods, such as sheetings. Organdy has a transparent, stiff finish and is one of the finest and sheerest fabrics made. It is usually bleached, dyed or printed, mercerized and given a very crisp permanent finish or a firm but temporary starched finish.

Leno fabrics have an open, gauzelike appearance that is obtained by causing certain warp threads, called doups, to swing across one or more adjacent warp threads in the course of weaving. Many beautiful fabrics are made by combining these cross weaves with other weaves. Marquisette is a sheer, leno-woven curtain fabric.

Osnaburg is plain woven from rough, uneven yarn and is a gray cloth with a low thread count. It is used for bags or is converted when it has a linenlike appearance. Hop sacking is similar to osnaburg but is made from cleaner yarn; it has a lower thread count, is given a soft finish and is used, unbleached or dyed, for men's wear.

In the U.S. piqué is always a carded- or combed-yarn fabric with narrow raised cords running warpwise. The very narrow corded material is known as pin wale; the heavier varieties are called bedford cloth, which is used for riding clothes, uniforms, car upholstery, etc., and is sometimes napped on the back for warmth. In Britain, piqués also have welts running weft-wise. Fancy piqués are compound fabrics made with quilted, or puffed, designs.

Print cloth is a carded-yarn, plain-woven, medium-weight staple fabric. It is made with yarns from 28s to 42s and is the fabric most widely used in the U.S. market for converting. It appears with different finishes under various names—such as printed

percale, cambric, organdy, printed shirting, muslin, crepe, canvas, chintz, interlining, bias binding—and is often used as a substitute for better cloth of the same name. The British fabrics known as Burnley printers are similar to print cloth. They are basic gray cloths used for converting into printed shirtings, white shirtings and drapery fabrics.

Dobby- or jacquard-woven fabrics in white or white and coloured yarns with quilted, raised or flat designs are used for counterpanes. British fabrics include patent satin or mitcheline, toilet and Marseilles, all compound fabrics (that is, two fabrics woven back to back and closely interwoven by bringing occasional warp threads from the back to the front and vice versa) that use fine yarns for the design on the face of the cloth and heavy yarns for the back cloth. Alhambra, honeycomb and crochet quilt fabrics are cheaper and lighter. U.S.-made quilt fabrics include a number of white and coloured fabrics of various weights with flat or quilted design that are generally referred to as jacquard bedspreads or according to the type of pattern used, such as colonial, peasant, dimity, crinkle stripe, etc. For ratiné, see *Varieties of Cotton Yarns*, above.

Sateens are smooth-faced cotton fabrics made with a satin weave, either warp faced or weft faced. Five harnesses (heddle shafts) are used. In weaving a warp sateen, each warp yarn floats over four weft yarns and interlaces with the fifth; for a weft sateen, the weft yarns float over the warp ones. The bindings or interlacings are as far apart as possible to obtain a smooth surface and avoid a diagonal line effect, and because of their smooth surface they take a highly lustrous surface when mercerized and schreinered (passed between special rollers). Sateens are used for linings, underwear and umbrellas, and are bleached, dyed and printed for numerous other purposes such as tropical suiting, uniforms and draperies.

British sheetings are made in plain or twill weaves. The regular plain-woven narrow sheetings are generally given a white finish and are strong and serviceable. Medium-weight narrow British sheetings are also called domestics. Wide bed sheetings are strong and have a high thread count. Twill-woven sheetings usually have heavy condenser weft yarns that give the fabric a soft texture. American sheetings are always plain woven, mostly of carded yarns. Narrow sheetings up to 40 in. are largely used for converting into various standard finished cloths including canvas, cretonne, suiting and crash. They are also used unbleached for grain and feed bags, as a base for coated fabrics and as covers for mattresses and cushions. Wide bed sheetings are sold unbleached as brown sheeting or are bleached and given a muslin finish.

Shirting is the general name for plain- and fancy-woven (any weave that is a combination or extension of a plain, twill or satin weave) fabrics such as poplin, broadcloth, oxford, harvard and grandrelle. It is given mercerized, chased and preshrunk finishes. White-finished shirting is also a general British term for white-finished fabrics that include longcloths, cambrics, muslins and various fabrics with pure-sized and back-filled finishes used in export markets. Poplin is a plain-woven fabric with about twice as many ends as picks so that its characteristic ribs run widthwise. The best qualities are made with ply- or single-combed yarns or with single-carded yarns; in the U.S., those made with fine yarn and a high thread count are called broadcloth. Poplins may be white, printed in solid colours or yarn dyed. The lighter varieties are used for shirtings and summerwear; the heavier are used for rainwear and sportswear. Oxford is heavier than broadcloth and is made with a fine warp and heavy filling yarn. Except in those cloths specifically called single-end oxfords, every pair of warp ends runs together and weaves as one with each pick. The fabric is generally bleached or dyed; British oxfords are made with stripes and checks. Harvard is a British shirting that has a reversible 2/2 twill and a soft texture. Grandrelle is also British and is woven with stripes of both solid-colour yarn and mottled grandrelle yarn. Madras is a lightweight fabric made with fancy stripes or all-over patterns that are jacquard- or dobby-woven from combed single yarn. Shirting woven from dyed warp and white or unbleached yarns is called chambray. In work chambray

the yarn is carded, the warp ends are usually blue and the material is starched. Dress chambray has combed yarns, is always bleached and is often preshrunk; when made with alternating white and coloured warp ends, it is called end-and-end chambray or end-and-end madras.

Ticking, a strong fabric, is used for covering mattresses, the best qualities being closely woven satin or twill weaves in various weights and constructions. It is usually warp striped but is also made in elaborate jacquard panel designs. Warp sateen, drills and lightweight narrow sheetings are made into cheaper quality converted ticking and are usually printed with floral designs.

British twilled cloths are generally called drills if formed by warp yarns, irrespective of the number of harnesses (heddle shafts), and twills if formed by weft yarns. American drill is always a three-harness, warp-faced twill that is medium or heavy in weight. Jean is similar to American drill but has a higher thread count. It is dyed and used chiefly for work clothing. The most important working fabric is denim, also known as dungaree cloth. It is a three-harness twill, usually woven with indigo-blue warp yarns and unbleached filling but also made in other colours, stripes and checks. It is a mill-finished fabric, usually starched and preshrunk, that is used for work clothing and sportswear.

(X.)

### III. ECONOMIC DEVELOPMENT OF THE COTTON INDUSTRY

**1. Development up to 1914.**—The earliest known piece of cotton cloth was discovered in excavations in the Indus valley of remains dated about 3,000 B.C.; cotton is also known to have been spun and woven in Peru by about 2,000 B.C. Before the Industrial Revolution the main centres of cotton manufacture were the cotton-growing countries: India, China, Turkey, the near east and Brazil, and at that time hand-spun and hand-woven cottons were imported on a large scale from India to Europe by the Dutch and English East India companies. Cotton manufacturing had, however, been introduced into southern Europe by the Moors in the middle ages; in England it took root in the 17th century in Lancashire, where a woolen and linen industry already existed.

The decisive revolution in the industry was brought about by the great inventions in the art of spinning, especially those made in England in the second half of the 18th century, and by the application of power, which led to the concentration of spinning in factories. Weaving underwent a similar revolution at a slightly later date. In England the abundance of water power and coal the proximity of major ports, the humid climate and the extensive existing domestic industry all favoured the location of the new factory industry in Lancashire, and in the course of the 19th century the other centres of the industry—west Scotland, Derbyshire and Nottinghamshire—declined relatively in importance. By 1900 well over 80% of the operatives employed in the industry were in Lancashire and adjacent Cheshire.

The enormous increase in the productivity of labour as a result of the revolution in techniques greatly reduced production costs, and this in turn led to a tremendous expansion in the market for cotton goods all over the world. The demand was satisfied partly by exports, which were supplied to an overwhelming extent by Great Britain, and partly by the spread of the industry itself. The first mills in the United States were established late in the 18th century and others were established about the same time on the continent of Europe, most of them being protected by a high import tax. Until the mid-19th century the mill industry was virtually confined to Europe and North America; afterward began the wider diffusion that has continued ever since and has brought so many problems to the longer-established industries. The cotton industry has always been one of the first to be established in newly industrialized countries, since it does not present great technical difficulties and does not require large amounts of capital. The foundations of the Indian mill industry in Bombay date from the 1850s. The Japanese cotton industry began about 1870 although it did not really flourish for another 20 years. Before World War I extensive industries had also developed in China, Brazil, Mexico and Canada.

The spread of the industry across the world was paralleled by an equally remarkable territorial shift within the United States. The original location of the industry was New England, but after the Civil War a combination of lower wages and the financial inducements granted by state governments attracted more and more mills to the cotton-growing states, particularly the Carolinas, Georgia and Alabama. In 1908 about 51% of the raw cotton consumed in U.S. mills was manufactured in the cotton-growing states, as compared with only 15% in 1880. The trend continued later in the 20th century. By the early 1960s about 95% of all raw cotton processed in the U.S. was manufactured in the cotton-growing states; the amount manufactured in New England was only about one-eighth of the amount processed there in the peak year of 1916.

The development of the industry up to 1914 is demonstrated by a few figures. In 1790 mill consumption of raw cotton totaled about 25,000,000 lb. (It has been estimated that hand spinning and other consumption may have amounted to about 500,000,000 lb. a year at that date.) In the years immediately before World War I mill consumption of cotton throughout the world averaged about 10,500,000,000 lb. a year. Consumption outside Europe and North America accounted for about 20% of this total, as compared with only about 5% in the early 1880s.

The Lancashire cotton industry expanded until 1914 (although the rate of growth slowed down considerably after about 1860) but by 1910-13 Lancashire's share of total world mill consumption was down to about 20% and it had been surpassed by the United States in volume of production. Even in the export field its supremacy was challenged. Although Lancashire's exports of cotton piece goods continued to expand, reaching more than 7,000,000,000 yd. in 1913, exports from continental European countries and the United States were expanding much more rapidly, and Japan had also begun to compete. As a result the U.K. share of total international trade in cotton yarn and manufactures fell from about 82% in 1882-84 to 58% in 1910-13, when more than four-fifths of Lancashire's production was being exported. Between 1910 and 1913 the U.S. exported about 4% of its cotton goods; this amount accounted for 3% of the world trade.

It is doubtful whether any other industry in modern times has so dominated international trade and at the same time been so dependent on it as the Lancashire cotton industry. It was a unique achievement—and left Lancashire uniquely vulnerable.

**2. Development After 1914.**—Mill consumption of raw cotton more than doubled in the half century after 1910; this increase compares with an estimated population increase over the same period of rather more than 60%. The difference between the two rates reflects rising standards of living and becomes even more remarkable when it is recalled that the man-made fibre industry developed in this period. World consumption of man-made fibres, which compete directly with cotton in a large number of uses, equaled about 30% of the world consumption of cotton in the 1960s.

**Distribution of the Industry.**—After 1910 a continued dispersion occurred in the industry. The interruption of supplies during 1914-18 stimulated the expansion of the industry in India, China and Japan, while between World Wars I and II the Indian industry continued to expand, under the protection of tariff barriers, and the Japanese industry initiated a rapidly growing export trade. After the great depression of the early 1930s industrialization proceeded and, with the help of protective tariffs, cotton industries were established or expanded in many countries. World War II boosted this process, leading to a considerable expansion of the industry in Latin America, Egypt, Turkey, South Africa, Australia and elsewhere. After 1945 the industry was established or greatly expanded in South Korea, Formosa, Israel, the Philippines and Nigeria, among other countries. Spinning mills were built in Hong Kong from 1948 onward with refugee Chinese capital; the growth of the industry there was phenomenal and Hong Kong became a major exporter. The partition of the Indian subcontinent left almost all the cotton mills in India but a very important part of the cotton-growing area in Pakistan. The latter country embarked on a rapid development of its industry, becoming more or less

self-sufficient by 1957 and entering the export field on a big scale. Cotton manufacturing developed rapidly in the Communist countries, particularly China. The Japanese industry, after being virtually destroyed during World War II, expanded strongly afterward, although by 1961 it had not regained its prewar size because of the shrinkage in world trade, increased competition in the international field and the substitution of man-made fibres. Consumption in the United States increased rapidly until after the war and then from 1951 showed a slight tendency to decline on account of decreasing exports and increasing imports. As a result of all these changes consumption outside Europe (including the U.S.S.R.) and North America amounted by 1957-59 to about 45% of total world consumption, as compared with about 20% before World War I. In the early 1960s there was no sign of a halt in the spread of the industry, since important developments were under way in many countries, including Indonesia, Ceylon, the Sudan and Ethiopia.

**World Trade in Cotton Piece Goods.**—World exports of cotton piece goods expanded up to 1910-13, but the growth of the Indian and Chinese industries during World War I led to a reduction in trade. This decline accelerated after the great depression of the early 1930s as more and more countries began to manufacture cotton goods and to tax cotton imports. Despite the world trade decline, Japan managed to increase its exports of cotton goods very rapidly because of cheap labour and efficient production methods; by the late 1930s Japan was easily the largest exporter of cotton piece goods, accounting for slightly more than 40% of the total world trade. The combination of a declining total trade and an increasing Japanese share naturally struck hard at the other exporting countries—the U.S., Europe and above all the U.K. The expansion of domestic industries in importing countries during and immediately after World War II led to another fall in world trade. By then India was a major exporter and the U.S. had also greatly increased its exports, mainly to Canada and Latin America, taking some 14% of the world trade in 1949-51 against 3.5% in 1936-38. After World War II the losers were Japan and, once again, the U.K.; in both countries, it was inability to expand production quickly enough after wartime contraction that held exports down.

The period of postwar reconstruction ended about 1951. Thereafter world trade in cotton piece goods did not decline any further and by the end of the 1950s it even appeared to be expanding. Japan re-emerged in 1949-51 as the principal exporting country and was still expanding its exports by 1960, though its share of total world trade—about 23%—was considerably smaller than before the war. After a period of decline western European exports increased in 1958-60; this increase was mainly in intra-European trade, stimulated by the Common Market. Exports from the U.K. fell very sharply after 1949-51 and exports from the U.S. declined almost as sharply. A considerable number of other countries became exporters, particularly Hong Kong, Pakistan (mainly in the yarn trade), Egypt, Formosa, South Korea, Yugoslavia and Canada. There was also a big expansion in exports from Communist countries, particularly China.

World trade in cotton textiles by 1960 amounted to about 10% of world production, as compared with about 16% in 1936-38 and about 28% in 1910-13. Imports were largely concentrated in two groups of countries: first, countries that were not self-sufficient in cotton textiles, notably the continent of Africa, parts of Asia (particularly Indonesia) and Latin America, Scandinavia, Canada, Australia and New Zealand; secondly, the exporting countries of Europe and the U.S. The imports into the western European countries mostly came from other European countries, while the imports into the U.K. and U.S. mostly originated in Asia. It was the imports into the U.S., U.K. and western Europe that were tending to expand.

**The Cotton Industry in the United Kingdom.**—Immediately before World War I four-fifths of U.K. production was for export, and about 40% of the exports went to India. The expansion of the cotton industries in India, China and other countries and formidable competition from Japan for the trade that remained reduced U.K. exports from an annual average of 6,550,000,000 sq.yd.

in 1910-13 to 1,720,000,000 sq.yd. in 1936-38. Over the same period the average annual consumption of raw cotton in the U.K. declined by 37% and cloth production fell by about 54%. It has been estimated that Lancashire's losses in the Indian market alone were sufficient to account for a contraction of one-third in its cotton-cloth output between 1912 and 1938. As a result, the interwar years were ones of chronic depression, characterized by the closing of mills, heavy unemployment and cutthroat competition. During World War II the industry suffered compulsory contraction, and during the postwar period recovery was limited by shortages of labour. Even in the peak postwar year, 1951, production (including man-made fibres processed in the cotton industry) was no more than about three-quarters of the 1937 level. After 1951 exports of cotton piece goods began to fall, and in 1961 they were still declining. In 1958-60 they averaged only 350,000,000 sq.yd. per annum, as compared with 860,000,000 sq.yd. in 1949-51. The proportion of world trade in cotton piece goods accounted for by the U.K. in 1958-60 was only just over 6% and a large proportion of these exports consisted of cloth that had been imported in the gray state and merely finished in the U.K. before being re-exported. In 1954 India began to export goods intended for consumption in the U.K., not for re-export, and was soon joined by Hong Kong and later by Pakistan, all of them taking advantage of the fact that commonwealth goods were allowed to enter the U.K. duty-free. These imports continued to expand and, coupled with the decline in exports, led to a further substantial contraction in the output of the U.K. industry. From the end of 1954 to well into 1959 there was a great deal of short-time work (less than full capacity), with only a comparatively brief respite in 1957; although many mills closed down, a vast amount of surplus capacity remained.

Many efforts were made by the U.K. cotton industry to secure some limitation of duty-free imports from the commonwealth, and in 1959 the government introduced reorganization schemes in an attempt to put the industry back on its feet. Mill owners were offered compensation for scrapping machinery or going out of business entirely, two-thirds of the cost to be met by the government and one-third by means of levies on firms remaining in the industry. The government also offered to pay one-quarter of the cost of approved schemes of modernization. Under the first provision, almost half the spinning capacity of the industry and about 40% of the looms were scrapped. This, coinciding with a world-wide boom, brought a flood of orders to the remaining mills and full-time work was the rule, with some exceptions, until 1961. However, a shortage of labour again made it impossible to take full advantage of the opportunity and the gap was filled by imports, partly speculative, from nonrestricted sources, notably Spain but also Portugal, Yugoslavia, Formosa, the U.S. and Canada. In the early 1960s imports of cotton cloth were entering at a rate equivalent to about one-third of total home consumption and the U.K. was then the largest importer of cotton cloth in the world. Mill consumption of cotton in the U.K. was less than half what it was before World War II and only about 30% of the level before World War I; it accounted for only slightly more than 3% of total world mill consumption.

**The Cotton Industry in the United States.**—The consumption of cotton by United States mills expanded very rapidly during World War I. The wartime rate of use was not maintained during the immediate postwar years, but a new peak was established in the years 1926-28. The great depression caused another setback, and by 1936-38 the recovery in cotton consumption had hardly done more than equal the previous peak. The main reason was that exports of cotton textiles, though never very important to the U.S. industry, had fallen quite sharply. Throughout this period the New England section of the cotton industry had been contracting severely, causing great distress to those communities heavily dependent on the industry. World War II caused another great expansion in the U.S. cotton industry, and after a decline in the immediate postwar years the Korean war brought another boom. Cotton consumption in 1951, however, was not quite as great as in the peak World War II years. After 1951 cotton consumption in the U.S. declined gradually. One reason for the

decline was that exports of cotton cloth, which expanded rapidly during World War II and reached 1,490,000,000 sq.yd. in 1947, subsequently declined steadily until in 1960 they amounted to no more than 440,000,000 sq.yd. The second main reason was that from 1953 onward imports of cotton goods from Japan began to increase rapidly, re-establishing a trade that had been important before the war. In 1955 the Japanese cotton industry was persuaded, under pressure, to put a voluntary ceiling on its exports to the U.S. In 1959 and 1960 imports began to flood in from a number of other countries, notably from Hong Kong but also from India, Pakistan, South Korea, Formosa, Egypt, Spain, Portugal and France. In 1960 U.S. imports of cotton products from all sources were equivalent to about 6% by weight of total U.S. home-market consumption. In 1961 a request from the U.S. government to the Hong Kong industry for a ceiling on exports similar to the Japanese undertaking was turned down. The U.S. cotton industry suffers a special handicap in that American raw cotton is sold to foreign mills considerably more cheaply than it is to domestic mills.

**World Problems.**—On a world scale, the most intractable problem facing the industry in the early 1960s was undoubtedly that of competition between low-wage and high-wage countries since wages account for a relatively high proportion of the cost of yarn and cloth. Since about 1954 the battle has been extended from third markets to the home markets of the high-wage exporting countries themselves, notably the U.K. and the U.S. There have been two principal methods of dealing with the problem: (1) quotas imposed by importing countries and (2) voluntary restrictions undertaken by exporting countries. Quotas were imposed on imports of cotton goods from China by almost all western countries, on imports from Japan by most European countries (including the U.K., France, western Germany, the Netherlands, Belgium and Austria) and on imports from India, Pakistan and Hong Kong by a few European countries; but a wider use of the quota weapon has generally been felt undesirable in view of the trend toward more liberal trade policies. Examples of the second method are the voluntary ceilings placed by the Japanese on their exports to the U.S., Canada, Denmark and Switzerland and similar undertakings of the Indian, Pakistan and Hong Kong industries in respect of their exports to the U.K.

**3. Machinery.**—In spite of the steady increase in the quantity of cotton consumed by the world's cotton mills there has been a decrease in the amount of machinery installed. Figures published in *International Cotton Industry Statistics* by the International Federation of Cotton and Allied Textile Industries show that the total number of spinning spindles in place reached a peak of 165,000,000 in 1928, subsequently declining to 148,000,000 in 1939. After wartime destruction and postwar reconstruction the figure in the early 1960s was about 130,000,000. Most of this decline can be attributed to the replacement of the less-productive mule spindle by the ring spindle. The number of mule spindles declined from 71,000,000 in 1913 to 3,000,000 in 1959. The number of "ring-equivalent" spindles in place (reckoning one ring spindle as being equivalent to one-and-a-half mule spindles) reached a peak of about 145,000,000 in 1930, declined to 135,000,000 in 1939 and totaled about 127,000,000 at the end of 1959. The International federation's first world-wide census of cotton power looms in 1930 recorded 3,159,000 in place. The total had fallen to 3,070,000 in 1936 and to 2,633,000 in 1959. The proportion of automatic looms increased from 23% in 1930 to 41% in 1959. The disparity between the decreasing amount of machinery in place and the increasing consumption of cotton is explained by the increased speed of the machinery and, more important, the considerable increase in the number of operating hours, since shift working became the rule rather than the exception. The decline in the amount of machinery has been concentrated in the U.K., the rest of Europe (excluding the U.S.S.R.) and the U.S. In other parts of the world, particularly Asia, capacity has increased.

**4. The Uses of Cotton.**—According to estimates made by the Food and Agriculture organization of the United Nations, the average consumption of cotton per person throughout the world

was about  $7\frac{1}{2}$  lb. a year in 1956-58 (Commodity Bulletin Series, 31). This global average, however, concealed a vast difference between the consumption per person in different countries. At the top of the list came the U.S. with an annual consumption per person of about 23 lb. Next came a group consisting of the north-western European countries, Canada, Australia, New Zealand, Argentina, Israel, Japan, the U.S.S.R., the German Democratic Republic and Czechoslovakia, with averages between 10 lb. and 15 lb. a year. In contrast, average consumption in the whole of the African continent was only about  $2\frac{1}{2}$  lb. a year, and in large parts of that continent, and also in some Asian and South American countries, it was lower still.

The overwhelming bulk of the world's cotton, except for small amounts used for hand spinning and for such other uses as stuffing mattresses, is consumed in spinning mills. In the U.K., for example, only about 1% of the total is used for other purposes; e.g., wadding and cotton wool. By far the greater proportion of cotton yarn (about 80% in the U.K. and the U.S.) is manufactured into broad-woven cloth composed wholly of cotton or of cotton mixed with other fibres (particularly the man-made ones); these other fibres are woven with the cotton yarn or are blended with it at the spinning stage. The remainder of the yarn is used for knitwear, thread, ribbons, ropes, nets, lace, carpets and other purposes. The broad-woven cloth is woven either of gray or of bleached or dyed yarn and usually has to be finished in some way; e.g., bleached, dyed, printed, shrunk and made crease resistant. It may, however, be virtually ready for use in the loom state without finishing. Examples of this are gray cloth used in industry and yarn-dyed cloth used for curtains or upholstery.

Cotton products are divided conventionally into three main categories according to their use. First there is apparel, including linings. Then there are the household goods such as sheets, towels, curtains, upholstery and also domestic sewing thread. The third main category is usually referred to as industrial uses. This includes the use of cotton in manufacturing equipment—for example, factory belting and filter cloths, and also uses in which the cotton forms part of an article, e.g., tire cord, car upholstery, book cloth and electrical insulation. In the U.S. just over half of the cotton consumed is used for apparel, slightly more than one-quarter for household uses and about one-fifth for industrial uses. In France the corresponding proportions are rather over a half, rather less than one-quarter and about one-quarter respectively. In the U.K., as far as it is possible to judge, the proportion used in apparel seems to be less than in the U.S. and France, and the proportion consumed in both household and industrial uses seems to be greater than in either of those countries. In the newly emerging countries, of course, almost all the cotton is used for apparel.

**5. Organization of the Industry.**—When the power loom was first generally adopted, the normal method of organization in Lancashire was for spinning and weaving to be carried on in the same establishment. There are, however, certain economic advantages in separating the two processes, and spinning and weaving in Lancashire came to be carried on in separate mills and by separate firms. There was even a geographical separation of a minor sort in that spinning became concentrated in the south and weaving in the north of the Lancashire cotton region. At the same time, the overwhelming importance of the export trade favoured a separation of weaving from styling, and a large class of merchant converters grew up, many of whom specialized in exporting to particular markets. Thus the classic Lancashire form of organization developed: the spinner sells the yarn to the weaver, and the weaver then sells the gray cloth to a converter, who has it bleached, dyed or printed on commission by a specialist finisher. The converter then sells the finished cloth abroad or to a wholesaler, garmentmaker or other user in the U.K. Because of technical developments and the decline in the export trade, the traditional structure of the Lancashire industry was not well suited to modern conditions, and after World War II there was a distinct trend toward more vertical integration, with the result that spinners and weavers gained greater control over the distribution of their products.

The structure of the U.S. cotton industry is very different. Spinning and weaving have always been integrated to a very large extent, not only in the same companies but in the same mills, which often have long runs on a few standardized products. The main reasons for this are the size and comparatively low density of the population; the fact that selling was concentrated in a comparatively small number of sales agents, who could instruct the mills they represented to concentrate on particular constructions; and finally the growth of the large multi-unit concerns, which also could order concentration of production of certain cotton goods in the mills they owned. In the past, spinning and weaving were largely separated from converting. Before World War II there was a movement on the part of mills, particularly those in the household textiles field, to finish, make up and sell their goods as branded products in order to secure outlets for their productions. At the same time, users of industrial textiles (tire manufacturers, surgical dressing manufacturers, bag manufacturers, etc.) were buying mills in order to control the quality of their supplies. The trend toward vertical integration accelerated during and immediately after World War II as mills began to convert their cloth in order to secure additional profits at a time when prices were controlled and selling was easy, and as converters acquired mills in order to assure themselves of supplies of cloth. In the early 1960s the majority of U.S. mills converted their own fabrics, usually in their own finishing plant.

The European industries tend to fall between the extremes of the U.K. and the U.S. in point of structure. There is a good deal more vertical integration than in Lancashire, including integration with finishing, but less than in the U.S. The Japanese industry is dominated by the integrated spinner-weavers who produce mainly for export, but a large number of independent weavers are supplied with yarn by specialist spinners and from the surplus yarn production of the spinner-weavers. Many of these "independent" weavers, however, merely weave on commission for spinners or merchants. The large spinner-weavers convert their own fabrics, usually in their own finishing plants, but the selling and distribution is left entirely to merchants. The Hong Kong industry is in many respects similar to the Japanese industry; e.g., it has a strongly integrated sector directed mainly to the export trade and flanked by specialist spinners and weavers. In India, power-loom weaving is integrated almost completely with spinning. There is also an important Indian hand-loom industry that is protected by government policy against competition from the mills; it is supplied with yarn mainly by specialist spinning mills but also from the surplus yarn production of integrated mills. The structure of the Pakistan cotton industry is in many respects similar to that of the Indian industry and also includes an important hand-loom sector.

There are numerous other points of contrast between the various cotton industries of the world. As regards machinery, for example, Britain was virtually the only country in 1961 in which mule spinning survived; even there, however, there were fewer than 3,000,000 mule spindles, as compared with 23,000,000 in 1945 and 45,000,000 before World War I. In weaving, automatic looms were practically universal in the U.S. and Canada, the high wage level being an overwhelming incentive to labour-saving methods. In the U.K. less than 30% of the looms were automatic—a smaller proportion than in almost any other important western European cotton industry. The proportion of automatic looms in India was among the lowest in the world, mainly because of government restrictions on the mill sector of the industry, and even in Japan it was only just over one-sixth; in Japan, however, the vast majority of the looms owned by the integrated spinner-weavers were automatic.

Lancashire has for long had the melancholy distinction of working its machinery for fewer hours during the year than any other industry. Until the 1959 reorganization schemes, single-shift working was almost universal in spinning and largely predominant in weaving, but the scrapping of so much machinery made an appreciable difference. In the 1960s double-shift and three-shift work schedules were fairly widespread, particularly in weaving. In contrast, three-shift working was practically universal in the U.S. and in the spinning and integrated spinning-weaving mills in Hong

Kong. Double-shift working was the rule in the Japanese spinning and integrated mills, and in all other cotton industries two- and three-shift working was far more common than in Lancashire.

In the early 1960s more than 60% of the employees in the U.K. cotton industry were female, many of them married women. The proportion of women in the Japanese industry was even higher—more than 80%—but they were almost all young girls who were working for a few years before marriage and living in dormitories attached to the mill. The percentages of women in western European cotton industries varied greatly, ranging from about 80% in Italy to less than 20% in the Netherlands. There were more men than women workers in the United States and Hong Kong industries, and in India 94% of the labour force were men.

**COTTONMOUTH**, a venomous snake native to North America and also called cottonmouth moccasin or water moccasin. See MOCCASIN.

**COTTON RAT**, one of several species of American rodents of the genus *Sigmodon*, occurring from the southern United States into South America. The commonest, *S. hispidus*, the hispid cotton rat, is typically ratlike in appearance. It measures 10 to 14 in., about one-third of that length being a thin, scaly, sparsely haired tail. The colour is a grizzled blackish brown. Cotton rats are exceedingly prolific, producing several litters of two to ten young each year. Where they occur, they are likely to be numerous and the dominant small mammal. The habitat is varied, but a preference is shown for weedy fence rows and ditch banks. The nest, in a shallow runway or tunnel, is constructed of any available fibrous material. Cotton rats are aggressive and pugnacious. They eat virtually anything edible and often become serious agricultural pests. They do not climb, hibernate or store food.

(K. R. KN.)

**COTTONSEED.** Cottonseed is obtained as a by-product of cotton production. For each pound of fibre, cotton plants yield approximately two pounds of seed. The commercial importance of cottonseed lies in the four principal products obtained through processing—oil, cake or meal, linters and hulls.

**History.**—Although cotton fibre has been a product of commerce for centuries, large-scale commercial utilization of cottonseed is a comparatively recent development. In ancient times the Chinese and Hindus used cottonseed oil as a medicine and in lamps and developed crude methods for its recovery, but it was not until the production of cotton began its rapid increase following the invention of the cotton gin in 1794 that systematic and continuing efforts were made to develop machinery for the commercial processing of cottonseed. Even as late as 1875 the principal use of cottonseed was for planting purposes, while the remainder over and above these requirements was regarded mainly as a waste product that frequently was disposed of by burning or dumping into streams near the cotton gins. This practice created a serious health problem, and several states passed laws making it a punishable offense to accumulate seeds around gins to the detriment of the health of the nearby inhabitants, or to dump cottonseed into streams used for drinking water or fishing.

The history of the development of the cottonseed industry is almost wholly a history of the development of the industry in the

United States. In the 18th century various individuals and organizations recognized the potential value of cottonseed as a source of oil and other products and urged producers to develop feasible methods for obtaining these products. Among the first was Bodo Otto of Pennsylvania, who in 1768 presented the American Philosophical society with samples of oil he had obtained from cottonseed. In 1783 the Society for the Encouragement of Arts, Manufactures and Commerce in England offered a gold medal to any planter in the West Indies who was able to express one ton of oil and produce 500 lb. of cake from cottonseed. Two years later a premium was offered by the South Carolina Agricultural society in an effort to encourage the expressing of oil from cottonseed. (There is no record that either of these awards was ever claimed.)

Between 1800 and 1825 several cottonseed-oil mills were built in various parts of the U.S. south, but they were all financial failures and none of them was very long in operation. The first mill that could be called successful was established in Natchez, Miss., about 1833 and operated for nearly ten years.

Beginning about 1850 a number of improvements were made in cottonseed processing machinery that led to a more successful operation of the mills. By 1860 there were seven active mills crushing a total of approximately 50,000 tons of seed annually. Progress was stopped by the Civil War, but in the years following the war the industry again began to expand. By 1870 there were 26 active mills and by 1930 about 850 mills.

In 1876 only 5% of the cottonseed crop was crushed for oil and other products, but after 1910, 80% of the crop reached the oil mills. No cottonseed is now wasted. Cottonseed that is not crushed remains on the farms and is used for planting, as fertilizer for crops and as farm feed.

World production of cottonseed in the early 1960s was over 20,000,000 tons. The United States, India, China, Mexico, Egypt and Brazil provided more than half the world supply. The United States produced about 6,000,000 tons annually.

**Processing.**—Processing consists essentially of (1) cleaning; (2) removing the fuzz or linters; (3) hulling; (4) flaking and cooking the kernels; and (5) recovering the oil by pressing or by solvent extraction. The residue remaining after oil removal is cottonseed cake, which is usually ground and marketed as meal.

Cottonseed is cleaned by means of a variety of devices to remove foreign substances, and passed through delinterring machines to remove the short fibres. These machines are similar to cotton gins but have circular saws with much finer teeth. Linters are removed by successive cuts known as first, second, third and fourth cuts. Each type has different uses (see below).

The delinterring seed are hulled and the kernels separated from the hulls. The kernels are flaked and cooked to facilitate maximum oil recovery; they are passed between steel rollers to flake them to a thickness of about .007 in. The flakes are tempered with moisture and heated in steam-jacketed cookers equipped with mechanical agitators to a temperature of about 235° F. for 30 to 90 minutes.

For many years hydraulic pressing was the only method used for recovering oil from the prepared flakes. In this method the flakes are formed into cake, wrapped in thick haircloth and pressed in a hydraulic press. For some markets the pressed cake is broken and sold as cottonseed cake, but most of it is ground and sold as meal.

A later process used by many oil mills is the continuous screw-pressing method. The flaked kernels are conditioned as for hydraulic pressing and fed into a slotted cage made up of steel bars set a few thousandths of an inch apart. A revolving screw carries them along inside the cage or barrel. The screw is so designed that high pressures and temperatures are developed. The oil flows out through the openings between the bars and the cake is discharged at the end of the barrel.

Solvent extraction is now used to some extent for commercial processing of cottonseed. The kernels are prepared in a manner similar to that for hydraulic pressing and then extracted with commercial hexane, a petroleum solvent. The solvent is recovered by distillation from both the oil and the extracted flakes for reuse. In some mills a prepress-solvent extraction process is used in which

the flakes are screw pressed at low pressures and the residual oil in the pressed cake removed subsequently by extraction with commercial hexane.

As oil is the most valuable product obtained from cottonseed, the trend has been toward the use of the newer processes for its recovery. Although both hydraulic pressing and screw pressing produce oil of acceptable quality, both processes leave from 3.5% to 7% of oil in the cake. The processes using solvent extraction reduce the oil content of the meal to less than 1%. The newer plants are generally of large capacity, processing up to 900 tons of cottonseed a day or more. The estimated annual average world production of cottonseed oil is more than 5,000,000,000 lb. This is about 23% of the production of edible oils and 7.5% of the production of fats and oils from vegetable, animal and marine sources.

Crude cottonseed oil is generally dark in colour and contains many constituents that must be removed before the oil can be used for food purposes. Removal is accomplished by filtration, refining, bleaching and deodorizing. The filtered crude oil is refined by treatment with solutions of sodium hydroxide and other alkaline compounds that combine with the free fatty acids forming soap and remove nonglyceridic materials. For many years the standard practice was to use large, conical kettles for refining. The alkali solution reacted with the free fatty acids is separated by settling to form soap stock. The oil is drawn off and water washed to remove remaining soap particles. Continuous centrifugal refining is now generally used in the United States. In this process the crude oil is intimately mixed with the proper proportion of alkali solution and the separation of soap stock is accomplished by use of a high-speed centrifuge. The oil is then treated by washing and drying to remove the last traces of soap and water.

When the oil is to be used as a salad or cooking oil, it is further purified by bleaching, "winterizing" and deodorizing. Bleaching is done by mixing bleaching agents with the refined oil and removing them by use of filter presses. The bleaching agents used are fuller's earth (*q.v.*) and acid-activated bleaching clays. The latter are sometimes used in combination with activated charcoal. These materials absorb colouring substances. The refined oil is "winterized" to remove the saturated glycerides so that the oil will be liquid at usual refrigeration temperatures. This is done commercially by chilling the refined oil, allowing the solidified portion to settle and separating the clear oil by decantation and filtration. Deodorizing is accomplished by vacuum distillation of the heated oil to remove odoriferous materials by both batch and continuous processes.

The most important uses for cottonseed oil are in shortening and margarine or plastic fat products. For these purposes the oil is further processed by hydrogenation to produce a fat product with any desired melting point up to about 140° F. The unsaturated fatty acids (oleic and linoleic) are in part converted to saturated stearic acid in this process by passing hydrogen gas into the oil in the presence of a nickel catalyst. The properties of the hardened oil are varied by control of processing methods to give specialty shortenings for the prepared food industries.

Acidulated soap stock is obtained by heating raw soap stock (foots) with an excess of sulfuric or other mineral acid in a corrosion-resistant vat until the soap is decomposed. After settling, a layer consisting of fatty acids and neutral oil forms on top and is decanted from the aqueous layer.

Fatty acids are obtained by distillation of acidulated soap stock for use by the soap and chemical industries. The feed industries in the United States are now using increasing quantities of acidulated soap stocks and inedible fats to increase the energy value of mixed feeds. The residue after distillation of the fatty acids is the fatty acid pitch of commerce.

**Utilization of Cottonseed Products.**—Although cottonseed products have been used variously for centuries, their greatest commercial utilization has been in the United States. The commercial processing of cottonseed has been increased in other countries, principally Mexico, Brazil, India and Egypt. The yield of products is influenced by the variety of cotton, the environment under which the cotton crop is grown and the efficiency of the processing

methods used for recovery of the oil. Typical average yields per short ton of seed crushed are: 314 lb. of crude oil; 901 lb. of cake or meal; 466 lb. of hulls; 184 lb. of linters; and 135 lb. of processing waste and loss.

**Oil.**—Thoroughly refined and processed cottonseed oil is one of the principal high-grade edible oils of commerce. The average factory consumption in the United States of refined cottonseed oil is approximately 30% of the total of all edible and inedible vegetable oils used annually. About 29% of the refined cottonseed oil consumed annually goes into the manufacture of margarine; 35% into shortenings; 30% into salad oil, salad dressing, mayonnaise, cooking oils and other products; and 2% into inedible products. "Winterized" cottonseed is a superior salad and cooking oil because of its good keeping quality. About 75% of the "winterized" vegetable oils are obtained from cottonseed oil. Owing to studies of the relation of fats to health there has been a trend toward increased use of salad and cooking oils and decreased use of shortening.

The use of cottonseed oil in inedible products is limited largely to off-grade oils and soap stocks. The oil and fatty acids obtained from them and acidulated soap stocks are used in the manufacture of soaps, lubricants, protective coatings and chemical products. The fatty acid pitch is used chiefly in the production of floor coverings, composition roofing and insulating materials.

**Cake and Meal.**—Cake and meal are used principally as high-protein supplements in feeding cattle. They contain up to 45% protein as usually produced. The annual production provides between 25% and 30% of the supply of high-protein feeds in the United States. Methods of processing were developed to reduce the influence of gossypol, a pigment peculiar to the cotton plant, to a low level, with the result that cottonseed meal can and has been used in mixed rations for single-stomached animals (swine and poultry). Cottonseed meal also is used to some extent as a fertilizer, and small quantities are used in making starch-free flour for human consumption.

**Hulls.**—The hulls are used as roughage for feeding beef and dairy cattle. Considerable quantities are ground and incorporated in mixed feeds. They are rich in pentosans and are potentially a source of material for the commercial production of furfural, an important industrial chemical.

**Linters.**—Linters are the short fibres left on the seed after removal of the staple cotton fibre by ginning. They are largely cellulose and are transformed into many useful products. First-cut linters are used in making high-quality mattresses and in the manufacture of coarse cotton yarns.

Some quantities of linters are used in the production of high-quality writing paper. Second- and subsequent-cut linters, after mechanical and chemical purification, are used in the manufacture of explosives, cellulose acetate, rayon, plastics, ethyl cellulose, lacquers, sausage casings and many other cellulose products requiring high-quality cellulose as a raw material. In many of these end uses linters compete with wood cellulose, rubber and synthetic products.

**COTTONTAIL**, the common name in the U.S. for several species of rabbit (*q.v.*) of the new world genus *Sylvilagus*. Cottontails are grayish to dark brown in colour, lighter below, with a whitish tuft under the tail. See also HARE.

**COTTONWOOD:** see POPLAR.

**COTTRELL, FREDERICK GARDNER** (1877–1948), U.S. teacher, scientist, inventor of the Cottrell electrostatic smoke (fume) precipitator and founder of Research corporation, a non-profit foundation to support basic research in colleges and universities, was born in Oakland, Calif., on Jan. 10, 1877. Educated in chemistry at the University of California, Berkeley, with post-graduate work in Germany under Liebig and Ostwald, he was instructor of physical chemistry at the university, 1902–06, and assistant professor, 1906–11. Retained by local industry in the San Francisco bay region to combat air pollution, Cottrell began his successful work on electrostatic precipitation in 1906, turning over the basic patents he was granted to Research corporation, administered by the Smithsonian institution. By the second half

of the 20th century the corporation had contributed more than \$21,000,000 in grants for research and eight grantees had received the Nobel prize for their work. Cottrell thus gave up a large personal fortune and lived and died in moderate circumstances, but his outgoing personality and his catholicity of scientific interests sparked the success of thousands of younger men.

Serving with the U.S. bureau of mines, 1911–20, he developed and administered the process of separating helium from natural gas, led in the development of the bureau's mine safety division and served as director of the bureau (1920). He also served with the U.S. department of agriculture (1922–43), specializing in fixed nitrogen research. He died in Berkeley on Nov. 16, 1948.

See also PRECIPITATION, ELECTROSTATIC.

See Frank Cameron, *Cottrell, Samaritan of Science* (1952).

(JH. W. B.)

**COTY, FRANÇOIS** (FRANÇOIS MARIE JOSEPH SPOTURNO) (1874–1934), French perfume manufacturer and newspaper owner, was born in Ajaccio, Corsica, on May 3, 1874. He started his career as secretary to the Corsican deputy and journalist Emmanuel Arene. Attracted toward the chemistry of perfumes, he started a small business and from 1900 evolved perfumes that were highly successful. In 1905 he opened a plant at Suresnes, near Paris, and during the years of World War I became one of the richest men in France, though in later years his wealth was much reduced.

Prompted by political ambitions and by concern at the social disorganization after the war, he gained control in 1922 of the conservative Paris daily paper *Le Figaro*, of which he was proprietor and director from 1924 until 1932, using it to advocate a strong nationalistic policy. To carry his message to the masses in an effort to check the growth of socialism and communism in France, he founded in 1928 *L'Ami du Peuple* and *L'Ami du Peuple du Soir*. Both were subsidized by the scent business and sold at half the price of other daily papers, which assured them a wide circulation. He also founded La Solidarité Française, an organization aimed at furthering his political and social ideas. Coty died at Louveciennes, Seine-et-Oise, on July 25, 1934.

**COTY, RENE** (1882–1962), last president of the fourth French republic, was born at Le Havre (Seine-Maritime) on March 20, 1882. A graduate of the University of Caen, he became a barrister and soon entered local politics. From 1923 to 1935 he served as a deputy of the Gauche Républicaine (a label which implied conservatism) and then became a senator. In Dec. 1930 he was undersecretary of state for the interior for a few weeks.

Politically inactive during the German occupation, Coty after World War II was again a deputy (1945–48) and a senator (1948–54). He was minister of reconstruction from Nov. 1947 to Sept. 1948 and a vice-president of the senate from Jan. 1949. Respected for his courtesy and his spirit of conciliation, he was induced to become a candidate for the presidency in Dec. 1953, when the election seemed likely to produce a deadlock. He was elected on Dec. 23 on the 13th ballot.

Coty served with dignity, but was less active in trying to influence policy than his predecessor, Vincent Auriol, had been. In the crisis of May 1958 his threat to resign helped to induce the national assembly to elect Gen. Charles de Gaulle as prime minister. He retired on Jan. 8, 1959, when De Gaulle was installed as the first president of the fifth republic. Coty died at Le Havre on Nov. 22, 1962.

(P. W. C.)

**COTYLEDON**, the first leaf or leaves of the embryo in seed plants, also called seed leaf. In most plants the cotyledons are elongate, thin, and leaflike, functioning as organs of digestion of food stored in endospermous tissue of the seed; these expand upon germination of the seed into photosynthetic organs. In other cases cotyledons may be stout, fleshy storage organs that have absorbed the endosperm before maturation of the seed; these rarely become leaflike upon seed germination.

The number of cotyledons is constant and provides one of the characters for the primary division of angiospermous or flowering plants into Monocotyledonae with one seed leaf (for example, lilies, orchids, palms, grasses) and Dicotyledonae with two seed leaves (majority of plants). In the embryos of gymnospermous

plants, as for example the pines, there are more than two cotyledons arrayed in a whorl that surrounds the shoot apex. (See ANGIOSPERMS; SEED.)

*Cotyledon* is also the generic name for a group of succulent plants of the Old World; they are native mostly to South Africa and the Mediterranean region and belong to the orpine or stonecrop family (Crassulaceae; *q.v.*).

**COTYS** (ΚΟΤΥΣ), a Thracian goddess worshiped with orgiastic rites, especially at night. Her worship, first mentioned by Aeschylus, was apparently adopted publicly in Corinth by the last quarter of the 5th century B.C., and perhaps privately in Athens; it then included a baptismal ceremony. Later relief sculptures from Thrace show her as a huntress-goddess similar to Artemis. But in literature she is rather compared with Cybele, and her cult is synonymous with immoral practices. This aspect can be linked with some rites to Artemis as practised among the Dorians.

See W. Roscher, *Lexikon* (1924); M. P. Nilsson, *Geschichte der griechischen Religion*, vol. 1, p. 835, 2nd ed. (1955). (H. W. PA.)

**COUCY** (now part of Coucy-le-Château-Auffrique in the département of Aisne), a small town of northern France, 18 mi. W.S.W. of Laon, important in the middle ages both for its castle and for the family of the sires de Coucy. A commune from 1197, the town itself was strongly fortified, the most remarkable feature in its wall being the great Porte de Laon.

**Castle.**—The first recorded castle, on the hill above the town, was founded by Hervé, archbishop of Reims, at the beginning of the 10th century. Long disputed between the archbishops and various feudal magnates, it passed at the end of the 11th century to Enguerrand de Boves, founder of the house of Coucy. Rebuilt early in the 13th century by Enguerrand III, the castle then had a *donjon* about 180 ft. high and 103 ft. in diameter. Sold to Louis de France, duc d'Orléans, in 1400, Coucy passed to the French crown on the accession of Louis XII. Granted in apanage to Claude de France (later Francis I's queen), to Diane de France (from 1576 to 1619), to François, comte d'Alès (d. 1622), and, in 1673, to Philippe, duc d'Orléans, it remained with the house of Orléans, except during the Revolution and the first empire, till 1856, when it became state property. During the Fronde, Cardinal Mazarin had its fortifications dismantled (1652). Restored in the 19th century, the castle was destroyed by German forces in 1917–18.

**Sires de Coucy.**—Enguerrand de Boves (d. 1115) distinguished himself as a crusader. His son Thomas de Marle was a brigand and rebel against whom Louis VI of France had to undertake two expeditions. Enguerrand III fought for Philip Augustus at Bouvines, but took part in the disturbances during Blanche of Castile's regency. In the 14th century, as Enguerrand IV left no heirs, Coucy passed to a nephew, Enguerrand de Guyenes. Enguerrand VI, who married Catherine, daughter of the Habsburg Leopold I of Austria, was killed at Crécy in 1346. His son Enguerrand VII, who married Isabella, daughter of Edward III of England, tried to stay neutral in the Anglo-French war, attacked the Austrian possessions in Switzerland (1375–76) on the pretext of securing his mother's inheritance and finally joined the Hungarian crusade against the Turks. Captured at Nicopolis (Nikopol), he died in Turkey in 1397. His daughter Marie sold Coucy to the duc d'Orléans in 1400.

See E. Lefèvre-Pontalis, *Le Château de Coucy*, 2nd ed. (1928).

(M. M.)

**COUÉ, ÉMILE** (1857–1926), French psychotherapist whose formula, "Every day, and in every way, I am becoming better and better," became proverbial, was born at Troyes on Feb. 26, 1857. From 1882 to 1910 he worked as an apothecary at Troyes, and in 1901 began to study hypnotism and suggestion under H. Bernheim and A. A. Liébault. In 1910 he established a free clinic at Nancy for the practice of his own psychotherapeutic method. Based on the power of imagination rather than of the will, his naïve and empiric system utilized formulas, repeated again and again in a confident voice, especially at a time when the mind was most receptive, to sink into the subconscious and to eliminate ideas tending to cause distress and disease. Coué always stressed that he was not primarily a healer but one who taught

others to heal themselves, although he also claimed to have effected organic changes by means of suggestion. His teaching for a time spread rapidly, and enormous audiences attended his lectures in England and the United States. Coué died at Nancy on July 2, 1926.

See Charles Baudouin, *Suggestion and Autosuggestion* (1921). (W.R.B.)

**COUES, ELLIOTT** (1842–1899), U.S. naturalist who did pioneer research in ornithology and mammalogy, was born in Portsmouth, N.H., Sept. 9, 1842. He was graduated in 1861 from Columbian college (now George Washington university), Washington, D.C., and from the medical school of that institution in 1863. In 1864 he was appointed assistant surgeon in the U.S. army. At the age of 30, he published his *Key to North American Birds*, which, with its revisions (1884 and 1901) and his revision of *New England Bird Life* (Stearns), did much to encourage systematic study of ornithology in America. This was one of the first works to introduce the "key" method of botanical manuals into zoology, and it is notable for its accuracy and completeness of citation and the convenience of its concise descriptions. In 1873–76 Coues was attached to the United States Northern Boundary commission, and in 1876–80 to the United States Geological and Geographical Survey of Territories, the publications of which he edited. His journeys enabled him to publish admirably annotated editions of the Lewis and Clark expedition (1804–06) and of Zebulon Pike's exploration of the upper Mississippi and Rocky mountain regions (1805–07).

Coues was a lecturer on anatomy in the medical school of Columbian in 1877–82, and professor of anatomy there in 1882–87. He was a founder of the American Ornithologists' union and edited its publication, *The Auk*, and several other ornithological periodicals.

In addition to ornithology Coues did valuable work in mammalogy, his book *Fur-Bearing Animals* (1877) being distinguished by the accuracy and completeness of its description of species. He worked on the *Century Dictionary* for several years, was associate editor of the magazine of ornithology, *The Osprey*, and edited journals of exploration. He died in Baltimore, Md., on Dec. 25, 1899.

**COUGH**, a reflex initiated when the respiratory tract is irritated by infection, noxious fumes, dusts or other types of foreign bodies. The reflex results in a sudden expulsion of air from the lungs that carries with it excessive secretions or foreign material from the respiratory tract. Cough is beneficial; pneumonia frequently results when an effective reflex is lost as a result of chest injury, disease or oversaturation. Repeated and severe coughing, however, is physically exhausting and interferes with rest. Under these circumstances drugs (especially opiates) may be used to suppress the reflex.

Cough occurs in many of the acute infectious diseases including the common cold, in the majority of chronic pulmonary diseases and frequently in heart disease. Any cough that persists longer than a few weeks should receive medical attention because it may be the first warning of serious disease. (H.A.D.)

**COULOMB, CHARLES AUGUSTIN DE** (1736–1806), French physicist, a pioneer in electrical theory, was born in Angoulême, on June 14, 1736. He was a military engineer, and after spending nine years in the West Indies he returned to France with his health much impaired. In 1789, on the outbreak of the Revolution, he retired to a small estate at Blois and devoted himself to scientific research. In 1802 he was appointed an inspector of public instruction; he died in Paris on Aug. 23, 1806. The Coulomb, an electrical unit, was named in his honour.

Coulomb designed the torsion balance independently of Michell in 1777. He published papers on friction as applied to machinery (1779); on windmills (1781), and on the torsional elasticity of metal and silk fibres (1784). His electrical papers were published in the *Mémoires de l'Académie royale des sciences* between 1785 and 1789; these formed the basis of the mathematical theory of electricity of Poisson.

The first three memoirs appeared in 1785, the following numbers in 1786, 1787, 1788 and 1789. In these memoirs Coulomb

gave an account of his work with the torsion balance in verifying Priestley's law of electrical repulsions. He extended the case to include attractions and finally stated that the force is proportional to the product of the charges and inversely proportional to the square of the distance between them (Coulomb's law). He also verified the inverse square law for particles of magnetic fluid; he believed in the two-fluid theory, but assumed that the magnetic fluids could not be separated but that the electric fluids were separable.

In the fourth memoir Coulomb showed that an electric charge is confined to the surface of a conductor and he compared the distribution of charge on the surface of conductors. He virtually established the result that the electric force near a conductor is proportional to the surface density of electrification (this was later proved by Poisson); he also stated that in the case of action at a distance the intervening medium played no part. Cavendish had anticipated Coulomb in the statement of the inverse square law, but this work was unpublished until many years after his death.

See **ELECTRICITY: Electrostatics: Coulomb's Law**; see also references under "Coulomb, Charles Augustin de" in the Index.

**COULTER, JOHN MERLE** (1851–1928), U.S. botanist and educator, whose work centred on plant morphology and taxonomy, was born at Ningpo, China, on Nov. 20, 1851, the son of missionary parents. He graduated from Hanover college, Hanover, Ind., in 1870 and pursued further study there and at Indiana university, receiving from the latter in 1882 the degree of doctor of philosophy.

After serving as botanist with the U.S. geological survey in the Rocky mountains in 1872–73, he was professor of natural sciences at Hanover college in 1874–79, professor of biology at Wabash college in 1879–91, president and professor of botany at Indiana university in 1891–93 and president of Lake Forest university in 1893–96. From 1896 to 1925 he was professor and head of the department of botany at The University of Chicago. In 1923 Coulter was made a member of the National Research council and in 1925 became adviser of the Boyce Thompson Institute of Plant Research at Yonkers, N.Y.

For more than half a century Coulter was an active botanical investigator and educator, producing early in his career valuable manuals for the study of Rocky mountain and Texan plants and later building up an important graduate department in botany in which many U.S. leaders of plant research were trained. In 1875 he founded the *Botanical Gazette*, of which for more than 50 years he was editor.

Coulter died at Yonkers, N.Y., Dec. 23, 1928.

Coulter's longer works include: *Manual of Rocky Mountain Botany* (1885); *Botany of Western Texas* (1891–94); *Plant Relations* (1899); *Plant Structures* (1899); *Morphology of Gymnosperms* (1901; 3rd ed., 1910) and *Morphology of Angiosperms* (1903), both with C. J. Chamberlain; *New Manual of Botany of the Central Rocky Mountains*, with A. Nelson (1909); *Fundamentals of Plant Breeding* (1914); *Evolution of Sex in Plants* (1914); *Plant Genetics* (1918); and *When Evolution and Religion Meet*, with Merle C. Coulter (1924).

**COUMARIN**, a fragrant chemical substance that occurs in sweet woodruff, the tonka (tonqua) bean, sweet clover (*Melilotus*) and many other plants. The fragrance of newly mown hay is largely due to its presence. Coumarin is widely applied in perfumery for the preparation of the sweet woodruff essence, as a flavouring agent and to scent tobacco. It can be obtained from the tonka bean, known to the natives of tropical South America as *cumaru*, by extraction with ethanol.

Coumarin,  $C_9H_6O_2$ , is the lactone derived from *cis-o*-hydroxycinnamic acid (coumarinic acid), which is not known in the free state because it cyclizes to coumarin as soon as it is liberated from solutions of its salts.

Coumarin was the first natural perfume to be synthesized from a coal-tar chemical and was made by the action of acetic anhydride and sodium acetate on salicylaldehyde (Sir William Perkin, 1868). It forms rhombic crystals melting at 67° C., which are readily soluble in ethanol and moderately soluble in hot water.

The coumarin nucleus is comparatively resistant to oxidation and the benzene part of the ring system is not as reactive as that of a simple benzene derivative. The chemical behaviour of coumarin is explained only partly by the lactonic structure since the  $\alpha$ -pyrone ring is rather difficult to open with alkali while acids likewise do not readily affect it.

On boiling with concentrated potassium hydroxide, coumarin yields the potassium salt of *o*-coumaric acid. The double bond between carbon atoms 3 and 4 in the coumarin nucleus (see structural formula, below) is highly reactive; it adds bromine, hydrogen cyanide and sodium bisulfite with great facility. Catalytic hydrogenation under pressure converts coumarin to dihydrocoumarin which upon opening of the lactone ring forms melilotic acid,  $C_9H_{10}O_3$ .

There are many coumarin derivatives widely distributed in the plant world. Most of them are hydroxycoumarins—the 6,7-dihydroxy derivatives being dominant. Some occur as glycosides. Alkylated hydroxycoumarins also occur.

Coumarin itself has very little physiological action on mammals, but many of the synthetic 3-substituted-4-hydroxycoumarins have potent anticoagulant properties. The causative agent of the hemorrhagic sweet clover disease of cattle is 3,3'-methylenebis-(4-hydroxycoumarin). The synthetic product called Dicumarol (U.S. registered trade-mark) is widely used in clinical practice as an orally administered anticoagulant to combat various thromboembolic syndromes (coronary thrombosis, pulmonary embolism, etc.).

Another synthetic 3-substituted-4-hydroxycoumarin, the highly potent warfarin, has revolutionized rat and mouse control. Its anticoagulant action is not detectable by the rodent. When baits containing 0.025% warfarin are eaten for from three to five days, fatal internal hemorrhage results in from seven to ten days. The 3-sodium derivative of warfarin is also used clinically like Dicumarol®.

Structural formulas of coumarin and related substances are:

(K.P.L.)

**COUNCIL**, in the Christian Church, is a meeting of bishops and other leaders to consider and rule on questions of doctrine, administration, discipline, etc. An ecumenical or general council is a meeting of bishops of the whole church; local councils representing provinces, patriarchates and so on are often called synods. According to Roman Catholic doctrine a council is not ecumenical unless it has been called by, and its decrees are not binding until they have been promulgated by, the pope. Decrees so promulgated possess the highest authority.

Outside the Roman Catholic Church, most Christians assert that there have been no ecumenical councils since the schism that di-

vided Eastern and Western churches; hence only the first seven councils are recognized. Roman Catholics accept 14 later councils (including the Vatican council that began in autumn 1962) as ecumenical.

Synods, councils and conferences on a small scale have played a part in the Protestant churches and in times of crisis have achieved more than local or temporary significance. Examples of such are the Westminster assembly (1643), whose purpose was the reformation of the English church; the Synod of Dort (1618-19), an assembly of the Dutch Reformed Church to deal with Arminianism; and the Synod of Barmen (1934), at which the major German Protestant confessions declared their opposition to Nazism. In the 19th century there was a growth of national and world consultative organizations in the various Protestant denominations, and this has continued. The formation of the World Council of Churches (*q.v.*) in 1948 may herald the beginning of a Protestant conciliar movement of ecumenical scope. (X.)

**Origins.**—The name council was applied in the most primitive times to any church meeting and even to buildings where services were held. As the theory of government by bishops was expounded during the 3rd century, the word council came to have the special sense of meetings of bishops, though not only bishops were present, for the administration of the church. There had long been meetings of the entire congregation, the bishop with his presbyters and deacons and the faithful, and this was the foundation of the later diocesan synod. But as the church grew, its problems could be solved only by meetings of the heads and representatives of the various churches. Each bishop was regarded as the special voice of his church and its tradition, as the apostolic teacher representing an apostolic tradition. He came to a provincial council to utter his judgment upon such pastoral problems as the treatment of apostates or adulterers, or, if there were question of heresy, to declare the faith received in his church and presumed always to have been taught there since its foundation.

The earliest-known provincial councils were held in the 2nd century to pronounce judgment upon an eastern sect of Phrygia, the Montanists, and to settle a disagreement between churches over the mode of celebrating Easter. In Cappadocia during the 3rd century there seem to have been annual meetings. Persecution was a fruitful source of pastoral problems, and many of the earliest councils were concerned with it. By 300 the meetings of bishops in the province had become the habitual mode of church government. These gatherings looked back to the apostolic meeting at Jerusalem in Acts xv as their prototype, and believed that such meetings were specially under the inspiration of the Holy Spirit. Their decisions, known as canons, were already beginning to form a series of precedents, though the work of collecting and codifying had not yet begun (see CANON LAW).

The growth of conciliar action was especially affected by the development of the authority of the greater sees. The bishop of a provincial capital soon gained a special place in councils, but even in the capital cities, like Rome and (after the transfer of the capital) Constantinople, there was often a local synod of resident or visiting bishops gathered round the pope or patriarch.

In nearly every provincial synod in this primitive period presbyters, deacons and sometimes laymen shared with the bishops in the council. But it is clear from the writings of Cyprian that bishops were always the decisive voice, and only the bishops signed the letters issued by the synods in the province of Africa. Elsewhere presbyters often signed as representatives of their bishops, but other presbyters and laymen are also found signing. After the conversion of Constantine I the emperors summoned and sometimes presided at councils. In the kingdoms of the west lay lords sat with the bishops; and in England, Spain and France the distinction between the ecclesiastical council of the nation and the national council was not always easy to perceive. Nevertheless the distinction was never submerged. It was understood that there was a difference between the local law of the land and the universal law of the church, and that in the declaration of the latter the laity were subject to the decisions of the bishops.

**General Councils.**—With the end of persecution under Constantine I, it seemed possible and natural that bishops from more

than one province should be convened to a general council. Even before the conversion of Constantine, a decision accepted by a series of provincial councils became in normal practice a binding one. Thus Tertullian wrote of the "councils of the churches" which declared the *Shepherd of Hermas* (see *APOSTOLIC FATHERS*) not to be an authentic part of the New Testament. To a council from a wider area was inevitably attributed a more general authority, and as early as 314 Constantine had summoned such a "general" council to Arles to deal with the problems of the Donatist schism.

A distinction must be made at first between councils loosely called general and those which later achieved the status of general or ecumenical councils. No one knew in the beginning that there was such a status to achieve; and any great council, with bishops representing several provinces, would regard itself as especially important and its authority as proportionately higher than that of a provincial council. When the idea of an ecumenical council had come into existence and had been fully established during the 5th century, there were several attempts by councils to be ecumenical and several councils which believed themselves to be ecumenical, though their claim was disallowed, and occasionally abhorred, by the later tradition of the church.

The idea of an ecumenical council was slow to take shape or, rather, its authority was defined but slowly. The term ecumenical synod was first used by the historian Eusebius (in his life of Constantine) to describe the council summoned by Constantine to meet at Nicaea in 325. Between such imperially summoned synods and ordinary provincial synods there was a patent difference, but a difference more of practice and repute than of defined authority. The decisions of such a council were obviously more binding than were those of earlier councils, since the emperor made them effective in secular law. The Council of Nicaea met not in a church but in part of the royal palace and the emperor was present for some of the time, taking an effective part in the discussion. The government made provision to pay the expenses of bishops who attended the Council of Nicaea and later councils of the 4th century. Ammianus Marcellinus grumbled that the imperial postal service was seriously hindered by the bishops going to and from councils, and Pope Liberius tried to persuade the emperor Constantius to summon a council with the plea that the bishops would travel at their own charges. It was soon observed that the privilege might diminish the independence of the bishops in a matter where the emperor was known to hold strong opinions; at the Council of Ariminum (Rimini) in 359 most of the bishops refused their expenses on this ground, and it was noted as a sign of the poverty of three bishops from Britain that they were compelled to accept help from the public funds.

But though the relation to the emperor and the possibility of summoning bishops from all parts of the empire patently made much practical difference to the nature of the council, it was not at first evident that there might be a peculiar sacredness about the decisions of such a council. All councils were believed to meet under the guidance of the Holy Spirit. In matters of faith, since theoretically the bishops came to the councils not to make new decisions but to declare the ancient faith of the church, it was not clear how a council assembled from the whole empire was more "irreformable" than a series of councils in parts of it. In matters of discipline later councils habitually corrected or revised the decisions of earlier councils. The eastern bishops who disliked the Creed of Nicaea continued for many years to work for its revision. The long fight, led by Athanasius, to defend the Creed of Nicaea and its word *homoousios* began about 359-360 to attribute a peculiar and exceptional sanctity to the decision of Nicaea, a sanctity which carried with it the implication that the Creed of Nicaea was not reformable by a later council. Athanasius was not slow in arguing that this specially sacred nature of the council arose from its universal representation. By the 5th century the historian Socrates declared that the Nicene fathers could not depart from the truth because they were enlightened by the grace of the Holy Spirit. The Councils of Ephesus (431) and Chalcedon (451) declared that the decisions of Nicaea were unalterable.

It was assumed, rather than formally stated, that ecumenical councils, once recognized to be such, could not err. In the 6th century the emperor Justinian I ordered all bishops to subscribe to the first four councils, on the ground that we receive them as we receive the Holy Scriptures; and a little later Pope Gregory the Great mentioned the four councils in the same breath as the four Gospels. In practice this idea of irreformable canons was often confined to matters of faith. In matters of discipline later councils continued to alter the decisions even of the councils recognized as ecumenical, for changing circumstances had made the old canons irrelevant or unenforceable. Nevertheless there was never a clear distinction of doctrine between the canons of faith and the canons of discipline.

#### *Ecumenical Councils*

##### *Recognized by Both Eastern Orthodox and Roman Catholics*

1. First Council of Nicaea (325)
2. First Council of Constantinople (381)
3. Council of Ephesus (431)
4. Council of Chalcedon (451)
5. Second Council of Constantinople (553)
6. Third Council of Constantinople (680-681)
7. Second Council of Nicaea (787)

##### *Recognized by Roman Catholics*

8. Fourth Council of Constantinople (869-870)
9. First Lateran Council (1123)
10. Second Lateran Council (1139)
11. Third Lateran Council (1179)
12. Fourth Lateran Council (1215)
13. First Council of Lyons (1245)
14. Second Council of Lyons (1274)
15. Council of Vienne (1311-12)
16. Council of Constance (1414-18)
17. Council of Ferrara-Florence (1438-c. 1445)
18. Fifth Lateran Council (1512-17)
19. Council of Trent (1545-63)
20. First Vatican Council (1869-70)
21. Second Vatican Council (1962- )

The Roman Catholic Church recognizes eight and the Orthodox Eastern Church seven ecumenical councils before the schism between east and west in 1054 (see table). For the east this in practice closed the series; for the west, the nature of a general council changed. Hitherto it had in every case been held under imperial protection, summoned by the Byzantine emperor, and in only one case (Ephesus in 431) held more than a few miles from Constantinople. After the schism the increasing centralization of the Latin Church under the see of Rome made that see the single effective convener of general councils, which only special circumstances kept away from the Lateran or Vatican.

#### COUNCILS TO THE 9TH CENTURY

**First Council of Nicaea (325).**—After Constantine I had made himself sole emperor in 324, he addressed himself to healing the principal conflict raging in the Eastern Church, that over Arianism; in this effort he used the same method he had used in the west over Donatism when he summoned the Council of Arles of 314. It was originally decided that this ecumenical council should meet at Ancyra (Ankara), but, perhaps for the convenience of the western delegates as well as of the emperor, the meeting was transferred to the royal palace at Nicaea. To Nicaea came about 220 bishops, out of whom only five are known to have come from western countries, though the list is incomplete. The five included Ossius, the bishop of Córdoba, but not the pope, who sent two representatives. (The pope was not personally present at any of the first eight ecumenical councils; and though he was in Constantinople while the fifth council was being held in 553 he pleaded as a reason for not participating that it was not the custom of his predecessors. He was represented by legates, except at Constantinople in 381 where he was neither summoned nor represented.)

No reliable account of the proceedings has survived; only the agreed creed, the 20 canons and the synodical decree are extant. It is difficult to suppose that no report of the proceedings was taken, but none was extant even in the later 4th century. The emperor, though unbaptized and a catechumen, presided in state at the opening and took an active part in the discussions. It seems

to have been his personal influence which decisively swayed the divided council to accept, almost unanimously, the proposed creed supported by his chief advisers and containing the word *homoousios*, "of one substance"; i.e., with the Father, applied to the Son. (For a discussion of the theological issues, see **ARIANISM**; **CREED: Nicene Creed**.)

No one knows whether Constantine himself understood what was at stake. The word *homoousios* appeared to rule out the subordination of the Son to the Father for which Arius had contended. But many eastern bishops were reluctant to accept the word. They shrank from including in the creed a word not drawn from scripture; they feared that its suggestion of absolute equality or even identity between Father and Son would encourage the error of the Sabellians, who regarded Jesus' life as a simple manifestation of the Creator God. The language of some eastern bishops indicates that their acceptance of the term was not due to theological conviction. The council also condemned Arius; and the eastern bishops, with two open exceptions, did not question that he had rightly been condemned. The emperor exiled Arius from Egypt until he accepted the Creed of Nicaea. It thus appeared convenient that the decisions of a council should be implemented by the secular power; but as an inconvenient consequence, it soon became apparent, bishops of a small minority need not despair if they could secure the support of an emperor.

The synodical decree of the Council of Nicaea attempted, though unsuccessfully, to establish a uniform date of celebrating Easter, in accordance with the custom of the great majority of the churches. The canons confirmed the authority of the bishop of Alexandria over other bishops in Egypt and Libya, and of other metropolitans (canon vi), thereby taking a long stride toward the creation of effective patriarchates; and allowed the bishop of Jerusalem a primacy of honour in his province, though it left him without jurisdiction (vii). They decreed a time of catechumenate for converts before their baptism or ordination (ii); forbade the clergy to have unmarried women in their houses (iii), apparently even as housekeepers; decreed that a bishop should be consecrated by three bishops at least and with the approval of his metropolitan (iv); condemned the lending of money at interest by clerics (xvii); ordered that Christians should pray standing on Sundays and from Easter to Pentecost (xx); and forbade bishops, priests or deacons to move from one church to another (xv).

The 5th-century historian Socrates says that the council intended to make a canon enforcing celibacy of the clergy upon all bishops, priests and deacons. The unmarried bishop Paphnutius from Egypt said that "too heavy a yoke ought not to be laid upon the clergy," and prevented the canon, though he would have permitted a canon forbidding those who were ordained when unmarried to marry after ordination.

**Councils Between 325 and 381.**—After the death of Constantine (337) the eastern bishops put out various creeds and doctrinal statements which condemned Arius but did not contain the *homoousios* and were directed against the Sabellians. The prolonged controversies of the 4th century were part doctrinal, part personal. The only weapon of the church for solving these problems was the council, and indefatigable endeavours at numerous councils were needed to reach any solution that would be generally acceptable in east and west. The personal acrimony and rival orthodoxies left even some contemporary observers with a distaste for councils—"Venerable bishops," said Gregory of Nazianzus ironically, "who put their personal squabbles before questions of faith." "For my part," said the same writer sadly, "to speak the truth, I prefer to avoid all councils of bishops. I have never seen a council which ended well or cured evils—on the contrary." For the last 16 years of his episcopate, Martin of Tours, whose experience of bishops had been as unhappy as Gregory's, refused to attend the provincial councils of Gaul. But these consequences were probably inevitable during the political divisions of the empire during the 4th century. No other ultimate authority was in those days conceivable, whatever eminence in jurisdiction might be accorded to the patriarchs.

Probably the most important council, in long perspective, of this period of councils between 325 and 381 was the Council of

Sardica (Sofia) in 342 (or, as some believe, 343). This had been intended as an ecumenical council, but the easterners refused to attend when they found that the western bishops insisted on the presence of Athanasius and others who had already been deposed by lawful synods. The decisions of the western council at Sardica did nothing to solve the conflict. But the canons passed there were taken into western canonical collections, tacked on to the Nicene canons without break or scribal mark, in such a way that sometimes they were quoted as "Nicene" and thereby gained spurious ecumenical authority. The canons of Sardica ruled that a bishop must first have been ordained reader, deacon and priest and not consecrated as a simple layman (xiii); bishops ought not to be consecrated for every little town, for fear of lowering the dignity of the episcopate (vi); translations of bishops from see to see are forbidden (i); bishops must reside in their dioceses and (characteristic of the 4th century) must not travel to other dioceses without good reason, and even with good reason must remain there as short a time as possible (xiv, xv). They ruled also that if a bishop is deposed by the bishops of his province he has a right of appeal to the see of Rome: if the pope holds that there is no case for revision, the appeal is disallowed; if he holds that there is a case, he must refer it to the bishops of a neighbouring province as a court of final appeal (vii). This last piece of legislation remained a dead letter. The Nicene faith was not finally established till the Council of Constantinople in 381. In the later stages of the debate the Cappadocian fathers, led by Basil of Caesarea, not only brought the old eastern conservatism to lose its fear of the *homoousios*, but examined the theology of the Holy Spirit in such a way that when the settlement was reached in 381 it was a full definition of trinitarian doctrine.

**First Council of Constantinople (381).**—Theodosius I, who was a strong defender of the Nicene faith, became emperor of the east in 379 and summoned a council of eastern bishops, some 150 attending. Again the minutes of the council are not extant. The council declared for a creed that was substantially the creed of Nicaea with the alterations that make it the Nicene (Niceno-Constantinopolitan) Creed as subsequently known to the church. It finally declared the doctrine of the equality of the Holy Spirit with the Father and the Son, and therefore may be regarded as the end of a long debate upon the trinitarian doctrine. In both these doctrinal decisions it recovered unity between east and west. The third canon of the council gave the bishop of Constantinople precedence of honour over all other bishops except the bishop of Rome, "because Constantinople is the New Rome." The second canon limited the influence of the eastern patriarchs to their own provinces, thus particularly limiting the power exercised by the see of Alexandria under Athanasius and his successors. Peter of Alexandria had lately and high-handedly consecrated a bishop of Constantinople, and it is probable that the canon was directed mainly against this sort of act. The council requested the emperor to seal the decisions, and Theodosius gave them legal effect.

Though only eastern bishops had been summoned, the Greeks claimed this council to be ecumenical. Pope Damasus (366-384) appears to have accepted the creed but not the canons, at least not the canon upon the precedence of Constantinople. But exactly when the council achieved the ecumenical status comparable with that already achieved by Nicaea is not easy to determine. The third ecumenical council at Ephesus in 431 still held the Council of Nicaea in a unique place of honour. Not until the Council of Chalcedon (451) does the ecumenical status of this council of 381 appear to be undoubted. Rome continued thereafter to protest against the award of precedence to Constantinople. About 485, Pope Felix III wrote of three ecumenical councils, Nicaea in 325, Ephesus in 431, Chalcedon in 451. Pope Gregory the Great and his successors decisively acknowledged the ecumenical character of the creed. The see of Constantinople was first allowed precedence by Rome after it had become Latinized as a result of the fourth crusade (1204). Thus, in inquiring into the nature of the authority of ecumenical councils in the Latin church, it should be observed that the dogmatic authority of this council was not recognized as binding until the 6th century, and its regulation of sees not until the 13th.

**Council of Ephesus (431).**—After the settlement of the Arian question, and its corollary in the doctrine of the Holy Spirit, theological debate moved into the realm of the doctrine of Christ's Person, the relation of Godhead and manhood in one who was both God and man. One trend of thought, exemplified by Apollinarius and by Monophysitism and expounded in Alexandria, concentrated upon the Word as the subject inhabiting the God-man, emphasizing Jesus as God but appearing to minimize the full and true nature of his manhood. Another trend, exemplified by Theodore of Mopsuestia and Nestorius and in Antioch, emphasized his complete manhood and used uncertain language about the way in which the Word dwelt in that manhood.

Nestorius, who became patriarch of Constantinople in 428, declared that the word *Theotokos* ("God-bearer"), as applied to the Virgin Mary, long used at Alexandria and hallowed in popular devotion, was unsuitable or doubtful. Cyril of Alexandria held that Nestorius had fallen into the opposite error of suggesting two Sons of God who dwelt together in Jesus. (For a detailed discussion of the theological controversy, see CYRIL, SAINT; JESUS CHRIST: *The Dogma of Christ in the Ancient Councils*; and NESTORIUS.) The conflict between the ancient rights of the see of Alexandria and the new claims of the see of Constantinople played a large part in the struggle. Theodosius II summoned a general council to meet at Ephesus on June 7, 431.

The proceedings at Ephesus were extraordinary. The bishops from Antioch and its province failed to arrive till June 26; and meanwhile, on June 22, Cyril of Alexandria held a council of some 200 bishops under his own presidency and deposed Nestorius, who refused to attend or recognize it. On June 26 the Antiochenes arrived under their patriarch, John, and held a council of 43 bishops in which they deposed Cyril. On July 10 the pope's legates arrived from Rome and declared for Cyril's council; this is the council recognized as ecumenical.

The principal decision of the council was the condemnation of Nestorius, a decision primarily disciplinary, not doctrinal, especially as doctrinal debate continued as ardently after the council as before it. The council looked with favour upon 12 anathemas pronounced by Cyril against Nestorius and read at the council, evidently approved by the delegates, included in the acts over their subscriptions, but not formally declared to be binding. It has commonly been assumed in Christendom that the council thus condemned the disapproval of *Theotokos* and other particularly Nestorian language which minimized the unity of Godhead and manhood or treated the incarnation as an association between God and the man Jesus rather than as the assumption of manhood by the divine Word.

The council declared that no one might make innovations on the Creed of Nicaea (proper, not the creed of 381 now called Nicene) and condemned the opinions of the Pelagian Celestius, though without specifying which opinions it was condemning (perhaps his alleged denial of original sin and the doctrine that the grace of God is given to a man in accordance with his merits). The Roman legate Philip asserted at the council that St. Peter still lives and judges in his successors, and these famous words were received by the council without protest.

In default, however, of any indubitable statement of what opinions in Nestorius and Celestius the council was condemning, it is not easy to consider the decrees of the Council of Ephesus as being of decisive dogmatic authority. Nestorius in fact was sent into exile by the emperor. The continuing conflict between the Antiochene bishops on the one side and Cyril and Rome on the other was resolved by the "formulary of union" in 433, which accepted *Theotokos* with an explanation, used the phrase "union of two natures" and in one phrase allowed that the two natures persisted after the union. It was left uncertain whether Cyril's 12 anathemas, which to some had suggested a fusing of natures and had been abhorrent to the Antiochene bishops, had or had not been withdrawn.

**From Ephesus (431) to Chalcedon (451).**—Since the Council of Ephesus had defined nothing, the debate over the Person of Christ—his relation to the Father and the relation of divine and human within him—continued for the next 20 years. Cyril's ex-

treme supporters regretted that he had accepted a formula with the phrase "two natures," the extreme supporters of Antioch continued to regard Cyril as heretical. When Cyril died in 444 the more rigid wing of his party took control under his successor, Dioscorus, who was determined to reassert the "one-nature" language. In 448 the controversy centred upon the archimandrite Eutyches (*q.v.*), who taught that there were two natures before the incarnation, one nature after. He was excommunicated. Flavian, patriarch of Constantinople, informed the pope, Leo the Great, of Eutyches' heresy; and this was the occasion of the celebrated *Tome* of Leo (June 13, 449), which showed the vigorous opposition of the Roman see to the one-nature language. Eutyches appealed to Dioscorus, who persuaded the emperor to summon a general council at Ephesus (Aug. 449). This synod (known by Pope Leo's contemptuous nickname as *Latrocinium*, the "robber synod") vindicated Eutyches, deposed Flavian and all the chief defenders of two-nature language, dismissed the formula of union and anathematized the proposition that there were two natures after the incarnation.

**Council of Chalcedon (451).**—In 450 the emperor Theodosius II died and was succeeded by his sister Pulcheria and her husband Marcian, who were favourable to the two-natures group. Marcian summoned a general council (originally to Nicaea but transferred to Chalcedon before it began its sessions on Oct. 8, 451), the largest of the early councils, with about 520 bishops or their representatives present, and the best documented.

Unlike the bishops at Ephesus in 431, the bishops at Chalcedon defined doctrine. Their mode was to approve documents: the Creed of Nicaea (proper), the Creed of Constantinople (381, the so-called Nicene Creed), Cyril's two letters against Nestorius (which excluded Nestorianism as Cyril believed it to be and therefore insisted upon the unity of persons in Christ, and approved the *Theotokos*), Leo's *Tome* (which excluded the one-nature language and insisted upon two natures after incarnation). They also composed a confession of faith:

Jesus Christ is one and the same Son, the same perfect in Godhead and the same perfect in manhood . . . begotten from the Father before the ages as regards his Godhead, . . . and from the Virgin Mary, the *Theotokos*, as regards his manhood; . . . made known in two natures without confusion, without change, without division, without separation, the distinction of natures being by no means taken away by the union.

The council also deprived Dioscorus and others of his party.

The council made certain regulations for pastoral discipline, especially subjecting monks to their bishops, prohibiting the clergy from farming or business and ordering that no one should be ordained without a pastoral charge. It elevated the see of Jerusalem to the status of a patriarchate in Palestine, hitherto under the see of Antioch, and elevated the see of Constantinople to the status of a patriarchate over Pontus, Asia and Thrace. This last resolution (the 28th canon) encountered the protests of the papal legates, and the see of Rome never accepted it. Its existence delayed Pope Leo's acceptance of the dogmatic definitions until 453.

The Council of Chalcedon, by its first canon, confirmed a code of canons which its members were using, and thereby gave a measure of ecumenical authority to canons of earlier local or provincial councils. The collection of canons included not only the ecumenical councils of Nicaea (325) and Constantinople (381) but also local synods of Ancyra (314), Neocaesarea (early 4th century), Gangra (middle of the 4th century) and Antioch (ascribed to 341, but probably held about 328-330). This book of canons seems to have been received implicitly in the east before the Council of Chalcedon stamped it with a more authoritative approval. But the nature of this approval is doubtful, nor perhaps would Latins have perceived clearly what was being approved. Many of the earlier canons are concerned with pastoral problems of the lapsed and are appropriate only to conditions of persecution. The tenth canon of Ancyra permits deacons to marry after ordination if they have given notice at ordination of their intention. The 15th canon of Neocaesarea orders that the deacons be seven in number "even if the city be very great," and the first canon decrees that the priest who marries after ordination shall be deposed. For the most part this collection of canons bears

witness to a primitive state of church life that had passed away when the Council of Chalcedon met.

**After Chalcedon.**—By the time the fathers met at Chalcedon in 451 the western part of the Roman empire had already begun to break into the pieces which later became the barbarian kingdoms. There was a period of codification, both in Italy and the east (see CANON LAW), and the four general councils were canonized as the rule of orthodoxy, so that Gregory the Great at the end of the 6th century could say that he revered them as he revered the four Gospels. In the east the decrees of Chalcedon encountered resistance from the churches which were disciples of the one-nature doctrine, and in Egypt, Syria or Armenia there was Monophysite schism (see MONOPHYSITES). The emperors in Constantinople vacillated about the best means of holding together their religiously divided empire. A proposal by the emperor Zeno (the *Henoticon*, 482) that Chalcedon be quietly dropped and agreement founded upon the first three councils failed disastrously, and its failure showed that no agreement could be reached except by receiving the decree of Chalcedon while seeking to modify it. Justinian I, emperor from 527 to 565, himself theologically qualified and the more concerned for the religious division because his troops were recovering control of Rome and Italy, tried various expedients for modifying Chalcedon.

One scheme (543) was to condemn the "Three Chapters," the Antiochene two-nature subjects that had been approved by Chalcedon: the person and writings of Theodore of Mopsuestia; the writings of Theodoret of Cyrrhus against Cyril's 12 anathemas; and a letter of Ibas, bishop of Edessa, which also attacked the 12 anathemas. These three were much complained of by those inclined to Monophysitism. The plan of condemnation ran into vigorous opposition from all those for whom Chalcedon had become sacred. To condemn the Three Chapters seemed to be calling in question the immutable nature of the decrees and therefore the ecumenical status of the council. Justinian summoned a general council in 553 and used stringent measures to persuade all the parties to conform.

**Second Council of Constantinople (553).**—The council opened on May 5, 553, with 165 bishops under the presidency of Eutychius, patriarch of Constantinople. Pope Vigilius of Rome, who had been summoned to Constantinople, opposed the council and took sanctuary in a church. The council condemned the Three Chapters. The pope continued his resistance until Dec. 8, 553, when he informally accepted the verdict of the council; he ratified it formally on Feb. 23, 554.

The 14 anathemas put out by the council further strengthened the case against any Nestorian interpretation of Chalcedon by insisting yet further upon the unity of the Person of Christ in the two natures. The only other important act of the council was to ratify an earlier condemnation of Origen, though what opinions were condemned is not evident from the acts of the council. From the relevant documents used by the bishops, it appears that the doctrine of the soul's existence before birth was the chief offense. The western church, devoted as it was to Chalcedon, could not bring itself to accept the decrees of the council of 553, even though the pope had accepted them. In Africa imperial troops were able to force acceptance. North Italian bishops refused their allegiance to the see of Rome and found support in France and Spain. The opposition hung on in northern Italy until the end of the 7th century. By then the coming of Islam into those provinces of the east which had been inclined toward Monophysitism rendered obsolete all such plans for compromise.

**Third Council of Constantinople (680) and Trullan Council (692).**—The arguments over Chalcedon, however, were not ended. Some easterners, forbidden to talk of one nature, thought to enforce the unity of the Person of Christ by talking of one will (Gr. *thelema*) and one operation (*energeia*) from the two natures, and thereby are called Monothelites (*q.v.*). Sergius, patriarch of Constantinople from 610 to 638, seems to have been the principal author of this language. The doctrine of one will was enshrined in the *Ecthesis* of 638, published under the name of the emperor Heraclius but probably drafted by Sergius. The pope of Rome, Honorius I, appears to have declared for the doctrine,

though his language leaves room for doubt. In reply to Constantine II's edict of 648, which imposed silence on all parties, a Lateran synod held under Pope Martin I in 649 supplemented the definition of Chalcedon by a statement affirming two wills and two operations. Martin was exiled to the Crimea, and the struggle between Rome and Constantinople continued. But with the emperor Constantine IV conciliation prevailed. In 680 he summoned a council at Constantinople which in its first session assumed that it was ecumenical. It condemned the Monothelites, among them Honorius, and asserted two wills and two operations. "Each nature with the communion of the other willed and wrought that which was proper to itself."

Another council met in 692 in the same imperial banqueting hall, called Trullus, at Constantinople, and this is known as the Council in Trullo, or, because it intended to be a supplement to the fifth and sixth general councils, the Quinisext council. Though Rome and the west were probably not represented, the fathers claimed to be a general council; but some of their canons were most unacceptable to the west and were in part directed against Roman customs (*e.g.*, celibacy of the clergy, rules for fasting). In the east the 102 canons of this council were added to those of the sixth ecumenical council and thereby acquired ecumenical authority (they were quoted as such by the seventh ecumenical Council of Nicaea in 787). Under this impression the west also received some of them.

**Second Council of Nicaea (787).**—In 726 the emperor Leo III the Isaurian issued his decree against the worship of icons and thereby precipitated the iconoclastic controversy. During all the middle years of the 8th century the controversy raged in the east (icons were condemned at a council, claiming to be general, at Hieria, near Chalcedon, in 754), slowly driving the popes, who decisively opposed iconoclasm, out of the arms of the Byzantine emperors to look for protection from the new western power in Carolingian France. In 780 the empress Irene began to retract the iconoclastic policy; and her iconodulic patriarch, Tarasius, requested the summoning of a council to re-establish the peace of the church (787). It was intended to be an ecumenical council, and on this ground Pope Adrian I sent legates. Tarasius presided, but the Roman legates signed first. The dogmatic decrees anathematized all heretics, including Pope Honorius and the leading iconoclasts, but did not condemn the Three Chapters. It declared that icons deserved reverence (Gr. *proskynesis*) but not adoration (*latreia*), which was due to God alone.

There were 21 disciplinary canons, one of which forbade further foundations of double (*i.e.*, for both men and women) monasteries.

The decrees of this council, though confirmed by the pope, were at first not well received in the empire of Charlemagne. This was partly the fault of the incompetent Latin translator of the acts, who, for example, translated *proskynesis* and *latreia* as though they were identical, thereby making it appear that the council was ordering Christians to worship icons as they worshiped the Holy Trinity. At the Council of Frankfurt (794) the dogmatic decree of Nicaea was repudiated, and the English church agreed with the repudiation. Even the great Pope Nicholas I, in the middle of the 9th century, still referred to the six general councils. As late as the 11th century the church in France recognized only six ecumenical councils, and some writers still gave the first four a place of special honour. But Rome's original verdict stood, and the second Council of Nicaea was accepted by the canonists as the seventh ecumenical council.

**Fourth Council of Constantinople (869-870).**—The fate of the canons of the Council in Trullo had proved that east and west were already slipping asunder, and the iconoclastic controversy had further driven a wedge between Rome and Constantinople. The rise of the Carolingian empire turned Rome's eyes westward, and there was never again to be the harmony between east and west that had earlier prevailed for such long periods. Later the eastern church for the most part recognized only the seven ecumenical councils. The Roman Catholic Church, after a period of uncertainty during which two popes allowed only seven ecumenical councils, by the end of the 11th century recognized as ecumenical the Council of Constantinople (869-870) that con-

firmed a Roman sentence of excommunication against the patriarch Photius (*q.v.*), though that act was reversed, with the approval of the Roman legates, at a further Council of Constantinople in 879-880. The 22nd canon of the council of 869-870 prohibited lay interference in episcopal elections; and for the canonists of the investiture struggle at the end of the 11th century this canon assumed great importance. (W. O. C.)

### COUNCILS OF THE WESTERN CHURCH

A period of over 250 years separated the eighth ecumenical council from the ninth. It was a period during which the papacy reached its lowest level of degradation, in which lay control and feudalism took possession of the western church, and in which, at least until the mid-11th century, theological activity was almost nonexistent. When, from 1059 onward, the reformed papacy became itself a principal agent of reform, and under Gregory VII and his successors pursued a policy of direct control and centralization, and when, concurrently with this, intellectual life revived and the study of theology was once more pursued at a high intellectual level, the pattern of the church had changed essentially in many respects.

In the first place, Christendom was now divided into Eastern and Western churches, though the ecclesiastical link was not broken till 1054 and even then not without hope of repair; and while the eastern emperor regarded himself as the heir and representative of the ancient empire, the emperor of the west was committed to a struggle for supremacy with the papacy. The papacy, for its part, had never retreated from its traditional claims and had been strengthened in their exposition by elements of law derived in part from the pseudo-Isidorian collection (*see DECRETALES, FALSE*); in consequence the pope now explicitly claimed that his was the sole and complete right of summoning a general council. At the same time the Eastern Church had fallen entirely out of the purview of Rome; both popes and western emperors had come to regard the Byzantines with suspicion and distrust, while the leaders of the Eastern Church regarded Rome as both barbarian and overbearing. Between the two parts of Christendom—of which the eastern was the more civilized and economically developed and the western the larger and now at last the more progressive—there existed no sympathy or sense of common cause.

Synods and councils were the principal means used by the popes of the reform in promulgating and enforcing their measures, and several such meetings were held in Rome. At the same time categories of those summoned had been widened to include abbots, representatives of cathedral chapters, and lay potentates, and the meetings had been called upon to settle or to register political and ecclesiastical measures rather than purely dogmatic questions. Thus Pope Calixtus II in 1122 had concluded an agreement with the German emperor, Henry V, at Worms on the question of investitures which terminated a long and vexatious conflict, and wished to clinch his achievement by a ratification by the clergy of the west.

**First Lateran Council (1123).**—No acts or any contemporary account of this council survive, and there is no reason to suppose that the pope consciously aimed at reopening the series of ecumenical councils. He did, however, invite bishops from all over the west, and the most credible estimate of those actually present is 300, to whom must be added abbots and others. The council probably lasted for ten days (March 18-28, 1123), and a number of canons (probably 22) were promulgated, many of which did no more than reiterate the decrees of earlier councils or the (forged) decretals. A large place was occupied by disciplinary or quasi-political decisions, of which some were corollaries of the recent settlement at Worms; thus simony was denounced, clerics in major orders were forbidden to have wives, laymen were prohibited from disposing of church property, unlawful episcopal consecration was forbidden and marriage between cousins was prohibited in general terms. There was no specifically dogmatic canon.

**Second Lateran Council (1139).**—This council was convoked by Innocent II in April 1139 primarily to condemn the followers of Arnold of Brescia (*q.v.*) and to end the schism caused by the

antipope Anacletus II, who had been elected almost immediately after Innocent. Opinion was divided at the time, and is still among scholars, as to where the precise canonical right lay in transactions of doubtful legality on both sides. In any case, St. Bernard's support of Innocent II, given largely on a moral judgment between the claimants, and later that of the emperor Lothair III decided the issue and were followed by a general recognition of Innocent II. The council, which counted among its members at least 500 bishops from all over the west and the Christian Levant, was styled "plenary" by the pope.

There were some 33 canons, many of them reaffirmations of previous conciliar decrees, but several had an importance and an influence greater than any in the first Lateran council. Thus while one canon reiterated the previous decree against clerical marriage, another declared all marriages of those in major orders and of professed monks, canons, lay brothers and nuns formally invalid—a decree that has remained substantially in force—while others fulminated against those who attacked a cleric or a monk and prohibited usury, tournaments and the study by monks of law and medicine. Canon 28 acknowledged by implication the right of a chapter to elect the bishop, and canon 23 is of interest as mentioning some of the characteristic heresies of the later 12th century: denial of the sacramental Eucharist, of infant baptism, of holy orders and of matrimony. The council probably lasted from April 4 to 17.

**Third Lateran Council (1179).**—This council was convoked by the ablest pope of the mid-12th century, the famous lawyer Roland Bandinelli, now Alexander III, who wished bishops from far and wide to witness the treaty he had made at Venice (1177) with Frederick I by which the emperor agreed to abandon his antipope and the church property he had seized. The council met in March 1179, and the 291 bishops present included those from the British Isles, Spain, Dalmatia, France, Germany, Denmark, Iceland, Hungary and the Levant, as well as abbots and envoys of princes. The council approved 27 *capitula*, of which the first established the principle of a two-thirds majority of the college of cardinals for a papal election and the third that candidates for the episcopacy must be of legitimate birth and 30 years old. The 27th was directed against the heretical Cathari (*q.v.*), who were anathematized, ostracized and refused Christian burial. Wandering robbers and vagabonds were also condemned, and Christians were authorized, with the bishop's permission, to take up arms against them not as heretics but as outlaws. The Waldenses (*q.v.*) sent representatives to the council, presumably to obtain some kind of papal sanction, and according to contemporary accounts they were kindly received by the pope but forbidden to preach.

**Fourth Lateran Council (1215).**—The first three Lateran councils were not convoked in direct imitation of the great councils of the early church. They were merely peaks in the long range of papal councils, noted at the time as "general" or "universal" and subsequently accorded ecumenical status by canonists and theologians. The case was other with the fourth Lateran council. This was the object of long deliberation and preparation on the part of Innocent III and was clearly envisaged by him as the continuation in the Europe of his day of the series of great councils of the past. It differed from them, however, in several particulars. First, the council was appointed, convoked and directed by the pope himself. Second, the church was now regarded as a great society, of which all members should in measure be represented. Third, Innocent's conception of his position *vis-à-vis* the emperor and other rulers led him to give them also a place. The broadening of its composition, however, in no way implied a wider extension of voting or consultative powers. Though little is known of the preparations or proceedings, it is clear from the fact that the general sessions of the council occupied only three days (Nov. 11, 20 and 30, 1215) that the fathers did no more than assent to the voluminous legislation proposed, presumably by select committees.

The summons was sent out to all bishops, abbots and ruling priors of Europe and the Latin east, to the heads of religious and military orders, and to princes and their representatives; some civic authorities and barons also were present. The purpose of

the assembly was twofold: the recovery of the Holy Land and the reform of the church. A list of 400 bishops survives, and there were probably numerous others present. Among the political business dealt with was the conveyance of the county of Toulouse to Simon de Montfort, the settlement of the disputed succession to the empire in favour of the young Frederick II as against Otto of Brunswick, and the excommunication of the English barons and Stephen Langton. Decision for a crusade was not taken.

The council passed various doctrinal and reforming decrees: a long profession of faith was directed against the errors of the Albigenses and Waldenses, though neither of these bodies was explicitly named; the existence of dual principles of good and evil was denied; the character of the Catholic priesthood was asserted; and the term transubstantiation was used of the eucharistic consecration. Unauthorized preaching was forbidden, the errors of Joachim of Fiore were condemned and the teaching of Peter Lombard on the Trinity approved. The practice of reprobation by the Greeks was reprobated and the primacy of Constantinople among the patriarchates denied. Vows of chastity and clerical celibacy were imposed by the decree *Omnis utriusque sexus*; impediments to marriage were reduced in number; a system of provincial chapters and visitations was imposed upon the Black Monks and the Augustinian canons. In addition numerous decrees were passed affecting the life and administration of the clergy and the reform of clerical and lay morality. Indeed, alike in its scope and its influence on subsequent practice, the fourth Lateran council has been surpassed in importance only by the Council of Trent in the history of the Western church.

**First Council of Lyons (1245).**—This council held its sessions on June 29, July 1, and 17, 1245, at the summons and under the direction of Pope Innocent IV. Its primary purpose was to secure the judgement and condemnation, followed by the excommunication and deposition of Frederick II, hence the 22 *capitula* of the council were legal and judicial, not dogmatic, in content. Only some 150 bishops were present, mainly from France and Spain, since the emperor excluded the Germans from attending.

**Second Council of Lyons (1274).**—This council held its six sessions between May 7 and July 17, 1274. It was summoned by Gregory X, with the threefold aim of ending the Greek schism, recovering the Holy Land and effecting a moral reform, but the last object occupied the most time in the council. Only some 200 western bishops were present, but the council was distinguished by some Eastern metropolitan bishops, among them Albertus Magnus and Bonaventura, who died at Lyons on July 15. The kings of the west, the Byzantine emperor and the catholicos of Armenia were invited, but the emperor did not attend. A creed was approved for the reunion of the churches which included reference to purgatory, the sacraments and the supremacy and primacy of the pope; this was accepted by the Byzantine emperor and the reunion, soon to be terminated by the Byzantines, was solemnly celebrated. The council also decreed that all patriarchs should take part in papal elections and that strict measures with the papal curia should ensure a more scrupulous election process. A number of abuses were suppressed, but the Carthusians and Austin hermits succeeded in escaping. Apart from the profession of faith there was no dogmatic decree.

**Council of Vienne (1311-12).**—Clement V convoked this council at the demand of Philip IV of France, and it held three sessions, the first on April 8, the second on April 24, and the third on May 6, 1312. All bishops in the west were invited and only some 100 were ordered to appear. The summons was made by the king of France, and in July 1309, San Giovanni in Laterano, though many others sent proxies, France and Italy concentrated for almost all but some. The primary aim of Philip IV was to secure a posthumous trial of Boniface VIII and the suppression of the Knights Templars. The trial did not occur, but the Templars, after long harassment, were condemned, mainly the pope, in an act of power of the pope on March 12, 1312. Another task of the council was to hear the complaints of the convents of moderate party of the Franciscans against the extremists or Spirituals, who stood for the observance of absolute material poverty. The moral strength of the Spirituals was impaired by the charges of heresy levelled against their principal leader, Pierre Olivi, and the council decided in favour of

moderate poverty (the so-called *usus pauper*) against Olivi. His name was not mentioned in the condemnation of his views. The pope, who had not been present at the later sessions, gave the decisive force of law by his approval.

The councils of the 12th and 13th centuries are of a pattern that of a gathering of bishops and other prelates (later, notables in a great body summoned presided over by the pope, and the series shows a growing tendency seen also in the history of the Roman Curia during the 14th century, the representative and deliberative function of the council to be reduced to a mere assent, at least in the sessions. These councils, in other words, reflected the monarchic, unitary, autocratic development in papal practice that reached its limit in the pontificate of Boniface VIII.

Yet concurrently with the Aristotelian postulate that all must in the end be reduced to unity there was the characteristic medieval doctrine that society, and in particular the church society, was a corporate body whose head was a representative rather than a ruler and which could achieve its end only by acting as a body and could correct or depose any representative who failed in his duty. This doctrine was applied by the pope both to the college of cardinals and to the totality of the church, as seen in action in a general council. The first application of this theory to practical politics followed upon the election of Pope Celestine V (1294) and the subsequent conflict between pope and the king of France. Philip IV appealed to a general council against Boniface VIII and threatened his deposition. 30 years later, Marsiglio of Padua and William of Ockham in different ways looked to the university of the faithful as a council representing them, as a remedy against papal abuse, and specifically against the alleged heresy of John XXII. Therefore, the contested election of 1378 left the church in a state of confusion, and two popes and all efforts to restore unity had failed, a general council, which *ex hypothesi* would be able to judge and if necessary depose a pope, came to be regarded as the only hope for the church. In these circumstances a council would be more powerful as an organ of ecclesiastical government than hitherto been suggested.

**Council of Pisa (1409).**—It was after 30 years of debate and when the powers and advantages of a general council had been debated on all sides, that a group of cardinals of both obediences summoned a council to meet at Pisa in 1409. This meeting has never been admitted by canonists or theologians as a general council, was well attended, it proceeded to depose the two pontiffs and to elect a third, Alexander V, Western Church was therefore divided into three parties.

**Council of Constance (1414-18).**—The effort of Pisa had not been wholly in vain, for it had shown that a council rallied the forces desirous of unity. The emperor Sigismund therefore, summoned a council to Constance, which was followed by that of the antipope John XXIII of Alexander V. The council met in Nov. 1414. Not only had such an assembly of ecclesiastics been gathered, but besides some 200 bishops and 100 abbots at least 100 theologians and proctors of all kinds were there. Very great rivalries resulted in an essential change of the system by which the members were organized in four blocks: French, Italian, English, German and French—each of which the members were organized in four blocks. Each nation had equal weight, while the college of cardinals had no vote and later the Spanish nation a sixth. After a long session John XXIII fled from Constance and the council declared its authority, declared in the decree *Sacrosancti* that it drew its powers immediately from Christ and that even the pope was subject to it. It then proceeded to negotiate the withdrawal of the other two papal claimants. In the process it anathematized the doctrines of Wycliffe and Huss and executed the latter and his friend Jerome of Prague proceeded to frame some decrees of reform, of which the most important was the decree *Frequens* of Oct. 9, 1417, which made general councils a permanent institution in the church. It then elected Martin V, thus at last restoring unity to the church.

dispensations, taxation, patronage, etc.—were widely denounced as hindrances to fruitful episcopal residence, as also were hindrances from the secular arm. Not much time was allowed for the discussion of all these points, and the decrees passed were far from satisfying those who wanted treatment of the diseases of plurality of benefices and nonresidence far more drastic than the touching up of old canonical rules that could be freely circumvented in practice.

The papal legates and the Italian bishops had all along disliked the location at Trent, so accessible to imperial influence. Plans and negotiations for a removal south had been unceasing, especially after the emperor's war against the Lutherans started in the summer of 1546, but all these had broken down on the emperor's refusal. The transference to Bologna was thus the fulfillment of a long-felt Italian desire. It was made suddenly by a majority decree, on March 11, 1547, at the legates' prompting, but without the knowledge of the pope, on a plausible but not wholly convincing plea based on the fact that an epidemic had broken out in Trent. It proved self-defeating. The 13 opponents of the decree remained behind and subsequently received imperial orders not to move; while, unable to persuade Paul III to reverse the council's action, Charles V, whose victory over the Protestant princes at Mühlberg on April 24 gave him at last his supremacy in Germany at the very moment when the council had left German soil, delivered formal protests of nonrecognition of the council of Bologna at Bologna itself and at Rome in Jan. 1548. This was followed up in the summer by the *Interim* settlement in Germany. Not even increased French support for Bologna could outweigh this. The council was made impotent. There were many valuable discussions on matters later settled at Trent, but no decrees could be passed. Not until Sept. 1549, however, shortly before his death, did Paul III allow the council at Bologna to disperse.

His successor, Julius III, showed unexpected flexibility in recalling the council to Trent, where it reassembled in April 1551. There seemed now a better understanding between pope and emperor, and it was hoped that with the attendance of about a dozen German bishops (only one had previously appeared other than the cardinal of Trent), including the three ecclesiastical electors, the emperor's policy toward the German Protestants might still be made to bear fruit. These hopes were shattered by the rejection of the council by the French; the intransigence of the legate Marcello Cardinal Crescenzo toward Spanish and other efforts for effective reform; and finally by the impossibility of finding common ground for talks with the Protestant delegations, which had actually arrived from Saxony, Württemberg and elsewhere, and whose ministers claimed equality of status. Nevertheless the council, continuing its former doctrinal program, passed decrees on the sacraments of the Eucharist, penance and extreme unction together with some minor reforms. In April 1552 it was suspended owing to the outbreak of war in Italy and the revolt in Germany which overthrew Charles V's supremacy, both disturbances promoted by the French. The elector Maurice of Saxony, who had allied himself with France, marched southward by way of Innsbruck. The emperor, taken by surprise, fled, and the council, fearing for its safety, decreed its own suspension.

When the council reassembled ten years later under Pius IV in Jan. 1562, the demand for it came from France, newly troubled by the Calvinist movement. The treaty of Câteau-Cambrésis (1559) had restored international peace; Charles V was dead, the German and Spanish crowns separated, and Germany pacified by the settlement of Augsburg (1555). The third assembly at Trent was more widely representative than its predecessors, and numbers rose to about 250 against the previous 70 or 80. Nonetheless, the German bishops, as well as the Protestants, stayed away, and in England the invitation was not even published. The Italian majority was rather more coherent and Roman control more systematic. The papal legates' exclusive right of proposition was now specifically laid down and, though constantly challenged by the French and Spaniards, was maintained. It was used to make it clear that the council was a continuation—whereas the French and Ferdinand I wanted a new start—and also (as previously) to keep a firm grip on both doctrinal and reform proposals.

In spite of the efforts of Ferdinand, who, still hoping for the return of the Protestants, wished to defer the discussion of dogmatic issues, the doctrinal program was completed by decrees on the Mass, holy orders and matrimony. Reform proposals involving radical changes in ritual and discipline, and including permission for clerical marriage and lay communion under both kinds, came from the French and imperialists, both still hoping to pave the way toward general religious agreement by concessions. But most of these were resisted in Rome as was also the renewed demand for the residence of bishops to be proclaimed *de jure divino* as the only way to the restoration of episcopal efficiency. A vote taken on April 20, 1562, showed the strength of the *ius divinum* party. It so annoyed the pope that the two principal legates, Ercole di Gonzaga, cardinal of Mantua, and Cardinal Seripando, were nearly recalled. Worse was to follow, however, when in the discussions on holy orders, the same party—comprising bishops of all nationalities present—pressed for a statement that episcopal jurisdiction came to each bishop direct from God and consequently not mediately through the pope. Determined to prevent this, the Roman authorities attempted to insert into the decree the definition by the Council of Florence of the papal universal episcopate, unacceptable to both French and Spaniards. Months of negotiation did not succeed in breaking the deadlock, which held up the council's work and even threatened its collapse.

Eventually, the deaths of Cardinals Gonzaga and Seripando opened the way for their replacement by the able Cardinal Giovanni Morone, whose skilled diplomacy secured the surrender of the extremists on both sides and general agreement to a plain statement that bishops were placed by the Holy Ghost to rule the church (Acts xx, 28).

Mutual concessions were also made on reform principles. In return for the safeguarding of curial rights, Rome would agree to as searching a reform as possible. Only the Spanish ambassador stood out, in principle, against the general *détente* acquiesced in by the emperor and the cardinal of Lorraine, leader of the French.

The effective reforms of the Council of Trent, which gradually restored the pastoral efficiency of the Roman Catholic Church, were the work of the final two sessions. They represented as it were, the middle-of-the-road conservative Catholic reform ideas, giving a new deal to bishops (empowering them, however, in many cases to act as representatives of Rome), laying down a new code for the religious orders and including the decree ordering the establishment of diocesan seminaries for the education of intending clerics. There were, however, none of the radical changes desired by the French and the imperialists (under both Charles V and Ferdinand I) for the appeasement and eventual hoped-for reduction of Protestantism, nor was any diminution allowed in principle of the rights of the Roman see or the Roman curia, nor were the more rigorous Spanish demands met. An ambitious scheme for the "reformation of princes" had perforce to be abandoned in favour of a simple admonition to rulers to respect the rights of the church. The council handed over to the pope its unfinished tasks of drawing up an index of forbidden books and reforming catechism, missal and breviary. It concluded harmoniously on Dec. 4, 1563, and its decrees were confirmed by Pius IV on Jan. 26, 1564.

**First Vatican Council (1869-70).**—An interval of more than three centuries separated the Council of Trent from that of the Vatican. Never before had so long a period elapsed without a meeting of the bishops of the church. Many circumstances had brought this about, not least the work of Trent and the popes of the Counter-Reformation, which had given to the church and the papacy a program, a directive power and a centralized organization adapted to the needs and sentiment of the modern world. Moreover, though the papacy had emerged with renewed strength in those parts of Europe and the rest of the world that had not been lost to the Roman Church, the growth of national spirit and the claims of the secular ruler, which had so greatly influenced the Reformation, were equally influential in the Catholic monarchies of Spain, France and Austria, in all of which papal authority though acknowledged as paramount, was in practice neutralized.

by the limitations set by old customs or new concordats.

But whereas in Spain and Austria the obstructive forces were almost wholly political or social, in France under Louis XIV the ancient claims of the Gallican church were reasserted more precisely in the realm of theology and political thought, with the doctrine, based on the decrees of the Council of Constance, that a general council was superior to the pope and that papal pronouncements required the assent of the church to acquire binding force. This attitude of the most powerful Catholic nation was enough to prevent any thought of a general council, and it weakened only when Europe was swept by the waves of rationalism and secularism, culminating in the French Revolution. When that great earthquake and the tidal wave of Napoleon that followed were over, a great religious revival took place, but the papacy found itself at issue with foes both domestic and foreign. Within the church, a large section of the older clergy, especially in France and Germany, was imbued with the Gallican or "Josephist" ideas of the old regime, while the largely antireligious forces of liberalism and communism and the new sciences of nature and documentary criticism threatened to penetrate and to overthrow the church. In addition, nationalist sentiment in Italy made the "Roman question" a burning issue.

It was with this background that the long-lived, well-loved and much-enduring Pius IX, whose pontificate, the longest in the history of the church (1846-78), witnessed the Italian *risorgimento* and the disappearance of the States of the Church, decided in 1864 to convoke a council "to discover the necessary remedies against the many evils which oppress the church." The bull of convocation was dated June 29, 1868. At the suggestion of Bishop K. J. Hefele, the historian of the councils, two procedural changes were made in advance, as lessons from Trent: business was prepared by commissions before the council met, and the right of proposing subjects for discussion was reserved to the pope.

Meanwhile the attention of Europe was concentrated on two topics: the relation of the church with the modern state, and the teaching authority of the pope. The first topic, made immediate by the reactionary outlook of Austria, the secularist government of Bismarck and the new liberalism in Italy and France, was not in fact dealt with by the council. The second had become a storm-centre, violent if somewhat artificially exploited, between the semi-Gallicans of France and the heirs of Febronianism and Josephinism in Germany and Austria on the one hand, and the Ultramontanes who favoured centralization in Rome and wished for a speedy and certain doctrinal pronouncement on every controversial topic on the other. Papal infallibility, though so much to the fore both before, during and after the council, was, on the purely theological level, not a major topic of controversy. Almost all the bishops present at the council, as private theologians, held the substance of the teaching that was subsequently defined. They opposed the definition, partly from motives and habits of mind too deep to analyze, exacerbated to some extent by extremists on the other side; partly because they feared its consequences in provoking hostility to the church or discouraging those outside; and partly because they feared the lengths to which their opponents might go.

In all these matters there was mutual distrust and exasperation owing to partisan propaganda on both sides. But without exception all Catholic bishops were devoted both to the papacy as an institution and to the reigning pope, and in fact not a single bishop went into schism. The fears and the enthusiasms of that day have passed, but they may be recaptured in part by anyone who reads the letters of Janus and Quirinus (both the work of Ignaz von Döllinger) on the one side, and of Louis Veuillot in the French Catholic liberal paper the *Univers* on the other.

The council met on Dec. 8, 1869, and from first to last a total of 774 bishops (nearly three-quarters of the total number of bishops in the universal church) took part. In addition representative superiors from the religious orders were summoned, and each bishop had his theologian. Sovereigns of states were not invited, as they had been at Trent, and despite threats no government demanded representation, and all disclaimed any intention of intervening. The procedure was as follows. All suggestions

previously sent up by bishops and others to Rome were sifted by papal commissions, which prepared drafts (*schemata*) on the various subjects. The council itself elected four "deputations" to deal with specified topics: faith, discipline, regulars and eastern missions. The *schemata*, duly printed, were then debated in general congregations and referred back to the relevant deputations, which made what amendments they thought fit. When finally approved the formal decision was voted on as a whole and then for a second time at a public session presided over by the pope, who then promulgated the decree. The program was far too ambitious and the members too loquacious for the achievement of more than a small part of the agenda.

The first four months (Dec. 8-April 24) were occupied with the decree of faith, and resulted in the first dogmatic decree on the existence of God and the capacity of the human intelligence to know this; the necessity of divine revelation; the nature of faith; and the relation between faith and knowledge. Valuable for theologians and apologists, this seemed a small and not very practical result of so many weeks' discussion, while the burning questions of the day were shelved.

Although papal infallibility was not the professed topic of conciliar action and did not appear on the original *schema*, the alignment of parties, infallibilists and inopportunistes, had taken place at once, with lobbying and intrigues on both sides, and it had already become evident that the infallibilists were greatly in the majority. Among them V. A. I. Dechamps (Malines), I. Senestrey (Ratisbon), K. Martin (Paderborn) and H. E. Manning (Westminster) were eminent. The leaders of the inopportunistes were G. Darboy (Paris), F. A. P. Dupanloup (Orléans), J. O. Rauscher (Vienna), F. Schwarzenberg (Prague), L. Hayald (Kalocsa, Hung.), J. Simor (Esztergom), K. J. Hefele (Rothenburg), W. E. Ketteler (Mainz), P. Kenrick (St. Louis) and D. Moriarty (Kerry). While the former group chafed at the delays, the latter feared an attempt to define by acclamation without a debate and pleaded the necessity of moral unanimity for a definition.

The documents and debates of the council were in theory secret, but leakages were constant and garbled versions were available for the diplomats and the correspondents who were covering the council. Thomas Mozley's very inaccurate dispatches to the *Times* in London and the more accurate but biased reports which Johannes Friedrich and Lord Acton passed on to Döllinger, for his letters to the Augsburg *Allgemeine Zeitung*, embittered minds abroad, while the atmosphere of intrigue and campaign, reflected in the caballings and even the social life of Rome in the salons of the *matres ecclesiae*, gave the council a repute which the debates and the conduct of the bishops as a whole did not deserve.

The plea of the minority, that to raise the infallibility question would be to advertise the divisions among Catholics, invited the retort that to smother the issue would be to admit the division as irremediable. Meanwhile the pope, who in the early weeks of the council had expressed his desire to leave all initiative and decision to the council, came out openly, from January onward, in favour of a definition, and on March 6 the public announcement was made that infallibility was to come up as an addition to the original *schema de ecclesia* ("of the church"), which originally contained the questions of papal primacy and jurisdiction only. These latter were debated on June 6-14 and defined as the bestowal by Christ on the pope, as the true successor of St. Peter, of

an ordinary immediate jurisdiction over the whole church and over every particular church, but without prejudice to the ordinary and immediate power of episcopal jurisdiction wielded by the bishops set by the Holy Spirit in place of the apostles.

The council forebore to elucidate any further the source of episcopal jurisdiction.

On the precise point of infallibility two long debates took place, the first (May 13-June 6) on the desirability or otherwise of the definition, the second (June 15-July 4) on the actual text of the decree. Both debates were cut short, the first by an agreed closure, the second by an agreed withdrawal of speakers in view of the heat and discomfort of Rome in July, and (at last) of the threatening international situation. At a vote on the decree

(called *Pastor aeternus*) on July 16, out of 552 present, 88 voted *non placet* ("no") and some 30 more desired qualifications of the decree (actually, 62 voted conditionally, but half of them wished for a more extreme definition); these represented the hard core of the 200 odd who at the beginning of the year had expressed their opposition to any definition. The minority were for recording their votes at the public session, but Dupanloup overbore the decision and instead they left Rome before the voting took place. The final session on July 18 was accompanied by a violent thunderstorm; 533 voted *placet* ("aye") and 2 *non placet*. The pope then promulgated the solemn definition. On the following day war was declared between France and Prussia and on Sept. 20 the Italian armies captured Rome. In due course all the bishops of the minority accepted the definition, but in southern Germany and Switzerland the schismatical church of the Old Catholics (*q.v.*) was set up, with governmental support in both cases.

The infallibility decree was couched in terms more moderate than many of the minority had feared. During the debate the gap had been narrowed between the two parties and almost all the minority would have accepted a form of words such as "using the counsel and seeking the help of the universal church" to qualify the papal infallibility, while on the other hand no attempt had been made to satisfy the wide extension desired by the extreme Ultramontanes. The decree limited the gift of infallibility to the occasions when the pope, speaking *ex cathedra* as pastor of the universal church, defines a doctrine concerning faith and morals, and the council declared this guarantee to be equivalent to that possessed by the church itself. As no previous decree had declared the exact limits of the infallibility enjoyed by the church it was open to theologians to restrict the papal power to the narrowest limits consistent with the words of the decree.

The Vatican council, though in many ways resembling that of Trent, was in others without precedent. The railway and the steamship had permitted a greater number of the bishops of the world to be present than at any other previous council, and representatives did in fact come from every part of the world where the Roman Church had obtained a foothold. In addition, the electric telegraph and the technique of journalism allowed the whole world to follow its fortunes and comment upon its personalities, even if the oath of secrecy led to many inaccuracies and misrepresentations. As regards the many charges of unfair dealing that have been made, no one who reads the reports of the debates and other literature will deny that freedom of speech was enjoyed, and in the matter of intrigue and propaganda there is nothing to choose between the two parties.

Two important grievances of the minority deserve fuller attention. The one was the direct influence of the pope, who certainly threw all the weight of his personal authority on the side of the majority, even though it was the influence of a revered father in Christ, not of a ruthless autocrat. The second was the undue weight given to a reputedly obscurantist section by the presence of a great number of Italian bishops from small sees.

Both these circumstances were regrettable, but in the broad view it would seem clear that the movement in favour of the definition was both in origin and in strength independent of any action of the pope, and that it was supported throughout the Catholic world by a body of theological and popular support sufficient to ensure a large majority in any great assembly. Moreover, the excitement and partisan feeling in the council were largely factitious, the result of 20 years of public debate. It is probable that few of the minority would have been willing at any time to subscribe to a negation of the decree. The circumstances of the time made of the council a focus of controversy greater even than Trent.

For another discussion of the deliberations of this council, and comments on the results of the decree *Pastor aeternus*, see VATICAN COUNCILS. Other aspects are discussed in PIUS; INFALLIBILITY; GALLICANISM; ULTRAMONTANISM.

**Second Vatican Council (1962-65).**—For this, see VATICAN COUNCILS.

### CONCILIAR THEORY

The ecumenical council as it has developed during the centuries

has been affected both by historical circumstances and by the theological teaching of the Roman Catholic Church. It is canonically defined as an assembly of bishops and others, convoked by the pope and presided over by him, to formulate decisions on matters of faith and discipline. A constant feature of its history is the belief that the testimony of a large and representative body of bishops of the universal church, each having apostolic succession and engaged in an apostolic office within a single communion of authority, will be a sure witness to the Christian faith, not only as a majority opinion, but in virtue of Christ's promise of indefectibility to his church.

In the centuries after Constantine when the church was, or was still regarded as, coterminous with the Roman empire, the councils were convened by the emperor and their decisions passed into imperial law, though from the beginning the privileged position of the bishop of Rome was acknowledged. When the political severance of the west was finally effected by Charlemagne it seemed likely that the western emperor might claim the position of the eastern, but the disorder of western Europe prevented this, and one of the results of the papal-imperial controversy of the 11th century was to leave the papacy in undisputed possession of spiritual jurisdiction. Henceforward for three centuries the councils were primarily courts of record, summoned to give assent to political, disciplinary or doctrinal decisions of Rome.

The procedural impasse and the bankruptcy of council during the Great Schism allowed the "corporative" school of canonists and publicists to propose a program in which a council "represented" the universal church, with the pope as its delegated executive, in some such way as the general chapter and master-general stood to the members of certain religious orders. After some decades of popularity this view, which lacked theological and papal support, lost its appeal and the monarchical papacy reasserted its claims, though the "conciliar theory" remained in favour largely for political reasons, with the French monarchy and the Gallican church. In the authoritarian, controversial atmosphere of the 16th century, the Council of Trent was fully "papal" and "Catholic," but a spirit of debate and party appeared that was a new thing in western councils. The Vatican council resembled Trent, but the venue of the council, the topics debated and the personality of Pius IX combined to make papal control more constant and pervasive.

It has often been urged that the definition of papal infallibility in 1870 ended the need for and would in fact end the series of councils. Neither history nor theology support this view. Several of the medieval councils did little if anything more than accept and record a papal decision, while on the other hand a council still remains a normal and under some circumstances the best means for a pope to use in order to assure himself of the traditional teaching of the church on a disputed point of doctrine, or to receive advice on matters of high policy concerning the unity of all Christians and the spread of the faith. Pope John XXIII recognized this fact when, in 1959, he announced his intention of calling an ecumenical council on the unity of the church. (M. D. K.)

(W. O. C.; H. O. E.; M. D. K.)

**COUNCIL BLUFFS**, a city of southwestern Iowa, U.S., and seat of Pottawattamie county, is located on the east side of the Missouri river across from Omaha, Neb. The business district is

situated on the bottoms along the foot of the bluffs about 3 mi. back from the river.

While Council Bluffs was founded by the Mormons, they were not the first to visit the area. Lewis and Clark passed there on their expedition to the far west in 1804 and held a council nearby with the Indians at a place they called Council Hill or Council Bluff. This name was later applied to the area in general on both sides of the river.

A settlement was started by the Mormons on their way west in 1846 after they had been driven from Illinois. At first it was called Miller's Hollow, but in 1848 the name was changed to Kanesville in honour of Col. Thomas Leiper Kane who had befriended them. During the next few years this was a focal point for Mormons going to Utah; many California gold seekers also came this way. By 1853 the Mormon influence had waned, the name was changed to Council Bluffs and the town, which was already an important outfitting point for the west, was incorporated by the Iowa legislature. Six years later Abraham Lincoln visited Council Bluffs and was so impressed that he designated the city as the eastern terminus of the Union Pacific railroad.

Since then Council Bluffs has been an important trade and transportation centre. It is served by several major railroads and has one of the largest railway mail terminals in the country. Large grain elevators and extensive greenhouses are located there and its industries include the production of agricultural implements, batteries, railroad equipment and radio parts. The council-manager type of city government was adopted in 1950. The population in 1960 was 55,641. For comparative population figures see table in IOWA: Population. (F. W. A.)

**COUNSEL AND COUNSELOR:** see LEGAL PROFESSION.

**COUNT** (Lat. *comes*; Fr. *comte*; It. *conte*; Sp. and Port. *conde*; Ger. *Graf*; Pol. *hrabia*; Russ. *graf*), a European title, in the early middle ages one of certain royal officials, later one of nobility. For the English equivalent see EARL.

**The Roman Comes.**—Under the early Roman empire persons who accompanied the emperor on his travels were called his "companions" (*comites Augusti*), but *comes* was not an official title. Constantine I, however, in the 4th century A.D. created a regular order of "companions," graded in three classes. The title, which was held during the emperor's pleasure, was bestowed both on senators and on those of lower station; later the first grade automatically carried senatorial rank. It was naturally given first and foremost to members of the imperial court (*comitatus*), including those sent out on special missions, but it was soon extended to others as an honorific distinction. In its primary sense the title (first grade) was held by the members of the imperial council (*comites consistoriani*) and by the higher civilian ministers and military officers of the court. In some cases the title *comes* superseded the original designation of the minister or officer. Thus the director of the mints, mines and money taxes came to be known as the *comes sacrarum largitionum*, the director of the imperial domains as the *comes rei privatae*, and the commander of the corps of officer cadets as the *comes domesticorum*; and in the 5th century the title was extended to lesser offices such as the director of the imperial stables or *comes stabuli*, the original of the medieval constable (*q.v.*). Outside the palace the original of the medieval constable (*q.v.*). Outside the palace Constantine used his *comites* to preside at church councils on his behalf and as special commissioners to supervise the dioceses of the empire and receive complaints against the provincial governors; these *comites provinciarum* did not survive after the reign of Constantine except for the *comes Orientis*, who replaced the vicar of the diocese of the Orient. "Military companions" (*comites rei militaris*) were used to command detachments of the field army, and several of these commands (*e.g.*, that of the *comes Africae*) became permanent. The second and third grades of the order were widely bestowed on lesser officials and private persons, and their value had by the 5th century become debased. (A. H. M. J.)

**The Frankish Officials.**—In the Germanic kingdoms that succeeded the Roman empire in the west the title *comes* was freely employed. The Ostrogothic king Theodoric gave it to those whom he placed at the head of the various towns. These Ostrogothic

*comites* were civil judges and decided quarrels between Goths and Roman citizens, with the help of Roman jurists.

The title was likewise taken over by the Visigoths and by the Franks. In the *Historia Francorum* of Gregory of Tours, covering the early Merovingian period, the *comes* appears as city commander and, as with the Goths, as a judge even in criminal cases. Gregory already speaks of the area of jurisdiction of a *comes* as *comitatus* (countship, county), but Frankish royal documents of the 7th and 8th centuries usually give the name *pagus* to those districts which corresponded in area to the ancient city districts. The Frankish title *gräfo*, meanwhile, etymologically linked with Ger. *rafen* ("gather"), at first denoted the royal official who collected the fines imposed by the popular court: one-third of the fine went to the *gräfo* as his pay. In the edict of Chilperic (*c.* A.D. 570) the *gräfo* is still a subordinate official who may not come to court until called by the *Rachinburgen* (jurors), and in royal documents after 669 he is still below the rank of *comes*, though sometimes holding a similar position. It is not precisely known when the *gräfo* replaced the *Thungin* as president of the court. It was probably not until the 8th century, under King Pepin, that *comes* and *gräfo* became equal.

The capitularies of Charlemagne describe the legal position of the *comes* much as Gregory of Tours does. They contain many regulations on the conduct of recruitment and preparation for war by the *comes* and also show how the officials known as *centenarii* had concurrent jurisdiction with the *comites*. The older view that each countship was divided into several *centenae* (hundreds) has been superseded by modern research. Rather the *centenae* are now regarded as the organization of the Frankish occupation forces from Charles Martel's time onward, especially in Swabia and Franconia. In Carolingian documents likewise the district in which a count commands is called *pagus*, though from 775 the name *comitatus* also occurs. (Later, in the documents of German kings such as Conrad I and Otto the Great a double designation often occurs: "in pago [name] et in comitatu [of such and such a count]"; and this formula prevails in German royal documents down to 1100.) The view that each count commanded in a closed district was championed above all by those researchers whose main concern was with historical geography, but it has been established that, especially, wasteland and woods lay outside the divisions into countships. The Franks made these divisions in Saxony and in Bavaria and after 772 introduced them into Italy as well, but in some regions (*e.g.*, in Thuringia) the system seems not to have been introduced. It was partially implemented in the Slav territories conquered by the Carolingians in the south-east, as also in the later march of Meissen, but not in Bohemia or in lands east of the Elbe river.

**Feudalization.**—The merging of the office of count into the feudal system (see FEUDALISM) seems to have proceeded very slowly. Though Carolingian capitularies do sometimes state that a count should swear an oath of fealty, the office of count, down to 900, is described either as *honor* or as *ministerium* (function), never as *beneficium* (grant). In Italy, meanwhile, there is occasional mention of possessions belonging to the countship.

In France, counts became vassals of dukes by 900 at the latest; the counts of Flanders and Toulouse, however, were considered as equal in rank to dukes. As the process of feudalization continued, the counts moreover tended to lose their official character and to become the hereditary lords of little territories. In France this development is already discernible in the 11th century, and with it there grew up the practice of applying the title of count very loosely. By the 12th century any lord of moderate status might style himself count, no less than the great feudatories of Flanders and Toulouse; and even in the 13th, when the organization of the French kingdom became more stable, the title might mean much or comparatively little.

In Germany, though the title of count had become hereditary in most cases as early as the 10th century, the counts retained something of an official character rather longer than in France. In the 12th century, however, apparently by the emperor Frederick I Barbarossa, they were given authority to maintain the public peace in the district under their control—an authority which

up to 1100 had belonged to the dukes. Thenceforward the term countship signified the territory within which the count had powers of life and death.

Already in the 11th century, several countships in Germany had been acquired by bishops (e.g., the bishops of Brixen); and in the 1160s the bishop of Würzburg, as the holder of numerous countships, began to claim the title of duke of Franconia, which was confirmed in 1168 by Frederick Barbarossa. The bishops often handed on to laymen the countships granted to them by the king.

From the beginning of the 12th century, moreover, a number of counts appear in western Germany taking their titles simply from the castles held by them—with no apparent connection with any official status. In Frederick Barbarossa's time certain free-men of the higher class, such as *Vögte* or "advocates," began to style themselves as counts. In the 13th and 14th centuries there are instances of new countships received as fiefs from dukes.

For other developments of the countship, especially important in Germany, see LANDGRAVE; PALATINE. For the "free countship" of Burgundy see FRANCHE-COMTÉ.

In northern Italy the Carolingian rulers had been represented by a count palatine at Pavia from the early years of the 9th century. He in turn had appointed viscounts to assist him. With the decay of the royal authority a system of countships based on cities had grown up. Several cases are found of a number of countships in the hands of a single margrave (for example in the march of Tuscany, under the margraves of Canossa, and in the march of Este), but it cannot be stated positively that any counts became dependent on dukes (the ducal title was rare in northern Italy). The 10th century, however, saw many countships beginning to pass into the hands of bishops, who were less ready in Italy than in Germany to pass them on to laymen. It was from among the members of the judiciary appointed by the bishops in their countships that the consuls of the communes were largely recruited (see COMMUNE [MEDIEVAL]). The rise of the communes meant the end of the countship's former significance. In southern Italy the countship was established by the Normans in the 11th century.

In Spain the countship developed under Visigothic influence in the kingdom of Asturias-León and under Frankish influence in Catalonia and in the country immediately south of the Pyrenees. By uniting the Catalan countships, the counts of Barcelona (q.v.) made themselves into practically sovereign princes, comparable at least to the counts of Flanders and Toulouse; and the Carolingian countship of Aragon was the nucleus of the kingdom of that name. The countship of Castile, on the other hand, from which the kingdom of Castile emerged, was originally a frontier district of the kingdom of Asturias-León. In the latter kingdom the official character of the counts as district administrators appointed by the kings was preserved till the end of the 11th century, when the principle of hereditary lordships of one sort or another began to prevail.

In Hungary the office of count was adopted in the 11th century, the designation of *comitat* being given to the castellany and that of *comes* to the dignitary previously called the *iszpan* (from Slavonic *zupan*). On the Hungarian border special countships arose (e.g., Forchtenstein and Güssing in the modern Burgenland), in which the petty nobility otherwise so typical of Hungary was absent.

**Counts as Nobles in the Modern State.**—The reassertion of royal authority over the feudatories, which took place at different times in the different kingdoms and led to the formation of centralized states of the modern type, meant that the counts as such lost their political authority, though they retained their privileges as members of the nobility.

In France the development of the system of royal *bailliages* from the beginning of the 13th century onward served to restrict the counts' rights of legislation, judiciary and private war. Next the counts lost the rights of minting money (in the 16th century). Moreover, the gradual reunion of the great fiefs to the French crown, after which they were granted only in apanage (the territory itself being administered as a province of the kingdom), meant that the only countships surviving as fiefs till the end of

the *ancien régime* were little properties whose holders in many cases had had them "erected into countships" within recent memory so as to enter the estate of the nobility.

The French Revolution reduced the counts to the level of "citizens." Napoleon, however, by his decree of March 1, 1808, revived the title, which was assigned *ex officio* to ministers, senators and life councilors of state, to the president of the Corps Législatif and to archbishops. It had no territorial significance, but was made hereditary in order of primogeniture (through nephews in the case of archbishops). Further creations of a similar type followed under the later monarchies.

In Germany the structure of the Holy Roman empire made the reduction of feudalism a slower process than in France. Distinctions, however, came to be made between (1) counts who became princes of the empire (*Reichsfürsten*); (2) counts of the empire (*Reichsgrafen*) who were also members of the college of counts (*Grafenkollegium*); and (3) other counts.

When Frederick Barbarossa organized the estate of princes in the 1180s, princely rank was accorded only to immediate vassals of the emperor. At first this meant that, apart from such counts as were equivalent to dukes (namely landgraves, margraves and counts palatine), the only princely count was the count of Anhalt. The first countship thereafter to be "raised to princely rank" (*gefürstete*) was that of Tirol—an elevation due to the fact that the counts of Tirol were also, from 1286 to 1335, dukes of Carinthia. A princely count had his own personal vote in the college of princes, part of the diet of the empire.

Elevation to the rank of count of the empire was rare in the 14th, 15th and 16th centuries. The college of counts was established as a component of the council of princes in the 16th century, but the counts could vote only collectively, by benches (*Grafenbänke*). These benches at first numbered only two, the Swabian and the Wetterau or Veteran, but in the 1650s two more were added, the Westphalian and the Franconian. Meanwhile the emperor Ferdinand II had tried to counteract the Protestant influence in the college by raising a considerable number of Catholic nobles to the rank of count. These elevations were recognized, but from 1648 entry into the college was restricted to those who levied taxes on territorial countships. Thenceforward the title of *Reichsgraf* could be bestowed as the emperor thought fit, but the recipient would not automatically enjoy the full rights of members of the college.

After the dissolution of the Holy Roman empire the counts of the empire were mediatized; i.e., made subject to the sovereigns of the various German states instead of being "immediate" subjects of the emperor alone. The federal diet, in 1829, however, recognized their right to the special style of *Erlaucht* ("Illustrious Highness").

In Italy the title of count was quite liberally bestowed by the popes and other sovereigns of the peninsula. In Spain it was not conferred with more reserve. In Russia, where it was not introduced till Peter the Great's time, it came to be given usually to officials of a certain rank in the government service. In Poland there were no counts before the partitions, when the title was introduced by the Russians, Austrians and Prussians.

**COUNTERFEIT MONEY.** The imitation of money for gain has probably been practised by unscrupulous persons ever since money came into use. The study of counterfeiting, as seen from the point of view of suppression and prevention, is complicated and its aspects vary according to whether it concerns paper or metal currency. Counterfeiting is complicated because it can be accomplished only in successive stages: first the counterfeit must be produced by printing, striking or casting; then it must be passed in a clever and underhand way as genuine currency. All this means that it will be some time before the counterfeiter can realize any profit. It is an offense that requires a certain amount of technical and artistic ability and one for which the legal punishment is severe.

Base coin may be cast, struck or produced by a plating process. The casting of coin requires the use of molds made of gypsum plaster, pulverized earth, cement, iron or wood. The striking of coin is effected by means of engraved dies.

Bank notes may be drawn or traced by hand. Such notes are among the least deceptive counterfeits and cannot be mass-produced by this method. The reproduction of bank notes by printing requires the use of metal frames, called forms, in which set type or other matter from which an impression is to be made is secured. The counterfeiter may utilize typography or letterpress printing (line cuts and half tone); planography (offset, lithography); or intaglio (rotogravure, copperplate engraving).

The terms counterfeiting and forgery are often used without distinction, but in the case of paper currency and coin a differentiation has to be made. Counterfeiting denotes fraudulent imitation of a genuine note or coin but forgery implies (1) falsification of a genuine note by alterations that will make it appear to be a note of higher denomination, or (2) debasement of a coin by clipping or some other process with the intention of palming it off as genuine money.

In the case of gold pieces there is a third form of imitation known as illegal manufacture. This practice is based upon the fact that the market value of minted gold is higher than that of gold bullion. If such gold pieces are no longer legal tender, the coiner does not commit the crime of counterfeiting in the legal sense nor, if the gold content of such coins is in conformity with the statutory fineness, can he easily be accused of fraud. Nevertheless these private coiners are liable to criminal prosecution on the charge of illegal use of official marks.

In the practice of counterfeiting there are two kinds of production, individual and collective or industrial. In the case of one-man production the counterfeiter will often be anything but an expert in graphic arts and may merely have consulted some literature on the technique of engraving and photogravure and have acquired a superficial knowledge of them. Yet the fact cannot be denied that he often succeeds in passing counterfeit notes of poor workmanship. The public at large is generally very careless in the handling of money and most people accept notes and coins without so much as casting a glance at them. There are cases of amateurs who have succeeded in making almost perfect counterfeits, but it very rarely happens that one man combines the qualities of a first-rate draftsman, photographer, plate maker and printer.

Collective or industrial production may be effected by various methods. A printer owning a small but well-equipped printing works may turn his plant into a complete counterfeiter's workshop while, for the sake of appearances, he continues to do some honest work as well. The counterfeits he produces may be very deceptive, as they are made by skilled workers. This method of production under the cloak of a regular business is very rare. Alternatively, a number of persons attracted by prospective profits may plan to make counterfeit currency and, to this end, acquire a likely place equipped as a workshop, the necessary plant and some skilled artisans. They constitute a clandestine organization, comparable to a regular commercial company in which they become the partners. After the notes have been printed, the counterfeiters are faced with the difficult problem of making arrangements for the passing on of their products. Since distribution of small lots to several persons will often require lengthy and tedious negotiations, they prefer another, more hazardous method of solving this problem. Two or three members of the gang visit first-class jewelers, furriers or other dealers in valuable articles that can be easily resold. They buy some precious stones, for instance, and pay for them in genuine currency. Next day they return and purchase a much larger quantity of high-priced articles, this time paying in counterfeit notes. When the jeweler detects the real nature of these and reports his discovery to the police, the criminals have already left the country. Merchants are often duped by this trick and the counterfeiters who use it are generally members of an international gang. Another instance of industrial counterfeiting is the use by the governments of certain countries of counterfeit currency as a means to attain their political purposes or to cause economic ruin to states at war with them; e.g., Reinhard Heydrich's notorious wholesale production of counterfeit Bank of England notes during World War II. For the prevention of this crime it is essential that paper currency as well as coin meet the highest

possible standard of quality to provide a deterrent to counterfeiters.

(J. W. K.)

## UNITED STATES

The constitution of the United States expressly provides in art. I, sec. 8, par. 6 that "The Congress shall have Power . . . To provide for the Punishment of counterfeiting the Securities and current Coin of the United States." The federal agency charged with the suppression of counterfeiting in the United States is the United States secret service, which was established July 5, 1865, as a division of the treasury department (*see* SECRET SERVICE, U.S.).

Records of amounts of counterfeit money seized during those early years are not available, but for the year ended June 30, 1876, the representative value of counterfeit coins and bills captured by the secret service approximated \$232,000. At that time the government and the people themselves were handicapped in the suppression of counterfeiting because of the great number of national banks on which notes were issued and the variations in the engraved designs. New notes placed in circulation were quickly counterfeited before the public became acquainted with the appearance of the genuine notes. When counterfeit notes drawn on one national bank began to be widely detected, the counterfeiters would circulate new issues under the name of some other bank.

**Crime Prevention Through Education.**—During the four peak fiscal years, 1933 to 1936 inclusive, victims of passers of counterfeit notes in the United States lost an average of \$771,000 yearly. Although banks were all warned to be on the alert for certain dangerous counterfeit bills, there was no concerted effort to warn retail merchants or others about such counterfeits, and the general policy of the secret service with regard to counterfeiting was one of secrecy since it was feared that alarms about extensive circulation of counterfeits would tend to shake the faith of some of the people in the currency of their country.

When the secretary of the treasury, Henry Morgenthau, Jr., appointed Frank J. Wilson chief of the secret service in 1937, the secretary requested that strenuous efforts be made to reduce to a minimum the losses suffered by victims of counterfeiters. As a departure from the age-old methods of investigation, prosecution and imprisonment, Chief Wilson decided to fight the crime of counterfeiting by teaching the public how to detect bogus money. In a trial of this idea, the secret service printed and distributed to banks and retail stores hundreds of thousands of warning circulars bearing descriptions of counterfeit bills currently in circulation. These warning notices bore diagrams showing the denomination and type of the counterfeit described, the particular defects to aid in checking a suspected bill and directed attention to the "check letter" and "face plate number" appearing in the lower right corner of the face of the bill.

For the fiscal year 1937 losses suffered by victims of counterfeiters were reduced to \$519,366, and it was evident that the dissemination of the secret service descriptive warnings had had some good effect. Chief Wilson decided to pursue his idea further and early in 1938 sent a picked group of secret service agents to New York city, where they made a door-to-door canvass of approximately 100,000 retail stores and taught merchants and employees how to tell the difference between good and bad money. For the fiscal year 1938 losses to victims of counterfeiters fell to \$407,320.

In 1938-39 secret service agents began a series of instructive lectures to retailers, bankers and others in all parts of the country. For the fiscal year ended June 30, 1939, counterfeiting losses had dropped to \$294,057, and the secret service decided to intensify its efforts. Late in 1939 the secret service began a campaign against the counterfeiter under the slogan "Know Your Money." Secret service agents produced a sound motion picture entitled *Know Your Money*, which graphically portrayed methods of detecting counterfeit bills and coins and the *modus operandi* of passers of counterfeit bills. The federal laws prohibit the photographing of United States money in whole or in part, but Secretary Morgenthau granted special permission to the secret service to film genuine and counterfeit bills and portions thereof for this educational campaign.

To supplement the motion picture, the secret service produced millions of copies of a four-page leaflet telling how to detect counterfeit money, and arranged to give one leaflet to every person who saw the picture and to distribute copies to banks and business houses for their information and protection. More millions of the pamphlets were reprinted by banks and stores for distribution to their customers.

In Sept. 1940 the secret service produced a 32-page *Know Your Money* booklet, illustrated with pictures of counterfeit bills and telling in detail how to detect bogus notes and coins. Having in mind as its first objective removal of temptation from the youth of the country to engage in criminal careers, the service inaugurated efforts to have this booklet adopted by high schools in all parts of the country as a part of their regular curriculums. This was a productive effort and soon many schools were instructing their students in the detection of counterfeit money.

With the crime prevention program in full swing, the victims of counterfeit note passers lost only \$48,000 during the fiscal year ended June 30, 1942—an impressive drop of 93% compared with the 1933-36 yearly average. Fifteen years later, during the fiscal year ended June 30, 1957, U.S. secret service agents captured \$1,548,167 in counterfeit bills. Of that total, however, more than \$100,000 was successfully passed on storekeepers and cashiers; the balance was seized before it could be put into circulation.

**How to Detect Counterfeit Bills.**—Years of experience have proved to the secret service that the best detector of counterfeit money is the properly trained human eye. The person who is best able to see the difference between the bogus bill and one that is genuine must know just what a genuine bill looks like. The only way such knowledge can be gained is through a careful examination of all parts of a genuine bill, and it is such a study that is advocated by the secret service to help Americans defend themselves against the counterfeiter.

The portion most difficult of good reproduction is the portrait on the face of every note. The portraits of famous Americans on United States paper money identify the denominations of the bills on which they appear, as follows:

\$1 .....	Washington
\$2 .....	Jefferson
\$5 .....	Lincoln
\$10 .....	Hamilton
\$20 .....	Jackson
\$50 .....	Grant
\$100 .....	Franklin
\$500 .....	McKinley
\$1,000 .....	Cleveland
\$5,000 .....	Madison
\$10,000 .....	Chase

The genuine portraits are lifelike and distinct, and the shading which characterizes the facial features consists of numerous delicately executed dots and dashes. The oval background surrounding each portrait comprises a series of tiny squares, formed by the crossing of very fine vertical and horizontal lines. On most counterfeits the portraits are defective in the shading in the face, and many of the little squares in the background are filled with ink or are flecked with white where the vertical and horizontal lines are broken. In the genuine portrait the eyes are always clear and expressive, but in most counterfeits they are dull, distorted or otherwise executed so that they do not compare favourably with the genuine.

These differences alone between the genuine and counterfeit portraits prompt the secret service advice to the individual to compare any questionable bill with another of the same type known to be genuine. Such a comparison will make evident any differences between the two to such an extent that if one is a counterfeit it can be classified as such.

Only three types of currency are in circulation in the United States—(1) silver certificates; (2) United States notes; and (3) federal reserve notes. Part of the design of every genuine bill includes the treasury seal, a small circle edged with sharp points like the teeth of a saw, enclosing an angle square under which is a key and over which is a balance scale, all mounted upon a dotted

white shield within the circle. Surrounding the design are the Latin words *Thesaur. Amer. Septent. Sigil.*, representing the "Seal of the Treasury of North America." On silver certificates the seal and the serial numbers are printed in blue; on United States notes they are in red, and on federal reserve notes, in green. Thus, the type of any bill may be quickly determined merely by the colour of the treasury seal and the serial numbers. In addition, the words "Silver Certificate," "United States Note" or "Federal Reserve Note," as the case may be, are engraved at the top centre of the face of a bill.

On many counterfeits the sharp points around the outer edge of the treasury seal are blunt or broken. Here again, a comparison of the seal on a questionable bill with the seal on a genuine bill will show the difference.

The serial numbers on genuine United States paper money are printed in a distinctive type style, and numbering blocks of the kind used for this purpose cannot be obtained except by the bureau of engraving and printing. Therefore, in producing a counterfeit, the counterfeiter must either use numbers unlike the genuine, or must try to copy the genuine numerals. In the first instance a comparison will show the difference in the style, and in the second instance the copies or imitated numbers are usually poorly spaced or crookedly aligned, so that a comparison will indicate they are not authentic.

The border design of every genuine bill includes an intricate lacelike network of fine white lines. The patterns for these lines are produced by a machine known as a geometric lathe, and the lines are technically called geometric lathework. In a genuine bill these lines are clear and unbroken, but on most bogus notes the border is too dark because many of the spaces between the lines are filled with black ink caused by inferior etching, or perhaps too light because the white lines are thicker than the genuine, creating a bleached appearance.

It is believed by some that rubbing a bill on a piece of paper will prove whether it is genuine or counterfeit, through removal of the colour. This is definitely a fallacy because the ink can be rubbed from a good bill as well as a bad one.

**How to Detect Counterfeit Coins.**—The manufacture of spurious coins does not involve losses as great as those suffered by victims of counterfeit bills. This is due, of course, to the fact that there is a wide margin of difference between the value of metal money and the representative value of paper money.

The passer of counterfeit coins depends upon the carelessness of his victims in the same way as does the passer of counterfeit bills. Genuine silver coins have a corrugated outer edge, known as the reeding. Consisting of evenly spaced ridges, this feature was included on silver coins originally to prevent unscrupulous persons from cutting or filing from the edges of the coins small bits of silver, which they would then sell for the intrinsic value of the metal so derived. Later, however, the reeded edges of silver coins formed considerable protection against counterfeiting since the corrugations on most bogus coins are only partially executed, unevenly spaced or entirely missing in places. Thus, a comparison of a questionable coin with one known to be genuine, or even a careful scrutiny of the ridges around a questionable coin, will usually indicate whether it is good or bad.

Most counterfeit coins are made of metal alloy which does not ring as clearly as genuine coins when dropped on a hard surface and which is usually much softer than silver. Therefore, questionable coins should be dropped on a hard surface to test their ring and should be cut with a knife to test their quality. If a coin sounds dull or is easily cut, it is undoubtedly a counterfeit.

It is also a fact that most counterfeit coins feel greasy, so it is wise to feel all coins, and if one feels slippery or greasy it should be further examined for defects in the reeding or other characteristics.

Bogus silver coins may be detected with a mixture of ingredients in a liquid solution, the formula for which is as follows:

Nitrate of silver .....	10 grains
Nitric acid .....	1 c.c.
Distilled water .....	30 c.c.

This "silver test" may be obtained for a few cents in any drug store. A drop applied to a counterfeit coin which does not have a high silver content will turn black. The solution will not discolour a genuine silver coin and will not react on a counterfeit coin which is made of silver or which contains a great deal of silver, but since most counterfeits are made of base metal the acid will detect them. It cannot be used to detect counterfeit nickels or gold coins.

If you receive counterfeit money the secret service recommends the following actions:

1. Do not return it.
2. Notify police at once.
3. Try to delay the passer under some natural excuse.
4. Avoid argument. If necessary, say the police will handle the matter.
5. If the passer leaves, write down his description.
6. Write down the licence number of any automobile used by the passer or his accomplices.

**Stamps.**—Secret service agents have arrested makers and users of counterfeit United States internal revenue tax stamps which are usually affixed to bottles of taxable alcoholic beverages in an effort to evade the required tax payments. Such stamps are issued by the government and are protected by the laws which provide for the suppression of counterfeit money.

The secret service, in co-operation with post office inspectors, has also captured plants for the manufacture of counterfeit United States savings stamps and postage stamps, but this type of counterfeiting is somewhat unusual and has never been very extensive.

**Confiscation of Counterfeits.**—The federal laws for the protection of obligations of the United States provide that anyone having custody or control of any counterfeits of such obligations who shall fail or refuse to surrender them to an authorized agent of the treasury department shall be fined not more than \$100 or imprisoned not more than one year, or both. All banking institutions are authorized agents of the treasury department within the meaning of this statute and, as such, are legally authorized to confiscate counterfeit money from their customers or other persons who present it.

**Penalties For Counterfeiting.**—Counterfeiting is a felony. The laws of the United States provide that any person who has knowledge of the commission of a felony recognized by the federal courts, and who does not at once make such knowledge known to the authorities, shall be fined not more than \$500 or imprisoned not more than three years, or both. Therefore, one who has any knowledge of counterfeiting activities should, for his own protection, promptly report such knowledge to the secret service. (Sec. 286, title 18, U.S. code.) (F. J. W.)

## GREAT BRITAIN

In Britain, as in every sovereign state, the making of money is the prerogative of the government. The crown alone can endow money with the authority that will make it acceptable for the purposes of trade and commerce. There have been several coinage acts, of which the principal, as far as counterfeiting is concerned, is the Coinage Offences act of 1861, whose main effect is to make counterfeiting of coin a felony. Counterfeiting includes the colouring or gilding of a low-value coin so as to make it resemble a gold or silver one as well as the impairing or lightening of a coin. Since 1861 there have been several supplementary coinage acts, and provisions have been made for fixing the metallic content of coins and the amounts of different coins which may be offered as legal tender. The international convention of 1929 for the suppression of counterfeiting (see below) was implemented in Britain by the Counterfeit Currency (Convention) act of 1935. This sought to apply to foreign currency the provisions relating to British coin and imposed penalties for importing and exporting counterfeit foreign coin.

Gold coin was withdrawn from circulation at the outbreak of World War I in 1914; and for all practical purposes the money in circulation in Great Britain has since consisted of token coins and currency notes. The Currency and Bank Notes act, 1914, empowered the treasury to issue £1 and 10s. notes which were to be

legal tender for any amount and to be current in the same manner and to the same extent as the gold sovereign and half-sovereign. From 1914 onward, consequently, there were two note issues in circulation, those of the Bank of England, i.e., bank notes proper, and those of the government, or treasury notes. The two were amalgamated by the Currency and Bank Notes act, 1928, which provided that currency notes were to be deemed bank notes and transferred the whole of the note issue to the Bank of England. By this statute, too, currency notes were to be deemed bank notes in such special connections as forgery.

The risk of forgery has always been a source of anxiety to those persons legally authorized to issue paper money. As far back as 1697 an act was passed by which forgery or alteration of a bank note was deemed a felony. At common law, forgery was a misdemeanour; but most forgeries were made felonies by statute and forgery of notes was a capital felony until 1832. The number of persons executed for it has varied. It is said that in 1817 three hundred persons were hanged as forgers; but in the three years prior to 1832 only 15 suffered execution.

In the early days of the Bank of England, notes were written by hand and could be altered. It is a measure of the informality of the 18th century that in 1722 the Bank of England sent an official to interview a man found guilty of erasing and altering a bank note and, before the latter was executed, obtained his advice on how to counteract the practice. The essence of the problem of forgery is contained in the old maxim that what one man can make, another can copy. Hence there has been a never-ending struggle against forgers and, apart from the legal sanctions available to the state, the only security measures have been the quality and nature of the special bank-note paper, always restricted to this use, and its design and manufacture by one trusted firm. Provided the genuineness of the currency is safeguarded with the utmost vigilance, it is doubtful if an attempt at wholesale forgery to secure the economic breakdown of a nation, such as Reinhard Heydrich's in 1941, can ever succeed. It is known that many millions of pounds' worth of notes in denominations of £5, £10, £20, £50 and even higher values were forged in the German experiment of World War II; but before mass release of these notes could be arranged the project was abandoned.

Perhaps the most interesting case of forgery and counterfeiting in England came to light during the 1920s. This was the famous Portuguese bank note case. In 1924 Waterlow and Sons, a famous and honourable firm of printers, were deceived into printing an ostensible order of bank notes for the Bank of Portugal. Many thousands of spurious notes were thus printed on genuine plates, smuggled out of England and used as capital for a small Portuguese bank, through which they were distributed. Toward the end of 1925 the unduly large number of 500 escudo notes in circulation aroused the suspicions of the Bank of Portugal. Investigations revealed the plot. Then followed the task of separating genuine notes from false. This was difficult, for both were printed on genuine plates. The whole of the issue was withdrawn for study and minute differences discerned in the printing enabled the authorities to distinguish the forged notes. Their total value was equal to £3,000,000, and about one-third of them had passed into circulation. In an action brought by the Bank of Portugal against the printers, damages of £610,392 were awarded against the firm in 1932 by the house of lords.

The English law of forgery depends principally on the Forgery act, 1913, as amended by the Counterfeit Currency act, 1935. The 1913 act defines forgery as the making of a false document to be used as genuine and the counterfeiting of seals and dies. The act deals not only with definitions and penalties but includes also provisions regarding the possession of paper or implements for the forging of bank notes. Accessories and abettors clearly are liable; but it is an indication of the gravity of the offense that the act treats them as principals.

Special provisions are also made for the issue of search warrants. (GA. S.)

## INTERNATIONAL POLICE ORGANIZATION

The chaotic conditions in Europe after World War I caused

crime to increase beyond all bounds and led police officials in many countries to create an international police organization. In 1923, when the imperative necessity of checking this wave of crime became evident, the appeal made by J. Schober, superintendent general of the Vienna police, inviting every government to co-operate met with a favourable response. Many countries were represented at the International Congress of Police Officers held in Vienna in Sept. 1923. The fact that counterfeiters were ranking high in the postwar world of international criminals was explained by H. von Liebermann, chief of the criminal police, Berlin, who pointed out that no other crime had such a marked international character. The depreciation of Poland's monetary unit in 1921 was largely due to the wholesale counterfeiting of Polish 1,000-mark notes, with which the central European markets were openly deluged. The wave of counterfeit German bank notes with which Europe was inundated immediately after World War I continued to imperil the parity of the German bank notes as late as 1920. When Hungarian bank notes of a certain denomination had to be exchanged after their withdrawal, an extraordinarily high percentage of them proved to be counterfeits. In 1921 strenuous efforts had to be made in the Netherlands to suppress the counterfeiting of notes of 25, 60, 100, 200 and 300 florins. Czechoslovakia, Italy, Rumania, Belgium, Denmark and Great Britain also had to cope with the counterfeiting of their national currencies. In Great Britain a large percentage of counterfeit Bank of England notes, particularly the £1, £10 and £20 notes, proved so deceptive that even observant and experienced money handlers were unable to identify them.

Counterfeiting committed in any one country may affect other countries as well; e.g., counterfeit U.S. bank notes made in Germany will—even in the event of their being circulated in Germany only—soon pass the frontier of a neighbour country. Speculation in foreign currency creates a great demand for it, with the result that the centres of this speculative trade are likely to become centres of the traffic in counterfeit currency as well. When the market value of the currency of a particular country becomes so low that counterfeiting is unprofitable, counterfeiters can turn to the production of money of a higher parity.

To achieve international co-operation in suppressing this crime, central offices dealing with cases of counterfeiting were in existence in several countries, including the Netherlands, Poland, Czechoslovakia, Germany and Austria and a resolution purporting to constitute an International Criminal Police organization (Interpol) was unanimously adopted. Vienna was designated as the headquarters of the organization in 1923 when it was set up, but this was transferred to Paris in 1946. Its constitution afforded a form of co-operation between police authorities on an international level. The Interpol authorities entrust the repression of counterfeiting to specialized officers, versed in the technicalities of production; they furthermore affirm that the collection of all relevant information should be centralized in every country and that the secretariat general of the International Criminal Police organization, officially designated as International Central bureau, should be regularly notified of every case of counterfeiting and its technical particulars.

At the 40th session of the council of the League of Nations, held on June 10, 1926, Aristide Briand, the French minister of foreign affairs, proposed that counterfeiting be dealt with as an international crime and suggested that the several governments amend their penal codes to provide that the counterfeiting of foreign currency be liable to the same measure of punishment as the fraudulent imitation of their national money. He furthermore recommended the creation of an international bureau to be charged with the collection of all information on counterfeiting and said that it would be advisable to entrust to a committee, selected from competent persons to be appointed by the various governments, the work of framing a draft convention for the suppression of this crime.

A diplomatic conference was held in Geneva on April 9, 1929, and was attended by delegations from 35 governments and by a delegation of the International Criminal Police commission in an advisory capacity. It drew up a convention with a protocol and

final act and was concluded on April 20, 1929. It was signed (until closed on Dec. 31, 1929) by the governments of Albania, the United States of America, Austria, Belgium, the United Kingdom, India, Bulgaria, China, Colombia, Cuba, Czechoslovakia, free city of Danzig, Denmark, France, Germany, Greece, Hungary, Panama, Poland, Portugal, Rumania, Spain, Union of Soviet Socialist Republics, Switzerland and Yugoslavia.

The object of the convention was to render more effective the prevention and punishment of counterfeiting currency. To this end the convention provided rules for unifying, to a certain extent, the penal laws of the signatory powers and for the centralization and co-operation of police action in the various countries. Previously in many countries the counterfeiting of foreign currency was punished much less severely than the counterfeiting of national money and in several, the counterfeiting of foreign money was not an indictable offense at all. Again in the various countries, not excepting those where the crime of counterfeiting was liable to most severe retaliation, a differentiation was made between the various phases of the crime, so that the punishments imposed for merely passing counterfeit money, for participation in counterfeiting and for the possession of instruments for counterfeiting, greatly differed. Furthermore, the rules governing extradition were such that it was usually most difficult, and often impossible, to institute criminal proceedings against counterfeiters who had escaped from the country. The convention sought to improve on this state of affairs and in all participating countries legislation had to be such that currency counterfeiters were prosecuted and punished without exception and could nowhere go free with impunity.

The second aim of the convention was to organize international co-operation between the police authorities of the respective countries. To this end it stipulated that in each country a central police office should be established in which all information and investigations relating to the counterfeiting of currency should be centralized, and that provision be made for an international office to act as clearinghouse between the national central offices.

Thirty-two powers, including the Soviet Union, ratified the convention of Geneva. Even those states which did not would be influenced in determining the measure of punishment for counterfeiting by the judicial practice of the other states; their legislation, in accordance with the traditions of international law, would be gradually adapted to the provisions of this convention. Such colonies, possessions and protectorates as acquired independence usually recognized the international obligations of the metropolitan powers to which they formerly belonged and thus adapted their common law to the provisions of the convention. (J. W. K.)

**COUNTERFORT**, a form of buttress (*q.v.*) used for the strengthening of walls, originally of medieval fortifications, but later of other walls (e.g., cofferdams). With the introduction of cannon as siege weapons in the 15th century, ordinary masonry walls backed with earth were not sufficiently strong. They were, therefore, strengthened with buttresses or counterforts from the inside of the wall. Later the counterfort often took the form of an arched gallery, built behind the wall under the rampart.

**COUNTERPOINT.** The word counterpoint has three meanings in music: (1) it may mean a melody accompanying an existing melody; (2) it may embrace the whole art of combining melodies; (3) it may describe a limited number of styles grouped together for purposes of study or examination. This article surveys the history of counterpoint in western European music in the second of the above senses. It must be borne in mind that it is impossible to separate the constituent parts of musical speech into compartments of their own, and therefore many details of contrapuntal technique, insofar as they are harmonic, are discussed in the article **HARMONY**.

**Contrapuntal Forms and Styles.**—Strictly speaking the addition of any extra part to an existing part produces counterpoint. There is, however, a distinction between counterpoint that is constantly parallel (similar motion) and that which may also include

contrary and oblique motion. If two parts always move in similar motion, the ear regards them essentially as one part enriched by doubling, but if their melodic direction diverges they take on separate identities. Further, counterpoint whose constituent parts move together in similar rhythm is likewise limited rhythmically. Styles dominated by parallel motion and/or by similar rhythms are said to be homophonic and are contrapuntal only insofar as they may be restricted to a particular number of vocal or instrumental melodic lines. Styles whose different voices are more independent in direction and rhythm are said to be polyphonic and more truly contrapuntal. Independence in this context is a comparative term, because the addition of one note to another also produces harmony; and however independent in direction and rhythm individual voices may be, their combination as harmony is a vital consideration; their melodic and rhythmic shapes are bound by this consideration.

Contrapuntal forms are those that are built on a combination of independent voices or parts, e.g., canon (*q.v.*), in which one voice imitates more or less exactly the melody of another voice.

The earliest known music in more than one part is parallel organum and free organum. The former is homophonic doubling at certain intervals of the original melody while the latter is a little more polyphonic in outlook, the added melody (*vox organalis*) starting and ending with the chant (*vox principalis*) but diverging from it otherwise, though mostly in parallel motion. The two important developments in the age of organum were: (1) the use of contrary motion with the crossing of parts (*c.* 1100) and (2) the use of more than one note in *vox organalis* to one note in *vox principalis*. The latter paved the way for the introduction of a more florid metrical system. As the added part became more complex, the term *discantus* was introduced.

The school of Notre Dame in Paris developed the use of rhythmic modes in polyphonic writing. The organa of this school use the modes partially, containing sections or voices in freer rhythms, while *discantus* consisted completely of parts measured by modal rhythms. In the *discantus*, Pérotin used *clausulae*, which are repeated rhythmic and melodic patterns (derived from the plain chant), in the tenor. The melodic patterns did not necessarily coincide with the rhythmic patterns. Pérotin wrote organa for two, three and four voices. Naturally the individual melodies of organa for three and four voices are more constricted than in two-part writing, the upper parts, slightly decorated, moving in octaves or fifths with the tenor. An interesting feature of Pérotin's work is his use of imitation with (1) an early type of double counterpoint, usually repeated with the voices interchanged; and (2) the use of actual canon.

Example 1 (two of the voices are omitted) shows not only a grasp of the use of contrary motion but also a contrapuntal use of rhythm. The rhythm of the whole is made up of the alternating rhythms of each part.

A second style used by the school of Notre Dame for metrical texts was *conductus* (*q.v.*). This was characterized by all parts moving in almost similar rhythms and was thus a more homophonic style than organum.

Voices in the 13th-century motet sang different texts simultaneously and the technique included the interchange of voices and the use of tenor patterns, both borrowed from organum. In the early 13th century the upper voices were much in the *conductus* style but about 1250 a new style developed, called *Franconian* after Franco of Cologne. In this, triplum, the highest voice in the motet, became more ornate and important and, though constantly crossing with duplum, almost took the character of a tune, the other voices accompanying. The interchange of voices, canon and

the *quodlibet* technique of combining existing melodies simultaneously were used. Another partially contrapuntal device used was the *hocket*, which is characterized by rests between notes in individual parts, the notes of one part filling in the rests in the other. (The top part in Ex. 2 is a typical *hocket* part in bars 5-7 of the extract.) One of the most important features of good contrapuntal writing of all periods is the completion of a rhythmic pattern by the concerted effect of the rhythms of different parts (as in Ex. 1), and the *hocket* is an early realization of this.

The secular style was represented, apart from secular motets, by the so-called *cantilena*, which included polyphonic *rondeau*, *virelai* and *ballade*; these borrowed melodies from secular monodies and used a *conductus*-like technique.

The 14th century saw the rise of true counterpoint. In the isorhythmic motets of Philippe de Vitry and Guillaume de Machaut, in the madrigals of Jacopo da Bologna and in the *caccia*, the different voices have much more melodic life and direction. They use isorhythm, a formal device consisting of an extended rhythmic pattern repeated throughout the work in different melodic forms. Isorhythm has a formal function, and Machaut introduced it not only into the structurally important tenor parts but also into the other voices, which thus achieved more independence. An increasing give-and-take characterized the upper parts, and the Italian *trecento* composers favoured newly composed tenor parts, often more quick-moving in keeping with the other parts. The emancipation of the tenor gradually led to its becoming a contrapuntal equal of the other voices. Such a passage as Ex. 2 has no parallel in earlier music.

The canonic form taken by the *caccia* is inherently contrapuntal.

Apart from the equality of voices, the greatest spur to real contrapuntal writing was the introduction of imperfect concords as regular harmony notes. This apparently originated in England, where there is at least one motet of the early 14th century (*Ave miles coelestis—Ave rex patrone—Ave Rex*), in which the parts, though rhythmically very much in *conductus* style, are melodically remarkably independent, with a distinct sense of line. Such use of imperfect concords enabled John Dunstable to evolve a systemic treatment of dissonance that dominated the harmonic system in use from about 1500 to the 20th century.

Though *cantus firmus* (*q.v.*) methods were used to the end of the 16th century, and indeed to the present day, their use was increasingly different in that the *cantus firmus* was no longer confined to one part. The methods of using the *cantus firmus* included: (1) canons based on the *cantus firmus*; (2) highly decorated melodies following the main outlines of the *cantus firmus*; and (3) the more ancient use with, however, much more equality in other parts, including imitation.

The Flemish school of Jean d'Okeghem, Jakob Obrecht and (a little later) Josquin Després developed these trends further, particularly in their church music. In replacing a normal three-part texture with one of four parts, they encouraged the use of the four registers of male voices (treble, alto, tenor, bass). Thematic equality demanded single texts, though there are examples of old-style multitextual motets, even in Després.

Single texts also encouraged other means of extension, such as the use of canon, and the sectional treatments, so usual in 16th-century vocal music, which was often a combination of polyphonic and more homophonic styles. Canon and fugue, the latter an extension of the former (*see FUGUE*), are logically the most natural of contrapuntal methods. Any distinctive melody repeated at a fairly close and therefore recognizable distance in another part will result in some contrary motion, some rhythmic alternation and

go ne.

some dissonance, and the entries of different voices will produce movement.

**Multiple Counterpoint.**—From the problem of providing a second part as countermelody and from that of providing the second entry of a fugal subject arose the idea of double counterpoint, a device much used in the late 16th century, especially by William Byrd. In the following example themes (a) and (b) are interchangeable in voice position, so that whatever voice sings

(a), another voice may sing (b).

Apart from the obvious musical advantages in such a procedure there is the added possibility of using two distinctive themes in double counterpoint, each fitting its own phrase of the text. Such a technique was often used in vocal fugues by Handel and Bach. Double counterpoint is, of course, constantly used in instrumental fugues that have regular countersubjects.

The technical problem involved in multiple counterpoint lies

in the alteration of intervals between parts so inverted. Ex. 3 shows double counterpoint in the octave. Intervals inverted in the octave behave as follows: seconds become sevenths, thirds become sixths, fourths become fifths, octaves become unisons. Such inversions become reciprocal. This process can be expressed arithmetically, by subtracting each interval from nine, the result being the inverted interval. Therefore, in such counterpoint discords invert to discords and concords to concords, with the single exception of the concordant fifth, which inverts to become the dissonant fourth. Hence fifths must be treated in some such manner as in Ex. 4, so that in inversion the dissonance is resolved.

The problems of inverting in other intervals can be deduced arithmetically: inversion in the tenth, for example, by subtraction from eleven, in the sixth by subtraction from seven and so on. The advantage of inversion at intervals other than the octave is the harmonic variety that can be so obtained. Some examples of invertible counterpoint are shown in Ex. 5.

Note that the alteration in the form of shortened note values in the inner part in (b) is a matter of keyboard convenience and that the rhythmic device in (c) is a purely artistic consideration. Exact inversion is possible in this instance, though generally inversions of triple counterpoint are often altered in details. The

extract below (Ex. 6) shows an example of triple counterpoint at the 12th and incidentally at the ninth.

Ex. 6 is a tour de force as triple counterpoint, which is normally not possible in any interval but the octave because the changes of harmony involved in inversion at other intervals are too complex, and because such counterpoint would always involve incidental relationships. At the octave, triple counterpoint is quite common generally, and Bach found it particularly useful as a means of both linking and varying different episodes in fugues (as in Ex. 5). Quadruple counterpoint occurs quite often in Bach; even quintuple appears in his *Magnificat*. In the quintuple counterpoint of *Fecit Potentiam* in the *Magnificat*, a new free part is given to the vocal tenor that is actually invertible (over the given bass), though not so used by Bach. An independent bass does not so much remove the difficulty of inverting extended coherent passages of multiple counterpoint (i.e., any more than quadruple) as it removes some of its pointlessness. First, the human ear is incapable of hearing many lines of counterpoint accurately; secondly, the very length of a movement required to use different permutations of extended multiple counterpoint makes its use pointless; thirdly, the harmonic constriction (which is less in very chromatic passages) that denies the normal use of the fifth would encourage dullness and thinness. In the finale of Mozart's "Jupiter" Symphony, K.551, the quintuple counterpoint occupies just less than two bars of *molto allegro*,  $\frac{3}{8}$ ; however wonderful that finale may be artistically, the almost miraculous contrapuntal powers ascribed to Mozart on the strength of it are overrated,

Ex. 5

Ex. 6

Free Bass

especially in view of the fact that the themes concerned are such commonplace contrapuntal tags. But there can be few more perfect examples of contrapuntal writing than the fugal exposition occurring in bars 36–52 and the various strettis that occur later in the movement. Sextuple counterpoint occurs in Bach's Concerto in C for three harpsichords and in his cantata movement *Nun ist das Heil*.

**Other Kinds of Inversion.**—The word inversion is used also in an entirely different sense to mean the turning upside-down of melody. Total inversion of passages in several parts is described as "mirror" counterpoint, exemplified by Contrapunctus XII and XIII in Bach's *Die Kunst der Fuge*. Such a technique and that of crabwise movement (retrograde melody called *cancrizans*) have rarely been used with great artistic success.

It will be noted that this article ceased to be historical from the point at which multiple counterpoint was discussed. From the 16th century onward, counterpoint, as distinct from contrapuntal forms and devices, cannot be separated from harmony. The details of harmony are contrapuntal and are discussed in the article **HARMONY**. Musical style has been more or less contrapuntal according to circumstances and further information will be found in the articles **CANON**, **FUGUE**, **MADRIGAL**, **MOTET**, etc. The 20th century has seen a renewed interest in contrapuntal forms. But contrapuntal methods have varied with harmonic methods and it would be impossible to discuss details of style within the confines of this article.

**Strict Counterpoint.**—This is an entirely academic type of study that originated after the great polyphonic age of the late Renaissance but purports to embody the stylistic principles of that period. Its methods of using *canti firmi*, to which were added counterpoints, were to some extent founded on 16th-century methods, as Thomas Morley's book shows, though most of its rules bore little relation to the practice of that age. It is still widely used in contrapuntal studies. "Free counterpoint" is a name given to an academic study that is so vague in its stylistic principles as to be reducible to the whim of each particular teacher or textbook author. The term is also used, properly, to describe nonrecurring counter melodies in fugue and other forms.

**COUNTERPOISE**, in radio engineering, an artificial ground for an antenna, consisting of a network of wires elevated above and insulated from the earth. It is used in places where it is difficult to obtain a good ground (e.g., where there is extremely rocky soil). A combination of counterpoise and buried-wire grounds is also possible.

See **ANTENNA (AERIAL)**.

**COUNTERVAILING DUTIES**, customs or excise duties (taxes) the object of which is to neutralize unwanted and unintended effects of other duties. They may be imposed for the protection of domestic producers against foreign rivals not subject to excise duties, and also for the protection of foreign producers against domestic rivals whose goods are not subject to customs duties, or for the protection of one set of domestic producers against another set. When customs or excise duties are adopted or increased solely for revenue-raising purposes and not for the encouragement or discouragement of the production or import of certain goods, the government imposes countervailing duties to prevent any unwanted consequences outside the fiscal sphere.

The principle became firmly established in Great Britain during the 19th century as a result of the endeavour to reconcile free trade with the need for providing revenue by means of customs duties. Such duties were adopted regularly even by Liberal governments on the assumption that, so long as countervailing excise duties were adopted at the same time, the customs tariff did not protect domestic producers and was therefore not incompatible with the basic principle of free trade. Prior to World War I

this practice was a general rule. For each fiscal customs duty there was a countervailing excise duty, even on the negligible British tobacco production. For a long time British wines escaped countervailing duties, but as a result of the increase in their production a nominal duty of 1s. per gallon was imposed in 1927, which was gradually increased almost to the level of the preferential duty on Commonwealth wines.

It was the usual practice to fix customs duties slightly above the countervailing excise duties in order to compensate home producers for the inconvenience caused by the imposition of the excise duties. For instance, there was originally a difference of 2d. per proof gallon of spirits under the trade agreement of 1860 with France. This difference was subject to changes and was raised to 2s. 10d. after World War I.

When excise duties were adopted for fiscal purposes, countervailing customs duties were applied in order to protect domestic producers against their foreign competitors. Countervailing duties were also adopted in some instances to protect one domestic industry against another when products not subject to excise duty could easily be substituted for those that were taxed. For instance, in 1928 a countervailing duty was imposed in Britain on mechanical lighters to offset the duty on matches and since 1930 petrol (gasoline) substitutes have been made subject to countervailing duties which are adjusted to accord with changes in petrol duties. The term countervailing duties is sometimes interpreted as applying to customs duties imposed for the prevention of unfair competition by foreign rivals enjoying the advantages of a strongly organized industry, unduly cheap exchange rates, sweated labour or subsidies. Thus countervailing duties were levied in Canada in 1904 on steel rails produced in the United States on the grounds that these rails were sold at prices below those charged in the home market. But such duties are now better known under the term of antidumping duties and are frequently resorted to in many countries. (P. Eg.)

**COUNTRY DANCE.** This type of social dance, regarded as deriving from the carole (*q.v.*), is for a number of couples, though there is historical evidence of performance by women only as a skill *sui generis*. The term was narrowly applied to a social dance practised by gentlefolk from the mid-16th century onward; similar dances, usually referred to as "traditional," are known to have existed contemporaneously among countrypeople.

The origin and precise meaning of the term "country dance" is obscure and disputed. There is no positive evidence of rusticity and the sources of knowledge concerning structure, movements and music are of urban, even courtly, origin: Italian (15th–16th centuries), English (16th–19th centuries) and French (18th century). The Italian *contra-passo* may perhaps be accepted, but not the French *contredanse* (a 17th-century gallic rendering; cf. "ros-bif"), as the source of the English word already in use about 1560.

The country dance exists in three main forms: (1) circular for an indefinite number, such as the English 15th-century "round" or hornpipe (*q.v.*); (2) "longways" or double-file for an indefinite number, either processional or in a "set"; (3) geometrical formations or "sets" usually for two, three or four couples. Insofar as the country dance can be regarded as rustic or "folk," forms (1) and (2) are found in that context; the few rustic examples of (3) are generally considered to be derivations of the quadrille and the "set-running" of eastern U.S. and Canada to be a compound of doubtful origin exhibiting characteristics of carole and quadrille. Both (2) and (3) were known in Italy in the 15th and 16th centuries, in England from the 16th century onward and as a supposed English invention, (2) was re-exported to Europe as *contredanse* (*q.v.*) and *Kontratanz*, enjoying a prolonged vogue. Apart from the processional (e.g., the well-known Helston Furry), carrying the participants over an extended route and its modification "square dancing," which disposes the double-file in an endless circle, the country dance "set" remains in the same place. "Figures" in great variety are executed between couples or individuals opposite or adjacent to one another, while in "progressive longways" continuous interchange brings a new leading couple to the head of the set with every repetition.

In England the chief source of instruction is John Playford's

*English Dancing-Master* (1651; recension by M. J. Dean-Smith, 1957), which was continued in 18 enlargements and additional volumes until 1728 and was succeeded by numerous imitations. In the early 19th century Thomas Wilson (*An Analysis of Country Dancing*, 1808, etc.) gave a new aspect to the country dance, but the revivifying effect was soon quenched by the introduction of the quadrille. A 20th-century revival of country dancing was brought about by Cecil Sharp, founder of the English Folk Dance society (1911-32).

Kennedy, *England's Dances* (1949); M. J. Dean-Smith, "Playford's English Dancing Master," three articles in *Journal of the English Folk Dance and Song Society* (1943-45).

(M. J. D.-S.)

**COUNTY**, in the United States, is the principal geographic and political subdivision of the respective states. (For the county in Great Britain and the commonwealth, *see* below.) Counties exist as geographic areas in all states, except Alaska (although they are called parishes in Louisiana), and are organized as governmental units in all except Rhode Island and Connecticut. Although organized county government blankets most of the nation, some local areas, in addition to Rhode Island and Connecticut, are without county government. Most numerous among these are certain cities, principally in Virginia but including also St. Louis, Mo., and Baltimore, Md., which are independent of the surrounding or neighbouring counties, and whose governments perform within their boundaries both city and county functions. In the 1960s approximately 3,000 organized county governments existed in the United States, the number in individual states ranging from 3 in Delaware to 254 in Texas.

The principal organ of county government is usually an elective board of commissioners or supervisors, whose members are chosen in some instances from county subdivisions or districts, and in others from the county at large. Three-member and five-member boards are most common; but where provision is made for representation of townships, board membership ranges upward to 50 and more. The term of members varies from a single year to eight years with the four-year term most common, and terms are frequently staggered. The county governing board is vested with both legislative and administrative powers. Foremost among its legislative powers are those of taxing, appropriating and borrowing money on behalf of the county, although bond issues frequently require voter approval. In addition to these fiscal powers, boards commonly possess some legislative authority of a regulatory nature, such as power to license and regulate retail liquor establishments and various forms of commercial amusement in unincorporated areas of the county. In some states county boards have zoning authority. Administrative powers usually include control and supervision of county institutions and property, letting of contracts, settlement of claims against the county, and appointment of various county officers and employees.

Elective county offices, in addition to membership on the governing board, most commonly include those of sheriff, treasurer, clerk, coroner, assessor, superintendent of schools, surveyor or engineer, and recorder or register of deeds. The local prosecutor, though in legal contemplation a state officer, is often elected from the county. Certain other county officers, such as highway commissioners, health directors and welfare superintendents, are more commonly appointed by the county board than elected. Also frequently included in the governmental organization are various special-function boards and commissions operating in such fields as agriculture, assessment, elections, hospitals, libraries and planning.

A few U.S. counties in the second half of the 20th century had managers patterned after the city managers found in many municipalities; a somewhat larger number had appointed executives with administrative authority less extensive than that of orthodox managers; and a few had elective executives similar to city mayors. The great majority of counties, however, were entirely without any single executive officer charged with general oversight of county

administration, such supervision as existed being provided by the multimember board of county commissioners or supervisors.

Major county functions are law enforcement, judicial administration, construction and maintenance of roads, provision of public assistance to the needy, and the recording of legal documents. In some states, principally in the south, the county plays an important role in school administration. Other services and institutions provided by some counties include health protection, hospitals, libraries, parks, weed control, predatory animal control, fire protection and agricultural aid.

County government is financed for the most part from local property taxes and state-aid funds, although fees and fines constitute minor revenue sources; and occasional counties levy sales taxes or other nonproperty taxes, or operate public enterprises of a revenue-producing nature.

*See* Clyde F. Snider, *Local Government in Rural America* (1957) and bibliography therein. (C. F. S.)

**Great Britain and the Commonwealth.**—In the British Isles the county (or shire) is the principal subdivision of the country for political, administrative and other purposes. Before the Norman Conquest the shire was used as a unit of government, with two principal officers—the *ealdorman* or alderman, and the *scir-gerefa* or sheriff. After the Conquest, under the name of county, the shire was administered by the sheriff and the county court; but these gradually gave way to the rising power of the magistrates in quarter sessions, who by the 18th century were the real rulers of the county. It also became the constituency for the election of knights of the shire, or county members of parliament.

In 1888 the Local Government act established county councils to take over the administrative duties of the magistrates and other functions. These councils consist of a number of county councilors (usually between 50 and 100) elected by universal adult suffrage, together with one-third of that number of aldermen chosen by the councilors, and a chairman elected by the councilors and aldermen together. They are responsible, in accordance with acts of parliament and under the supervision of central government departments, for a wide range of administrative duties, including education; services for children and old people; town and country planning; health services; maintenance of some roads; and fire brigades. The standing joint committees which administer county police forces are composed half of members of the county councils and half of county magistrates. Other services (*e.g.*, sanitation and housing) are provided by the councils of the county districts (urban and rural districts and municipal boroughs).

Apart from the county council and its officers, the chief officials of the county are the lord lieutenant and the sheriff (*q.v.*), but in both cases their functions had become by the 19th century greatly, though not entirely, ceremonial and social.

The county is also of importance as the unit for the territorial army, for sports (particularly cricket) and for the quarter sessions.

Every part of England and Wales is within a county, but for administrative purposes many of the larger towns form county boroughs and are excluded, providing their own local government services. Also, some of the counties are divided into two or three units (*e.g.*, the North, East and West Ridings of Yorkshire; East and West Suffolk); and so, while there are 52 geographical counties, there are 62 administrative counties (including the county of London) and 83 county boroughs. There are also some towns (*e.g.*, Norwich, Gloucester and Nottingham) which have been granted the status of counties in themselves and are known as counties corporate. This makes little difference in practice, and they do not necessarily have the status of county borough.

Scotland is similarly divided into 33 counties, with county councils generally resembling those of England except that they include members appointed by and from the councils of burghs within their area. County councils are also found in Northern Ireland and in the Republic of Ireland, where an adaptation of the U.S. system of council-manager government has replaced the English model.

Outside the British Isles the system of county government was adopted with variations in most of the countries settled from

Britain, including (besides the United States) Canada, New Zealand, Australia, Natal and Trinidad; in 1955 an experimental county council was established in Tanganyika. In Canada the system never became universal; where they exist, the county councils are generally much smaller than in England. New Zealand has had county councils since 1876, and by a process of subdivision the number had increased to 126 by the late 1950s. In Australia the administrative unit is generally called the shire, though the name county is used for larger areas.

**COUNTY AGENT.** As commonly used in the United States and in some other countries, the title "county agent" refers to the county agricultural representative of the agricultural extension service. In some states, this representative is known as the farm adviser or county extension director, while the title agricultural adviser is more widely used in Europe and Asia.

In countries where it is organized, the agricultural extension service is a government-supported educational service for farmers and their families. Its purpose is to keep farmers informed on the latest research-proved farming methods so that the level of agricultural production and farm family living can be improved through the adoption of these methods.

The extension service in the United States is called the co-operative extension service in agriculture and home economics, since the program is co-operatively financed and administered by the U.S. department of agriculture and the land-grant agricultural college in each state. Local funds for supporting extension work in the counties come from county tax funds or grants from farm organizations. This means that the county agent is jointly employed by the U.S. department of agriculture and the state agricultural extension service of the land-grant college in his state.

In most other countries, the extension service is administered directly by the ministry of agriculture at the national level through a system of state or provincial offices. Major religious groups contribute funds for support of the extension service in the Netherlands, while major farm organizations give similar support in the Scandinavian countries.

Regardless of the particular administrative framework of the agricultural extension service, the job of the county agent or agricultural adviser is similar in all countries. That job is to keep the farmers in his district informed about new and improved farming methods. The county agent is probably the most important local source of agricultural information. His sources of information, in turn, are the national and state agricultural experiment stations as well as private agricultural research organizations.

Nearly all county agents are graduates of an agricultural college and have had a number of years of practical experience before being employed as agents. For the most part, they have a general background in agriculture rather than a specialized background. It is not uncommon, however, for assistant county agents to be employed as specialists in a particular field. This is more usual in Europe than in the United States.

The county agent makes use of nearly all means of communication in getting current information to the farmers in his county. County meetings, tours and demonstrations are most common. In addition, the county agent prepares articles for local newspapers, appears on local radio and television programs and prepares special exhibits and displays. See also AGRICULTURAL EDUCATION AND RESEARCH; AGRICULTURAL ORGANIZATIONS. (HY. RD.)

**COUNTY CLERK,** in the United States, the chief clerical official of the county in slightly more than half the states. The clerk usually is chosen by popular election for a term of two or four years. His primary duty is that of serving as secretary to the county board of supervisors or commissioners. In this capacity he prepares the agenda for board meetings; attends meetings

and keeps minutes thereof; records ordinances, resolutions and other forms of board action; and is custodian of the board's records. Where there is no auditor or controller, the clerk commonly examines claims against the county; makes recommendation to the board concerning their payment or nonpayment; and when claims have been allowed, draws warrants upon the treasurer for their payment. In some states the county clerk serves also as clerk of one or more of the county's courts of record. Other duties assigned to his office in some states include supervision of elections; acting as registrar of voters; recording deeds and other legal documents; and issuing various licences, such as those for hunting and fishing, marriage licences and permits for the operation of commercial amusements outside municipalities. In some instances the clerk prepares the county budget and acts as county purchasing agent. As a result of his relation to the county board and the wide variety of his duties, the clerk's office tends to serve as a general clearinghouse for county business. Where his clerical and fiscal duties are most extensive, the clerk's position approaches, in some measure, that of a chief administrative officer in the county government. (C. F. S.)

**COUNTY COURT.** The most frequent use of the term county court in the United States is to designate county-wide courts of limited jurisdiction in contradistinction to courts of general, or unlimited, trial jurisdiction whose powers in the less populous areas extend to a group of counties. In this sense county courts exist in somewhat less than half the U.S. states. Actually the official legal designation is not in all cases "county court," but the territorial jurisdiction of such courts is generally coterminous with the county, and hence they are all referred to as county courts.

In some states they are courts of record; that is, they have a clerk and keep a regular docket and a systematic record of the disposition of cases.

The jurisdiction of these courts varies widely in the several states. In civil cases it ranges from a few dollars to approximately \$2,000, and in criminal cases from misdemeanors to more serious offenses carrying a stipulated penalty. In some states they have no criminal jurisdiction. In some states county courts perform nonjudicial functions along with judicial functions and in still other states they perform only nonjudicial functions. In Kentucky and Tennessee, for example, the county courts handle administrative as well as judicial functions; and in Arkansas their powers are entirely administrative and financial.

Later county-court systems set up in Virginia, Maryland, New Jersey and Missouri, and under consideration during the 1950s in several other states, were designed as a means of escaping the evils of the generally inexperienced and incompetent justices of the peace courts. The first state to take this step was Virginia in 1934. There the justices of the peace courts were in effect abolished by eliminating their trial jurisdiction and establishing for each of the counties of the state a trial justice court with jurisdiction substantially broader than that formerly accorded the justices of the peace.

**BIBLIOGRAPHY.**—Roscoe Pound, *Organization of Courts* (1940); Arthur T. Vanderbilt (ed.), *Minimum Standards of Judicial Administration* (1949); Council of State Governments, *State Court Systems*, rev. ed. (1951). (GE. W. S.)

**England.**—In England, a county court is a local court of civil jurisdiction. While the county court has ancient origins, dating from before the Norman Conquest, the institution of courts of assize under Henry II led gradually to its supersession, and the court in its modern form derives from the County Courts act 1846.

The main feature of the county courts is that they provide justice at a reasonable cost and with a comparatively simple procedure, administered by judges whose work brings them into close contact with ordinary people in the localities for which they are responsible. It was anomalous that there was until 1955 no appeal from them, unlike from judges in the high court, on questions of fact. Section 12 of the County Courts act, 1955, which has in substance been re-enacted in s. 109 and 110 of the County Courts act, 1959, authorizes appeals on questions of fact in, broadly speaking, the more important cases.

The original limit of the jurisdiction of the new courts was £20; in 1850 this was extended to £50 in actions for debt, and in 1903 to £100.

The organization and jurisdiction of county courts are now governed by the County Courts act, 1934, as amended by the Administration of Justice act, 1938, and the County Court acts of 1955 and 1959. The City of London court, though not strictly a county court, has the same jurisdiction (County Courts act, 1867, and s. 185 of the act of 1888); it was amalgamated with the mayor's court by the Mayor's and City of London Court act, 1920. The county courts proper are organized into circuits, to which one or more judges are allotted; circuits are divided into districts in each of which there is a court, with a registrar and bailiffs. The registrar is almost invariably a solicitor and hears the smaller cases as well as interlocutory matters and matters referred to him by the judge. The ordinary jurisdiction of the county court is (pecuniary limit of jurisdiction in parentheses): actions of contract or tort (where debt demand or damage claimed does not exceed £200); actions for recovery of land (where neither the value of the land nor the annual rent exceeds £100); actions in which the title to any hereditament comes in question (if the value of the land over which the easement is claimed or its annual value does not exceed £100); equity jurisdiction (£500); admiralty jurisdiction, except salvage (£300); salvage (£1,000); probate jurisdiction (£200 personalty or £300 realty); interpleader transferred from high court (£500); actions assigned to the queen's bench division of the high court, with written consent of both parties (unlimited); counterclaims, unless plaintiff gives written notice of objection (unlimited).

For a list of the acts on which this (not exhaustive) statement is founded see the *Yearly County Courts Practice*. (W. T. Ws.)

**COUP D'ÉTAT**, a French phrase (literally translated as "blow" or "stroke of state") denoting a sudden action by which an individual or group, usually employing limited violence, captures positions of governmental authority without conforming to the formal requirements for changing officeholders, as prescribed by the laws or constitution. Representative examples in French history include the overthrow of the Directory by Napoleon on Nov. 9, 1799 (18 Brumaire), and the dissolution of the assembly of the second republic by Louis Napoleon on Dec. 2, 1851. Broadly construed, the term not only describes Oliver Cromwell's forcible dissolution of the Long parliament (April 20, 1653) in England, but also applies to the Fascist march on Rome, led by Benito Mussolini, on Oct. 27, 1922; the Nazi political maneuvers of March 1933, engineered by Adolf Hitler in Germany; the termination of the third republic of France by "constitutional amendment" and its replacement by the Vichy regime with Marshal Henri Philippe Pétain as head of state in July 1940; and the Communist elimination of centres of opposition in Czechoslovakia (Feb. 1948). In a more restricted sense, a *coup d'état* merely results in the abrupt replacement of leading governmental personnel; but, unlike a revolution, neither alters basic economic and social policies nor significantly redistributes power among competing political groups. This occurrence (known in Spain as *golpe de estado*) is a regular one in Latin America, and accounted for the displacement of more than 30 presidents in South American and Central American republics between 1945 and 1960.

(M. Kg.)

**COUPER, ARCHIBALD SCOTT** (1831–1892). Scottish chemist best known for his work in organic molecular structure, was born at Kirkintilloch. He was a student at Glasgow and Paris, and became an assistant at Edinburgh. Through C. A. Wurtz, Couper submitted a paper to the French Academy entitled "On a New Chemical Theory," which developed the quadrivalent character of the carbon atom and the ability of the carbon atom to unite with itself. Because Wurtz was not a member of the Academy, the presentation was delayed until June 14, 1858. Meanwhile, on March 16, 1858, the same revolutionary basic theory was presented by Kekulé von Stradonitz. Although Couper's paper was less biased by preconceived ideas and was the first to contain formulas which pictured molecular structural relationships by continuous or dotted lines, it was ignored. As Kekulé became famous, Couper's

life, blighted by lack of recognition, became tragic. The board of lunacy of Scotland records two entrances and discharges from a mental institution. He lived in retirement, cared for by his mother, until his death March 11, 1892. A plaque placed on the house at Kirkintilloch commemorates his classic contribution.

(V. Bw.)

**COUPERIN**, the name of a French family that produced a succession of musicians from the early 17th to the mid-19th century and achieved its greatest fame through two composers of genius who were court musicians to Louis XIV.

LOUIS COUPERIN (c. 1626–1661), born at Chaumes in the province of Brie, was the first of the many Couperins to become organist at the church of St. Gervais in Paris; he also played the viol and violin in the ballet music of the court. He was a brilliant harpsichordist, and contemporary accounts suggest that his vigorous style of playing revealed the same qualities as his harpsichord compositions, which are distinguished by an almost aggressive use of dissonance and of baroque ornamentation. At the same time he had command of a sturdy contrapuntal technique recalling the French organ school of the 16th century. At times his tonal architecture, built on Italian models, and his *bel canto* melodies suggest Handel. It is significant that his finest compositions should be conceived in the transitional convention of the *chaconne* or *passacaglia*, for as a composer he is both reactionary and progressive. He died in Paris on Aug. 29, 1661.

FRANÇOIS COUPERIN (1668–1733), Louis' nephew, known as "Le Grand," was born in Paris, Nov. 10, 1668. His father, Charles Couperin, who had succeeded Louis as organist at St. Gervais, died in 1679; François inherited the post, although he did not take it up until 1685 or early 1686 and was meanwhile educated in music by an uncle, also François Couperin (1631–1701), and by the famous organist Jacques Thomelin, who gave him a thorough grounding in counterpoint. Like his uncle Louis, François is remembered mainly for his keyboard pieces, though the *Oiseau Lyre* edition of his works (1933) reveals that his chamber music and church music are also important. His first published works were two organ Masses, composed c. 1690, and long erroneously ascribed to his uncle François. In 1693 he succeeded Thomelin as one of the organists of the royal chapel and in 1694 was appointed to teach the royal children. He was ennobled in 1696 and from about 1701 performed the functions of director of music at the court, although not officially succeeding to the appointment until 1717. He kept his position as organist at St. Gervais until 1723 and his offices at court till 1730, being succeeded in both by other members of his family. He died in Paris, Sept. 12, 1733.

The personal voice beneath the traditionalism of Couperin's Masses becomes unmistakable in the succession of harpsichord pieces that he published, in four exquisitely engraved volumes, between 1713 and 1730.

Although the plan of Couperin's movements is conceived harmonically, his music marks a transitional stage between polyphony and homophony in that it usually includes a dialogue between treble and bass. Implied polyphony exists alongside the ripest development of tonal harmony, and Couperin is thus, among the late baroque composers, the nearest to Bach; this is evident in his fine trio sonatas (especially "L'Impériale" and "L'Apothéose de Corelli") and in many of the movements from the *Concerts Royaux* (c. 1714–15), which he composed for the king's Sunday evening entertainments. In his church music, as in his chamber music, Couperin achieves a fusion of the French and Italian styles, as illustrated in the early *Motet de Ste. Suzanne* (1698), which is at once voluptuous in its brilliant Italian cantilena and virginal in its harmony, rhythms and textures.

Couperin's last and greatest liturgical work, the *Leçons des Ténèbres* (1715), brings to the linear subtlety of the French vocal style and the pathos of Italian harmony a quality of ecstatic mysticism that has no parallel in French or Italian music of the period. Bach's well-attested admiration for Couperin was not fortuitous.

Couperin also wrote an important, if somewhat ambiguous and obscure, theoretical work, *L'art de toucher le clavecin* (1717).

François Couperin and the French Classical Tradition (1950); P. Citron, *Couperin* (1956). (W. H. M.)

**COUPERUS, LOUIS MARIE ANNE** (1863–1923), one of the most famous of modern Dutch novelists. Of aristocratic family, he was born on June 10, 1863, at The Hague, to which he returned after living for a time in the Netherlands East Indies. After failing as a poet, he became known in 1889 through his naturalistic novel *Eline Vere* (Eng. trans., 1892). This was followed by *Noodlot* (1891; Eng. trans., *The Footsteps of Fate*, 1891) and *Extase* (1892). Two Balkan romances—*Majesteit* (1893; Eng. trans., 1894) and *Wereldvrede* (1895)—were less successful but were praised for their evocation of atmosphere. The fairy tale *Psyche* (1898; Eng. trans., 1908) showed a new aspect of his talent, but with *De stille kracht* (1900; Eng. trans., *The Hidden Force*, 1922) he returned to realism.

Meanwhile Couperus had settled in Italy where he wrote his masterpieces—*De boeken der kleine zielen* (1901–03; Eng. trans., *The Small Souls*, 1914) and *Van oude mensen de dingen die voorbijgaan* (1906; Eng. trans., *Old People and the Things that Pass*, 1919)—describing life as he knew it in the decadent society of The Hague. His surroundings inspired him also to write a group of historical novels conveying the combined joy in living and flourishing decadence of the ancient world. These included *De berg van licht* (1905) and *Antiek Toerisme* (1911; Eng. trans., *The Tour*, 1920). During World War I he returned to The Hague and later traveled through Africa and eastern Asia, describing his journeys in a series of impressionistic newspaper sketches. His later work included, as well as many short stories, the great novels *Xerxes* (1919; Eng. trans., *Arrogance*, 1930) and *Iskander* (1920), about Alexander the Great. He died at Arnhem, July 16, 1923.

Couperus had a refined and delicate pleasure in life, but his ideas and his writings were dominated by a pessimistic determinism. His fame is based on his great narrative gifts and his precise and convincing delineation of character.

See H. van Booven, *Leven en Werken van Louis Couperus* (1933). (Gb. W. Hs.)

**COUPLET**, a pair of lines of verse, which are welded together by rhyme. In rhymed verse two lines which complete a meaning in themselves are particularly known as a couplet. Thus, in Pope's *Eloisa to Abelard*:

Then share thy pain, allow that sad relief;  
Ah, more than share it, give me all thy grief.

In French literature the term *couplet* is not confined to a pair of lines, but is commonly used for a stanza. A "square" couplet in French, for instance, is a strophe of eight lines, each composed of eight syllables. In this sense it is employed to distinguish the more emphatic parts of a species of verse which is essentially gay, graceful and frivolous, such as the songs in a vaudeville (*q.v.*) or a comic opera. In the 18th century Le Sage, Piron and even Voltaire did not hesitate to engage their talents on the production of couplets, which were often witty, if they had no other merit, and were well-fitted to catch the popular ear. This signification of the word *couplet* is not unknown in England, but it is not customary; it is probably used in a stricter and a more technical sense to describe a pair of rhymed lines, whether serious or merry. The normal type, as it may almost be called, of English versification is the metre of ten-syllabled rhymed lines designated as a heroic couplet. This form of iambic verse, with five beats to each line, is believed to have been invented by Chaucer, who employs it first in *The Prologue to the Legend of Good Women*, the composition of which is attributed to about the year 1386. That poem ends with the couplet:

And therefore may I seyn, as thynketh me,  
This song in preysing of this lady fre.

This is an absolutely correct example of the heroic couplet, which ultimately reached majesty in the works of Dryden and brilliancy in those of Pope.

**COUPLING**. When lengths of shafting are to be joined up, in factories or ships, couplings are employed, as they are also to connect a prime mover to a machine. Usually the coupling

TYPES OF COUPLINGS

(A) Flange flexible coupling, which is keyed onto each shaft; (B) split muff coupling, with key and clamping bolts; (C) universal joint coupling, providing free horizontal and vertical movement

connection is permanent; if frequent disconnections are required a clutch (*q.v.*) has preference. Flange couplings are the most often used, the end of the shaft being forged into a flange or a flange being keyed on and united to a companion one by bolts. Split muff couplings fit over each end of the shaft and are contracted by bolts, while the split compression type is also quick to apply and remove, being tightened by three bolts. These draw hoods together over the tapered exterior of a split sleeve, causing the latter to grip the shaft ends and drive without need for keys. When one shaft has to assume various angular relations a universal joint coupling is preferred, having two pivots located at right angles, and connected either through a steel member or a composition plate (see *AUTOMOBILE*). Huge universal couplings of a rather elaborate kind are needed in rolling-mill drives, to compensate for the varying heights of the rolls.

Flexible couplings on shafts are extensively utilized. They protect engines, electric motors or machines against the shocks due to variations in the driving power or in the loads; and their flexibility also allows for slight irregularities in the alignment of shafts. A favourite class is the flange coupling mentioned above, but with leather or rubber bushings surrounding the bolts in one flange, and sometimes with soft washers interposed between the faces of the flanges. Another kind has rims with interlocking lugs—these do not touch, but the drive is transmitted by rubber blocks or a long leather belt is interwoven between the lugs so as to take the drive flexibly without any metal-to-metal contact occurring. These also electrically insulate the motor from the machine which is coupled to it. Steel springs in some instances perform a like service. A coupling is employed to join up the ends of hose, being either a screw type with nut turned by a spanner, or a hand instantaneous grip, for fire hose or the brake hose of trains. The railway carriage and wagon coupling is either of hand-tightened screw type, or automatic in action.

**COURANTE** (Latin *currere*, "to run"), a running dance in 3/4 time attributed to 16th-century Italy. The musical corrente consisted chiefly of running passages of eighth notes.

The court courante originated in 17th-century France. Much in vogue for almost two centuries as a slow, grave dance, it contained, despite its nobility, some gliding and springing steps. The music was in moderate 3/2 time with occasional measures in 2/4 for rhythmic interest. Composers used both types in the suite where it followed the allemande (*q.v.*), with which it contrasted in rhythm and tempo. (L. Hr.)

**COURANTYNE** (Dutch *CORANTIJN*), a river which flows between Surinam and British Guiana, South America. The boundary runs along the British bank and British nationals have free navigation but no fishing rights. The Courantyne rises in the Acarary mountains and flows 475 mi. to the Atlantic near Nickerie. Its upper course, called the Coeroeni, is a lesser stream than the

New river which joins it. Small ocean-going vessels of a draught of 14 ft. or less may ascend 60 mi. to the first rapids at Orealla, and there is boat navigation above, but the whole basin is undeveloped and largely unexplored forest. (G. LN.)

**COURBET, GUSTAVE** (1819–1877), French painter and leader of the 19th-century Realist movement, was born on June 10, 1819, at Ornans (Franche-Comté), where his father was a prosperous farmer. In 1841 he went to Paris to study painting, nominally at various teaching studios, but more effectively by study in the Louvre of the works of Rembrandt, Hals, Velázquez and others. Some of his first paintings, especially self-portraits, are romantic in flavour, but after the mid-1840s he was painting landscapes and naturalistic figures notable for their sense of weight and tangibility. He visited Holland in 1847, which no doubt fortified him in his intention of painting, aggressively and on a large scale, subjects which to the academic eye would appear commonplace, vulgar and even subversive.

After exhibiting the huge "Burial at Ornans" (now in the Louvre) at the Salon of 1850, he became the acknowledged leader of the Realist movement, being supported by the critics J. Champfleury (for a few years) and Charles Baudelaire. He also received patronage from the comte de Morny, who in 1852 bought his "Village Girls" (Metropolitan Museum of Art, New York City). For the Exposition Universelle of 1855 he prepared "The Artist's Studio," described as a realist allegory, in which figures and objects pertaining to his own career and beliefs are solidly bodied forth. When this and the "Burial at Ornans" were refused by the jury, Courbet set up his own Pavilion of Realism containing 40 of his paintings near the exhibition palace.

He now became the rallying point of a new generation, and in the ensuing decade he was to exert a powerful influence on the work of Manet, Monet, Renoir, Camille Pissarro and Cézanne. Through his short-lived tutelage of Whistler, Courbet's influence spread even to Great Britain where, however, pure academism had already been abandoned. Courbet's other important works of 1850–60 include the "Portrait of P. J. Proudhon" (1853; Petit Palais, Paris); "The Meeting" or "Bonjour, M. Courbet" (1854; Musée Fabre, Montpellier); and the "Girls on the Bank of the Seine" (1856; Petit Palais). There are also some powerful marines and a group of rocky landscapes constructed with a grave and massive architectural sense.

After 1860 his subject matter became less doctrinaire and more sensuous and relaxed. He painted many portraits as well as flower and fruit pieces in which deep and glowing colours supersede the earthy tones of his early works. His studies of calm and raging seas are a contribution to the sea images of the romantic artists, poets and musicians of this period, while his strange groups of female nudes such as "Sleep" (1866; Petit Palais) are both sensuous and profound. By now he had overcome official opposition

and was a regular Salon exhibitor. In 1871, as a dedicated Socialist, Courbet found himself an official of the Commune, and was charged with the demolition of the column in the Place Vendôme. After six months in prison he was forced by the threat of a huge fine to leave for Switzerland where, though despondent and in failing health, he continued to paint until his death at La Tour du Peilz on Dec. 31, 1877.

See G. Riat, *Gustave Courbet, peintre* (1906); G. Boas, *Courbet and the Naturalistic Movement* (1938); Gerstle Mack, *Courbet* (1952). (D. C. T. T.)

**COURBEVOIE**, an industrial suburb of Paris in the Seine département, is situated in the Gennevilliers loop of the Seine 9 km. (5½ mi.) N.W. of Notre Dame cathedral. Pop. (1962) 59,437. The Avenue du Général de Gaulle, the chief feature of the suburb, is a continuation of the Champs Élysées. Courbevoie manufactures dyes, biscuits, gauze and cars, and fruit preserving and laundering are carried on. Formerly the garrison of the Swiss guards (the barracks were built by Axel Guillaumot in 1756–65), it was occupied during World War II by the Germans on June 14, 1940. Damaged in air raids in 1943–44, it was liberated on Aug. 25, 1944. (H. DE S.-R.)

**COURCHEVEL**, a town of southeastern France, département of Savoie, is situated high on the south side of the Isère valley, about 70 km. (44 mi.) S.E. of Chambéry. The permanent population (1954) was 170. Courchevel is a rapidly developing winter resort, divided into five settlements at different heights: St. Bon 3,600 ft., Le Praz 4,260 ft., Courchevel (lower) 5,100 ft., Moriond 5,400 ft. and Courchevel (upper) 6,100 ft. There are several types of mechanical lifts for skiers. A motor road reaches Courchevel, and the railway station of Moutiers Salins is 25 km. (15½ mi.) away.

**COURCI, JOHN DE** (d. 1219), Anglo-Norman conqueror of Ulster, was a member of a celebrated Norman family of Oxfordshire and Somerset. Sent to Ireland with William FitzAldelm by Henry II in 1176, he immediately led an expedition from Dublin to Ulster and in 1177 seized its capital, Down (now Downpatrick). He subsequently gained effective control of eastern Ulster and his firm rule there was responsible for the early prosperity of the area.

John de Courci had a perennial feud with the de Lacys, another Anglo-Norman family adventuring in Ireland, and the younger Hugh de Lacy took and held him prisoner for a short while in 1204. De Courci, perhaps by a refusal of homage, had angered King John, who in May 1205 granted Ulster to Hugh with the title of earl. De Courci, with his brother-in-law, Reginald, king of Man, laid siege to the castle of Rath (possibly Dundrum) but was routed by Hugh's elder brother, Walter de Lacy, lord of Meath. He disappeared until 1207, when he received permission to return to England. He accompanied King John to Ireland in 1210 and seems thereafter to have retained his favour. He died probably in Sept. 1219.

Both John de Courci and his wife Affreca were benefactors of the church and founded monasteries in Ulster. John replaced the secular canons of Down priory with Benedictine monks from St. Werburgh's abbey, Chester.

See G. H. Orpen, *Ireland Under the Normans*, vol. II (1911).

(A. Gw.)

**COURIER, PAUL LOUIS** (1772–1825), French Hellenist and political satirist who opposed the centralization of power under the restored Bourbon monarchy, was born in Paris, Jan. 4, 1772. He was brought up on the family estates in Touraine and early acquired a love for the classics. Courier was destined for a military career and in 1784 was sent to Paris to study mathematics and science, but he continued to devote his leisure to Greek. He entered the army in 1793 and was posted to the army of the Rhine, but his determined disrespect for authority made him an indifferent soldier and, after failing to appear at his post at Wagram (1809), he left for Italy without leave. He subsequently resigned his commission and remained in Italy until 1812.

While serving in the Italian campaigns (1798–99 and 1806–07) he had pursued his classical studies in Italian libraries and had published *Éloge d'Hélène* (1803), a free imitation of Isocrates, and

IT COURTESY OF THE METROPOLITAN MUSEUM OF ART, GIFT OF HARRY PAYNE BINGHAM, 1940  
"VILLAGE GIRLS" BY GUSTAVE COURBET; c. 1852. IN THE METROPOLITAN MUSEUM OF ART, NEW YORK CITY

an edition and translation of Xenophon's treatises on the command of cavalry and horsemanship (1807). In 1809 he discovered a manuscript of Longus' pastoral *Daphnis et Chloé*, containing a passage previously unedited, in the Laurentian library at Florence and published an edition and translation into a French full of archaic idiosyncracies in 1810. Its value was later the subject of controversy, because an ink blot he had made on the manuscript obscured part of the passage and made his version unverifiable.

After his return to France, Courier settled on his estate at Vêretz (Indre-et-Loire), with frequent visits to Paris. His earlier *Lettres de France et d'Italie* (1787–1812) had revealed a keen sense of irony, fixed opposition to the empire and an original and lively style. He then developed these in a series of political pamphlets, beginning with the *Pétition aux deux chambres* (1816). In this he made local resentment at the tyrannies of the restored bureaucracy in Touraine the occasion for a vigorous attack on the Bourbon monarchy, typically invoking political principle in a personal cause. His *Simple Discours de Paul Louis* . . . (1821), a powerful plea against the proposal to purchase the estate of Chambord for the duke of Bordeaux, is in the same vein. It led to a brief imprisonment; his subsequent account of his trial achieved great success. A series of letters to the *Censeur Européen* (1819–20) advocated a liberal monarchy; Courier's conception of liberalism was based on a strong sense of individual prerogative. Other pamphlets included *Livret de Paul Louis* and *Gazette du village* (both printed anonymously in Brussels, 1823) and *Pamphlet des Pamphlets* (1824). Courier was found shot in the forest of Larçay near his home on April 10, 1825, and the murder, long unsolved, was eventually brought home to his own servants.

Courier is chiefly valued for the trenchancy with which he expressed a typical Gallic attitude to political affairs, for the brilliance of his satire and for his polished, incisive style, erudite but never obscure.

**BIBLIOGRAPHY.**—There have been many modern editions of individual works; the most useful collected edition is by R. Gaschet, 2 vol. (1925), which includes a biography. *Pamphlets politiques* were edited with preface and notes by J. Isormi (1947). The *Daphnis et Chloé* is included in the *Collection des classiques français* (1955). See also R. Gaschet, *La jeunesse de P. L. Courier* (1911), *P. L. Courier et la Restauration* (1913) and *Les Aventures d'un écrivain* (1928); and J. O. Fischer, *Žáci francouzské revoluce* (1950).

**COURLAND** (Latvian *KURZEME*), the land of the people known to medieval chroniclers as Curi or Cori (in Latvian: Kursi); namely, the southwestern part of Latvia, to the south of the river Daugava (Duna, Dvina), on the west extending over the main part of Latvia's seashore on the Baltic. The Curi are first mentioned in Rimbert's *Vita S. Ansharii* (c. 875). At that time they already possessed a comparatively large territory with several organized subdivisions and a royal capital and had withstood Swedish expansion (early in the 7th century). Later they launched their own raids, menacing the Danish and Swedish shores (according to Nordic sagas). If forced at times to accept Swedish sovereignty, they shook it off. Adam of Bremen (writing c. 1075) describes them as rich, powerful, merciless, and possessing some important religious centres. Saxo Grammaticus (c. 1150–c. 1220) tells stories about several of their kings, and Henricus de Lettis (early 13th century) gives a colourful description of the fierce attack of the Curish fleet on the newly built town of Riga. In the 13th century, however, German crusaders subjugated the country. The last Curish king, Lammekinus, sought to elude direct pressure from the Knights of the Sword, otherwise known as the Livonian Order, by submission to the papal legate Baldwin of Aulnes in 1230.

Another warlike Latvian tribe was that of the Zemgali or Semigallians (called Simkala in a runic inscription of about 1040), who inhabited the fertile valley of the Lielupe river (the Kurländische Aa). Contemporary chronicles describe how they struggled for three generations to free themselves from the Order, but information about their earlier history is scant. Two facts, however, must be stressed. First, the Hypatian (Ipatiev) chronicle describes the heavy defeat suffered by the princes of Polotsk at the hands of Semigallians in 1106. Secondly, Henricus de Lettis

relates how the western invaders had to beg Pope Innocent III to excommunicate those who traded with the Semigallians by the way of Portus Semigallorum (on the estuary of the Lielupe). Thus on the one hand the Semigallian state was strong enough to stop Russian penetration, while on the other its Baltic trade jeopardized certain ambitions of the newcomers from the west.

On the dissolution of the Livonian Order (1561), its last master, Gotthard Kettler, preserved the independence of Courland as a duchy under the formal suzerainty of Poland (1562), which ended with the third partition of Poland in 1795. The conditions under which the Latvian peasantry lived were rather hard, but the existing social order was vital enough to achieve extraordinary progress under Gotthard's grandson Jacob, the ablest of all the Curish dukes (sole ruler 1642–82). Jacob developed local industry, fostered foreign trade and created not only a sizable merchant fleet but also a navy of warships. He moreover acquired two colonies: the island of Tobago in the West Indies (1645) and Gambia, at the mouth of the Gambia river, on the West African coast (1651). Development was cut short, however, by the Swedish-Polish war of 1655–60, during which Jelgava (Mitau), the capital of the duchy, was stormed and pillaged by the Swedish army. The duke himself was made captive, but he returned to Courland and resumed his reign after the peace of Oliva.

Trouble came with the dynasty of the Birones (1737–95). Ernst Johann Biron (q.v.), who was elected duke on the extinction of the Kettlers in 1737, exercised great power in the Russian empire till court intrigues caused his downfall and long exile (1741–63), during which the duchy was governed by the ducal council and from 1758 by Charles of Saxony, a younger son of Augustus III of Poland. Restored to the duchy in 1763, Biron abdicated in 1769. His son Peter (d. 1800), the last reigning duke, founded the Academia Petrina in Jelgava (1775) but was dispossessed at the partition of Poland in 1795.

The Russian domination brought at first little change, as Catherine the Great strove to secure her rule over this frontier province (*gubernya*) and showered favours on its ruling class. Moreover, though the peasantry's situation was anything but splendid, Courland in the 16th and 17th centuries had already become known as a cultural centre, with such eminent writers as G. Mancelius, C. Furecker (Fuereccerus) and others. Similarly in the 19th century it was the cradle of the Latvian literary language and the homeland of Krisjanis Valdemars, promoter of the Latvian revival, and of many other Latvian political and cultural figures.

With the proclamation of Latvian independence in 1918, Courland became part of the new state; for subsequent developments see LATVIA.

See works cited under LATVIA; also A. V. Berkis, *The Reign of Duke James [i.e., Jacob] in Courland 1638–1682* (Vaidava, Lincoln, Neb., 1960). (A. Sp.)

**COURNAND, ANDRÉ FRÉDÉRIC** (1895– ) French-U.S. physician and physiologist, co-winner of the Nobel prize in medicine in 1956, together with Dickinson W. Richards and Werner Forssmann, for work that opened a new era in heart research. Cournand was born in Paris, France, Sept. 24, 1895, and received his M.D. degree from the University of Paris in 1930. In the same year he settled in New York city to seek further training at Bellevue hospital in diseases of the chest. There he met Richards, with whom he collaborated for the next 25 years in studies of diseases of the lungs and heart. It was necessary for them to develop new techniques in order to increase the precision of their measurements of lung and heart function. They learned of Forssmann's experiment in which he passed a tube through a vein into his own heart and adapted this direct approach to measure the amount of blood the heart pumped and the pressures under which it performed. As a result of their perfection of this technique, now termed cardiac catheterization (q.v.), it became possible to study the conditions under which the human heart laboured in disease and to make more accurate diagnoses of the underlying anatomic defects. Cournand became a member of the Columbia university college of physicians and surgeons in 1934 and held the rank of professor after 1951. He became a naturalized citizen of the U.S. in 1941. (R. M. Hy.)

**COURNOT, ANTOINE AUGUSTIN** (1801–1877), French economist and mathematician, was a pioneer in mathematical economics. He held teaching and administrative posts at several academies and universities and was French inspector general of studies. Cournot was the first economist who, with a competent knowledge of both subjects, endeavoured to apply mathematics to the treatment of economic questions. His *Researches Into the Mathematical Principles of the Theory of Wealth* (Eng. trans. by N. T. Bacon, with a bibliography of mathematics of economics by Irving Fisher, 1897) was published in 1838. The foundations of the mathematical treatment of economic questions laid by Cournot provided the essential basis of much of the work of later economists. He was concerned primarily with an analysis of partial market equilibrium based on the assumption that participants in the process of exchange are either producers or merchants whose end is the maximization of money profit. He therefore ignored the concept of utility. His most important contributions were his discussions of supply and demand functions and of the establishment of equilibrium under conditions of monopoly, duopoly and perfect competition; his analysis of the shifting of taxes, which he treated as changes in the cost of production; and his discussion of problems of international trade.

Although his chief contributions were in the field of mathematical economics, he was a fruitful philosopher. In this latter field he was pre-eminently a protagonist of the theory of chance occurrences.

See Irving Fisher, "Cournot and Mathematical Economics," *Quarterly Journal of Economics*, vol. xli, pp. 119–138 (1897–98).

**COURSING**, the pursuit of game by hounds hunting by sight and not by scent, was fully described about A.D. 150 by the Greek philosopher and historian, Arrian, in his *Cynegeticus* (trans. by W. Dansey, 1831). Dogs bearing a strong resemblance to the modern greyhound are shown in carvings, paintings and inscriptions found on the tombs of the early Egyptian kings, and excavations in Mesopotamia date domesticated greyhounds prior to 5000 B.C. The New York Metropolitan Museum of Art has a wall painting from an ancient Egyptian tomb showing greyhounds hunting gazelles. The greyhound was bred by the Egyptian kings to hunt the wild hare also, much like the coursing of the same breed of dogs with hares in Great Britain, the United States, Australia and in other parts of the world. Coursing is known as one of the most ancient of British sports, purportedly introduced into Britain by the Phoenicians during early trading voyages or by the Cretans about 500 B.C.

The sport became very popular in England, Ireland and Scotland during the reign of Queen Elizabeth I (1533–1603), and in this period the first known set of rules was drawn up by the duke of Norfolk. The "laws of the leash," as they were called, laid down the principles upon which the sport has since been based, and established coursing as a series of competitions between two greyhounds at a time pursuing one hare. The dogs are judged on performance, as well as on their success in catching the hare; points are awarded for outracing the other dog and catching up with the hare, for turning it at a right angle, for wrenching (turning it at less than a right angle), for tripping the hare and for a kill.

The first known coursing club came into existence in 1776 at Swaffham, through the enterprise of Lord Orford. Progress of the sport led to the creation of the National Coursing club in 1858, but by that time the Waterloo cup, the Derby of coursing, had been well established. It started in 1836 and is held annually at Altcar, the estate of the Earl of Sefton, near Liverpool. It was named for the Waterloo hotel in Liverpool, where the first promoters met. Originally there were only 8 entries, since doubled to 16, then 32, and finally 64. The *Greyhound Stud-Book* was instituted by the National Coursing club in 1882. (A separate stud book was established by the Irish Coursing club in 1923.)

Coursing was taken to the United States early in the 19th century and led to organization of the American Coursing board, which governed the sport from 1886 to 1906, when the National Coursing association (N.C.A.) came into being. Spring and fall coursing meetings are held by the association in Abilene, Kan. The Ameri-

can Field cup was established in 1886, followed by the Columbus cup in 1893, and the National Waterloo cup in 1895, named for its British counterpart and still contested annually.

The N.C.A.'s *Greyhound Stud Book*, established in 1906, also is the stud book for the sport of greyhound racing with a mechanical lure, the outgrowth of coursing. See also DOG RACING.

See H. Edwards Clarke, *The Modern Greyhound* (1947); E. C. Ash, *The Book of the Greyhound* (1954). (G. C. Mo.)

**COURT, ANTOINE** (1695–1760), minister of the French Reformed Church who restored Protestantism in his country after its proscription by the revocation of the Edict of Nantes (1685), was born in the province of Vivarais. By 1700 the Huguenots were disorganized, their ministers were exiled or dead and the revolt of the Camisards and the persecution of the Dragonnades had turned the leaderless Protestants to religious fanaticism. In many places Protestants turned despairingly to attending Mass, though afterward praying together secretly. The young Court determined that disorder, religious fanaticism and apostasy must be rooted out. He traveled in Languedoc and Vivarais preaching order and restraint. His purposes were to instruct people through religious assemblies, to combat fanaticism by introducing healthier religious ideas, to re-establish the consistorial discipline of the Reformed Church and to train young ministers. He began with a small gathering at Monoblet, Gard, in Aug. 1715—the first provincial synod of the Reformed Church of France since 1685. The synod decided that wherever congregations were re-established elders should be elected to oversee them, to assist ministers by finding safe refuges and guides and to collect money for the poor and prisoners. Also the synod decreed that women must not preach, that Scripture must be the only rule of faith and that aid was to be forbidden to those who rushed blindly into danger; these rules clearly rejected fanaticism. Court was ordained in Nov. 1718 by his coadjutor Pierre Corteiz, himself ordained the previous year in Switzerland. Other synods followed, and after 1724 their increasing activity brought determined persecution. Court steadfastly refused to rebel and withdrew several times to Switzerland, where eventually he settled at Lausanne, acting, until his death there on June 12, 1760, as director of a seminary for training ministers for the "Church of the Desert," the Reformed Church in France. He wrote *Histoire des troubles des Cévennes ou de la guerre des Camisards* (1760) and left a large correspondence and other materials in manuscript, preserved in the public library at Geneva.

See E. Hugues, *Memoires d'Antoine Court* (1885); E. and E. Haag, *La France Protestante*, vol. iv (1884). (B. H.)

**COURT** originally denoted an enclosed place and is still used in this architectural sense. It is aptly used as a term for judicial tribunals, which originally were enclosures within which sat the judges and their officials, while counsel, attorneys and the general public stood outside the bar of the court. In England the expression "called to the bar" is applied to barristers upon qualifying to practice. Similarly, senior barristers or queen's counsel are permitted to come "within the bar of the court." At first these enclosures were temporary structures in the open field; later, fixtures in a large room or hall.

In Europe, in the early middle ages, before the separation of judicial from legislative and administrative functions, the king and his chief councilors sat in his palace for the exercise of all these functions, and so the household of the king was also called "the court." Since all judicial authority was derived from the king, his presence was assumed in all the specialized courts, each of which was regarded as the *curia regis* ("king's court") itself.

Under the influence of feudalism, some institutions, originally public or royal, fell into private hands and finally became the property of a lay or ecclesiastical magnate who would preside, in person or by deputy. The owner was not, however, a judge: he conducted the proceedings and announced the result, but the court of suitors (i.e., certain landowners who, because of their holdings, owed "suit of court" and were obliged to act as its judges) itself decided by what ordeal the case should be tried. When appellate proceedings ensued, it was sometimes difficult to say who had been responsible for a "false judgment," the court

and its suitors or the presiding officer, who might be a local official, a sheriff, count or margrave, or the owner of a seigniorial court. (See COURT BARON; COURT LEET.)

From the 12th century onward the increasing number of university-trained civilians and canonists created a recognized legal profession, and it became the rule for bishops and others to commit their judicial powers to their "officials" and to appoint "delegates" to review their decisions. The English kings appointed professional "justices," and the church's highest central court, the rota, was formed of professional lawyers. Many Italian cities conveniently accessible to university graduates in law took the opportunity to use these professionals to man their own courts and even incorporated them as a "college of justice." This term was employed when a somewhat similar court was set up in Scotland in 1532. The rise of the legal profession also determined the gradual separation of judicial from administrative functions. Thus, in England, many of the considerable powers of the justices of the peace in quarter sessions were transferred to the new county councils as late as 1888, by which time it had become an anomaly for an essentially judicial institution to levy tax rates, for example.

### ENGLAND

England's oldest courts, those of manors, hundreds, counties and even the house of lords, seem to have consisted of suitors who in the course of time were replaced by their clerks (1846 in the new county courts; 1876 by professional judges added to the house of lords). The history of courts in England is one of steadily growing specialization, sometimes along lines of subject matter, sometimes of procedure. It might be too much to say that all the modern courts sitting in England may be traced back to a common origin, but the higher courts are all offshoots from the *curia regis*. (See COMMON PLEAS, COURT OF; EQUITY; EXCHEQUER; HIGH COMMISSION; COURT OF; PRIVY COUNCIL, JUDICIAL COMMITTEE OF; QUEEN'S BENCH, COURT OF; STAR CHAMBER.)

The courts exercising jurisdiction in England are divided by certain features which may be briefly indicated. A distinction may be made first between superior and inferior courts. Superior courts are the court of appeal and the high court of justice (comprising the chancery division, the queen's bench division and the probate, divorce and admiralty division), in which must be included the courts presided over by the itinerant commissioners of assize who are usually judges of the high court, specially commissioned for each assize (*q.v.*). There are also the court of criminal appeal, the courts-martial appeal court and the central criminal court. The inferior courts are the local or district courts; namely, county courts and magistrates' courts (see below). Superior courts are also known as courts of record because their proceedings are enrolled and definitive.

Secondly, courts may be distinguished as civil or criminal (see below). A third distinction is to be made between courts of first instance and courts of appeal. In the former the first hearing in any judicial proceeding takes place; in the latter, judgment of the first court is brought under review. Of the superior courts, the high court of justice, except as mentioned below, is a court of first instance. Over it is the court of appeal, and over that again the house of lords. The queen's bench division of the high court of justice also exercises powers of reviewing the decisions of the vast variety of statutory tribunals which make decisions affecting the rights of the subject. This is done by orders of prohibition, which restrain these tribunals from acting, orders of mandamus, which order these tribunals to act, and certiorari, which bring up the decisions of such tribunals and quash them in proper cases. The divisional court is also concerned with appeals from magistrates' courts. It will be convenient to take the division into criminal and civil courts and to outline the principal tribunals in each category.

**Criminal Courts.**—Magistrates' Courts are courts of summary jurisdiction, presided over by justices of the peace or, in London and a few of the larger towns, by legally qualified stipendiary magistrates. These courts deal with all criminal offenses except those which warrant serious punishment. An appeal lies from

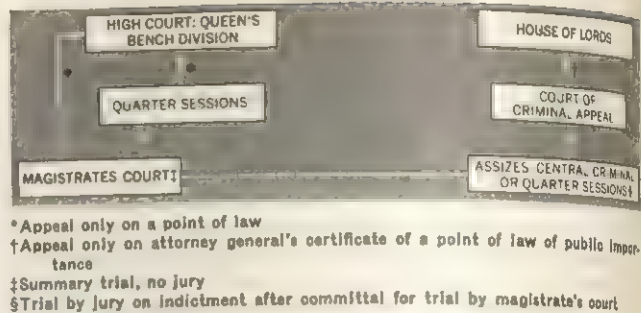

FIG. 1.—FLOW OF CRIMINAL CASES IN ENGLISH COURTS

the decision of magistrates' courts by way of rehearing to quarter sessions or by way of case stated on a point of law to the divisional court of the queen's bench division. (See MAGISTRATES' COURTS.)

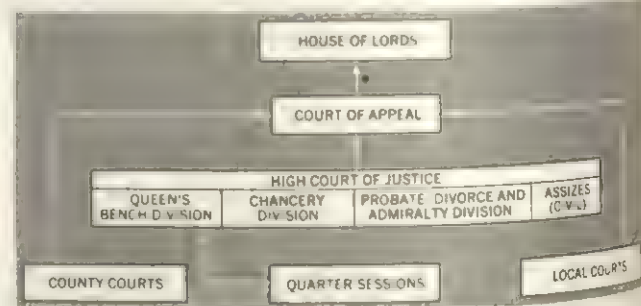

**Courts of Quarter Sessions.**—Apart from the appellate jurisdiction referred to above, quarter sessions have an original jurisdiction in most serious offenses and trial is by jury. The court is presided over by justices of the peace, whose chairman in effect exercises the powers of a judge and is usually legally qualified. For the purpose of the appellate jurisdiction of the court, the justices sit as an appeals committee. (See QUARTER SESSIONS, COURT OF.)

**Courts of Assize.**—Some of the most serious offenses, such as murder, can be tried only by the commissioners of assize. Trial before the assize courts is by judge and jury. The court of assize for London is the central criminal court, held at the Old Bailey.

**Court of Criminal Appeal.**—There is an appeal from courts of assize and courts of quarter sessions to the court of criminal appeal (see CRIMINAL APPEAL, COURT OF).

**House of Lords.**—On important points of law there is a further appeal from the court of criminal appeal to the house of lords, and also, under the Administration of Justice act, 1960, from any decision of a divisional court of the queen's bench division in a criminal cause or matter.

**Civil Courts.**—Magistrates' Courts have civil jurisdiction in a very few cases of small claims and also have very wide jurisdiction in cases of disputes between husband and wife.

\*Leave is necessary for appeal

FIG. 2.—FLOW OF CIVIL CASES IN ENGLISH COURTS

County Courts have jurisdiction in civil disputes up to quite substantial amounts and also have jurisdiction in matters such as bankruptcy and by virtue of various special enactments (see COUNTY COURT).

**The Supreme Court.**—Such civil cases as are not within the jurisdiction of magistrates' courts and county courts can only be tried by the high court of justice, which here includes commissioners of assize. The supreme court of judicature consists of the two permanent divisions already referred to, namely the high court of justice and the court of appeal. By the effect of the Judicature acts the former inherits the jurisdiction of the court of chancery and the common-law courts, the courts of probate and divorce and admiralty, and the court of pleas at Lancaster and Durham. (See also COURT OF APPEAL; HIGH COURT OF JUSTICE.)

**The House of Lords.**—As already mentioned, there is an appeal by leave from the court of appeal to the house of lords, the juris-

diction of which in appellate matters is exercised by the law lords. These consist of salaried lords of appeal in ordinary, on whom life peerages are conferred on appointment, and other members of the house of lords who hold or have held high judicial office. The appellate jurisdiction of the house of lords extends to appeals from the inner court of session in Scotland, to appeals from the court of appeal in Northern Ireland, as well as to appeals from the court of appeal in England and Wales. The law lords and certain other judges also sit as the judicial committee of the privy council to advise the sovereign upon appeals from parts of the commonwealth and from various domestic tribunals.

(P. E. L.; X.)

### UNITED STATES

The structure of court organization in the United States reflects the division of functions characteristic of the federal form of government. Each state has its own independent, comprehensive system of courts, capable, as a whole, of adjudicating almost every conceivable controversy, and subject, ordinarily, to no higher judicial authority. At the same time, there exists a system of national courts, established to perform distinctively national functions. To a considerable extent the state and national (or federal) courts exercise concurrent jurisdiction; but in certain cases the federal courts have exclusive jurisdiction, and in matters of national law they exercise the supreme judicial power.

**Federal System.**—Two short sections of the U.S. constitution provide for the establishment of a federal system of courts and define the federal judicial power. The judicial power is vested "in one supreme Court, and in such inferior Courts as the Congress may from time to time ordain and establish." The judges are appointed by the president, with the advice and consent of the senate. They hold office "during good Behaviour"—i.e., they can be removed only by impeachment—and their compensation cannot be diminished during their continuance in office.

The federal judicial power extends to nine classes of cases: (1) all cases, in law or equity, arising under the constitution, the laws of the United States, and treaties made under their authority; (2) all cases affecting ambassadors, other public ministers and consuls; (3) all cases of admiralty and maritime jurisdiction; (4) controversies to which the United States is a party; (5) controversies between two or more states; (6) controversies between a state and citizens of another state; (7) controversies between citizens of different states; (8) controversies between citizens of the same state claiming land under grants of different states; and (9) controversies between a state, or the citizens thereof, and foreign states, citizens or subjects.

The power granted with respect to the 6th and 9th classes of cases was narrowed in 1798 by the 11th amendment, which withdrew from the federal courts jurisdiction of suits against a state by citizens of another state or by foreign states and their citizens or subjects.

The supreme court has original jurisdiction of all cases affecting ambassadors, other public ministers and consuls, and of cases in which a state is a party. In the other enumerated cases, its jurisdiction is appellate and is subject to congressional regulation.

In addition to the courts thus provided for, congress has power to establish courts with plenary jurisdiction for the District of Columbia and other federal territories.

FIG. 3.—FLOW OF CASES IN U.S. FEDERAL JUDICIAL SYSTEM

Implementation of the judicial article of the constitution was a major task of the first congress in 1789. After providing that the supreme court should consist of a chief justice and five associate justices, that congress made the historic decision to establish a system of inferior courts instead of relying entirely on the state courts, in the first instance, to decide cases within the federal judicial power. The supreme court has been continuously in existence, its membership varying from six to ten, but since 1869 it has been composed of a chief justice and eight associate justices. The plan for inferior courts has undergone changes from time to time, notably in 1891, when circuit courts of appeals were established, and in 1911, when the old circuit courts, which shared original jurisdiction with the district courts, were abolished. Under the organization in existence in the early 1960s, the court of first instance was the district court, the country being divided into 88 districts. The districts are grouped into 11 judicial circuits, in each of which is a court of appeals with jurisdiction to review decisions of district courts within its territory. The membership of the courts of appeals varies from three to nine judges. The supreme court opens its term in the District of Columbia on the first Monday in October of each year, exercising the original jurisdiction vested in it by the constitution, a limited jurisdiction to review directly the decisions of district courts, a largely discretionary jurisdiction to review decisions of the courts of appeals and a limited jurisdiction, also largely discretionary, to review decisions of state courts. Since 1925 the supreme court has been able to limit its appellate work to cases which are important to the national interest or to the administration and development of the law.

Congress has also established certain specialized courts, such as the court of claims, the customs court, the court of customs and patent appeals and the tax court.

Contrary to popular supposition, the supreme court is not the court of last resort on all questions of law. It is only when some provision of the federal constitution, or an act of congress, or a treaty is involved, or some right under federal law is asserted, that the supreme court has power to review decisions of state courts. Even this limited power of review, though it was established in the first Judiciary act (1789), was repeatedly challenged by the states during the 19th century, despite the supreme court's definitive decision upholding its constitutionality in *Martin v. Hunter's Lessee*, 1 Wheat. 304 (U.S. 1816). In the great majority of cases, which involve only questions of common law or local statute, no appeal lies to the United States supreme court.

In a typical year in the early 1960s the supreme court disposed of more than 1,000 cases. In most of these it declined, after study of the records, to exercise its power of review. About 200 cases were disposed of on the merits, roughly half with full written opinions by one or more justices. Only a few original cases were involved. Of those in the appellate category, slightly more than half came from the federal courts of appeals and slightly less than half from state courts; the remainder came directly from district courts and from specialized federal courts.

In the same year, the 11 courts of appeals disposed of almost 3,000 cases, consisting primarily of appeals from district courts but including also appeals from certain administrative agencies and a few original proceedings. The district courts disposed of more than 110,000 cases. The largest single category consisted of prosecutions for violation of federal criminal laws (about 37,000); the second largest (32,000) consisted of bankruptcy cases (bankruptcy being one of the subjects concerning which the federal congress exercises legislative power). In some 20,000 cases the United States or a federal officer was a party. In the remaining category of private civil litigation (21,000 cases), about 60% were controversies between citizens of different states, about 30% arose under federal law and about 10% were in admiralty (see also SUPREME COURT OF THE UNITED STATES, THE).

**State Systems.**—Comparison of the judicial establishments in the U.S. states yields a bewildering variety of arrangements and nomenclature, and any attempt to describe a "typical" system of state courts would be misleading. Nevertheless, basic similarity is sufficient to justify an abstraction which, while not faithfully

reflecting the judicial organization of any state, will serve to illustrate the common features of most. Occupying the central place in the system is the local court of general original jurisdiction, exercising substantially plenary judicial powers. This may be called the district, or circuit, or superior court, or by any one of half a dozen other names. Modeled generally after the English court of queen's bench or the court of common pleas, and usually combining also the jurisdiction of the court of chancery, it exercises a general civil jurisdiction in law and in equity, as well as a general criminal jurisdiction. At the apex of the structure is a supreme court, although it is not always so called, with jurisdiction which is almost exclusively appellate. In some states, intermediate appellate courts have been established, often with appellate jurisdiction distinct from that of the supreme court; but the supreme court usually has final power to review decisions of the intermediate court. Apart from the local court of general original jurisdiction, there are numerous special and inferior courts of first instance with limited jurisdiction, from which appeals lie, ordinarily, to the court of general jurisdiction: probate courts, criminal courts, county courts, justices of the peace, and so on. In the larger cities municipal courts have almost completely replaced justices of the peace, and special-purpose courts, such as those for the handling of juvenile offenders, family problems and small claims, are becoming common. In contrast to the federal practice, the prevailing method for the selection of state judges is popular election. (For the courts of particular states, see the *Government* sections of the individual state articles.)

**Administration.**—The multiplicity of courts within a state, often with vaguely defined jurisdictional differences, has been a source of wasteful litigation and sometimes of injustice. To a considerable extent the hardships have been ameliorated by laws providing for transfer to the appropriate court of actions improvidently filed. Other features of the system, however, have called for stronger measures of reform. State and federal courts alike have shared the basic characteristics of independence and localism. The courts of first instance have operated independently of each other and free from any central administrative control; they have operated, indeed, in ignorance of the volume, character and distribution of judicial business within each system. Modern reform measures have therefore been concentrated upon the elimination of jurisdictional differences, the establishment of central administrative control over the assignment of judges and the dispatch of business, the systematic study of the business of the courts and the related problem of the selection and tenure of judges.

**Federal Reforms.**—The first effective step in improving the administration of the federal courts came in 1922 with the establishment of the Conference of Senior Circuit Judges (later the Judicial Conference of the United States). In 1939 the administrative office of the United States courts was established to assist the Judicial conference in its task of surveying and expediting the business of the courts. In addition there are annual conferences of all the district judges in each circuit, and semiannual meetings of the Judicial councils, consisting of all the circuit judges within each circuit. The principle that federal judges should assume an executive responsibility for the work of the federal courts as a whole, although opposed in the 1920s, has become firmly established.

**State Reforms.**—Several states have taken similar action to bring efficiency into judicial administration. A striking advance was made in New Jersey with the adoption of the constitution of 1947, which simplified and modernized an antiquated judicial system, vesting important administrative and rule-making powers in the courts.

Despite progress of this kind in some quarters, and despite comparable progress in the simplification of judicial procedure, the major problem of the courts in the 1960s was that of delay in the administration of justice. Especially in metropolitan areas, and particularly in cases in which jury trial was required, calendars were typically congested to such a point that years rather than months elapsed between the commencement of an action and

its trial. There remained a clear need for improvement in the organization of courts, in judicial procedure and in methods of selection and tenure which would ensure capable and efficient judges who would be removed from political influence.

See JUDICIARY AND COURT OFFICERS; APPEAL. For the courts of other countries, see the articles devoted to the law of particular nations, such as GERMAN LAW, SCOTS LAW, etc., as well as the *Administration* sections of the individual country articles. See also references under "Court" in the Index volume. (B. C.)

**COURTAULD**, the name of a British family of manufacturers. George Courtauld, of Huguenot descent, first introduced silk throwing (spinning) into Essex. His eldest son, Samuel (1793–1891), established a silk manufacturing firm in Essex in 1816. Brothers George and John joined the firm in 1825. Originally silk throwsters, the brothers became weavers of crepe and other silk fabrics. In 1891 the firm became Samuel Courtauld and Company, which later became the great firm of Courtaulds, Ltd. The Courtaulds acquired the British right to the viscose process for manufacturing rayon yarn and entered the artificial silk trade in 1904. They entered the rayon industry in the United States by founding the American Viscose company in 1909. Samuel Courtauld (1876–1947), a great-nephew and namesake of the principal founder, was chairman of the board of Courtauld's from 1921 to 1946, and founded the Courtauld Institute of Art. His cousin, Samuel Augustine Courtauld (1865–1953), was a director of the Courtauld firm for many years. (H. J. So.)

**COURT BARON**, the *curia baronis* ("baron's court"), is a later lawyer's name for the medieval manorial court or *halmoot* which any lord could hold for and among his tenants. By the 13th century, the steward of the manor, a lawyer, usually presided; in origin, the suitors of the court, the doomsmen, acted as judges, but the growing use of juries rendered their function obsolete. In the 17th century Sir Edward Coke distinguished two forms of the manorial court: the court baron for free tenants, the customary court for the unfree. There is no more evidence that this distinction existed in the 12th and 13th centuries than that a court baron was at that time separately constituted from a court leet (*q.v.*). The manorial court might meet every three weeks and dealt with personal actions between its suitors. The lord had considerable power over his unfree tenants, but over the free he had only a civil jurisdiction, increasingly diminished by the growing use of royal writs. Much of the business of the court was to administer the "custom of the manor" and to admit copyhold tenants. The proceedings were recorded on the court roll. See also MANOR.

See F. W. Maitland (ed.), *Select Pleas in Manorial and Other Seigniorial Courts* (1889); F. W. Maitland and W. P. Baildon (ed.), *The Court Baron* (1891).

**COURT DE GEBELIN, ANTOINE** (1725–1784), French scholar and author of *Le Monde primitif, analysé et comparé avec le monde moderne*, 9 vol. (1773–82), a half-finished study of language and mythology considered as the key to the understanding of antiquity. Born at Nîmes, Jan. 25, 1725, he followed his father, Antoine Court (*q.v.*), as a pastor of the Reformed Church. In spite of later literary preoccupations, he remained a tolerant champion of Protestantism, as in *Les Toulousaines* (1763); despite considerable Protestant hostility resulting from his standing with those at court, and even before fame and a royal appointment (1781) confirmed his position, he pleaded against injustices. With Benjamin Franklin and others he supported American independence in *Affaires de l'Angleterre et de l'Amérique* (1776 et seq.). He died in Paris, May 12, 1784.

See C. Dardier, *Court de Gebelin* (1890).

**COURTEEN** (COURTEN, or CURTEEN), SIR WILLIAM

(1572–1636), English merchant and shipowner, was born in London, the son of a Protestant refugee who had come there in 1568. From an early age William acted as the agent in Haarlem for his father's silk and linen business. He became senior partner in the merchant house of Courteen and Moncy in 1606. His trade with Europe, Guinea and the West Indies brought him great wealth, and in 1622 he was knighted. One of his vessels discovered an island which he named Barbados and to which in 1625 he sent colonists. But James Hay, earl of Carlisle, claiming a lease of all Caribbean islands under deeds of 1627 and 1628, seized Barbados in 1629. This entailed heavy losses on Courteen, as did also large loans made to James I and Charles I. He also suffered trading failures in the East Indies and long, unsuccessful litigation over the estate with one of his partners. Though still wealthy, he never recovered his former prominence. Finally, two of his ships sent to China were lost. Courteen was twice married. He died in London in late May or early June 1636. (S. R. Bt.)

**COURTELINE, GEORGES** (real name GEORGES VICTOR MARCEL MOINEAU) (1858–1929), French writer best known for his satirical comedies, was born at Tours, June 25, 1858, the son of a legal reporter who also wrote *vaudevilles* (light comedies). He served in a cavalry regiment and later worked at the ministry of religious affairs, beginning as a clerk, but left in 1894, having published several novels and short stories: *Les Gaietés de l'escadron* (1886; dramatized, 1895), *Les Femmes d'amis* (1888), *Le Train de 8 h. 47* (1891), *Messieurs les Ronds-de-Cuir* (1893; Eng. trans. *The Bureaucrats*, 1930) and *Ahl Jeunesse!* (1894). He later published *Les Linottes* (1912) and *La Philosophie de Georges Courteline* (1917) and had many plays produced, including *Lidoire* (1891), *Boubouroche* (1893), *Un Client sérieux* (1896), *La Peur des coups* (1894), *Le Commissaire est bon enfant* (1899), *La Paix chez soi* (1903) and *La Conversion d'Alceste* (1905). Courteline's works present a most colourful and truthful picture of his day: he observed and portrayed barrack-room life, office life and the daily life of the average Frenchman with shrewdness and accuracy, though his powerful sense of humour often served to conceal his basic bitterness. He possessed a gift for creating real human characters (e.g., Boubouroche, Captain Hurluret, Sergeant-major Flick, Old Soupe, etc.) and his style, of quite classic perfection, was rich, vivid and expressive. These qualities give his works a strong resemblance to those of Molière, with whom critics have often compared him. He was elected to the Académie Goncourt in 1926. He died in Paris, June 25, 1929.

See Béatrice Elliott, *Georges Courteline* (1928); Albert Dubeux, *La Curieuse Vie de Georges Courteline* (1958). (A. Dx.)

**COURTENAY**, the name of a famous English family, earls of Devon. French genealogists head the pedigree of this line with one **ATHON**, who was lord of Courtenay in Gâtinais in about 1010. **ELIZABETH DE COURTENAY**, who in about 1150 married **Peter** (d. 1183), youngest brother of the French king Louis VII, was the heiress of Athon's great-grandson **RENAUD**. Their son **PETER** (d. 1219) was the founder of a short-lived dynasty of Latin emperors which ruled at Constantinople until 1261, and among their descendants were the lords of Champignolles, Tanlai, Yerre, Bleneau, La Ferté Loupière and Chevillon. **ROGER DE COURTENAY** (d. 1733), *abbé* of Eschalis, was the last recognized member of this royal line. **JOSCELIN I** (d. 1131), count of Edessa, was a grandson of Athon de Courtenay and a notable crusader; his son **JOSCELIN II** (d. 1159) ruled the county until 1150.

In England a house of Courtenay flourished with varying fortunes from 1161, when Henry II gave lands at Sutton, Berkshire, to its founder, **REYNOLD DE COURTENAY**. One of his sons, **REYNOLD**, married in about 1178 Hawise d'Aincourt, heiress of the old, married in about 1178 Hawise d'Aincourt, heiress of the honour of Oakhampton, Devon, and their son **ROBERT** (d. 1242) married Mary de Redvers, daughter of William (d. 1217), earl of Devon. From that marriage the Courtenays derived their later claim to the earldom of Devon and in 1293 Robert's great-grandson **HUGH DE COURTENAY** (d. 1340) inherited part of the estates of his distant cousin Isabel de Forz, countess of Devon and Aumale. Hugh was summoned to parliament as a baron from 1299 and he was recognized in 1335 as earl of Devon. The marriage in 1325 of his heir, **HUGH** (d. 1377), with Margaret de Bohun (d. 1391),

a granddaughter of Edward I and Queen Eleanor, gave later generations of their line the distinction of descent from the royal houses of England and Castile. However the Courtenays were an unlucky family and their earldom was one of the poorest in late medieval England. The eldest son of Earl Hugh II, Sir **HUGH DE COURTENAY**, died young in 1349; he had served at the battle of Crécy and at the siege of Calais and was one of the foundation members of the Order of the Garter. Earl Hugh was succeeded in 1377 by **EDWARD** (d. 1419), the son of his third son, Edward. Earl Edward is reputed to have become blind and took little part in public life. The 4th Courtenay earl of Devon was his second son, **HUGH** (d. 1422). In the Wars of the Roses Hugh's son **THOMAS** (d. 1458), earl of Devon, and his sons supported Henry VI, but they were at first chiefly concerned with pursuing a private feud with William, Lord Bonville (d. 1461), and the outrages committed in the west country by the earl of Devon and his men did much to discredit the Lancastrian cause and led the commons to petition in parliament in Nov. 1455 that Richard, duke of York, should be made lord protector. **THOMAS**, the 6th Courtenay earl, was captured by the Yorkists at the battle of Towton and beheaded at York on April 3, 1461. The earldom was granted by Edward IV in May 1469 to Sir Humphrey Stafford, who was executed during Robin of Redesdale's rising three months later. The main line of the Courtenay family was extinguished on May 4, 1471, when Earl Thomas' surviving brother, **JOHN**, who had been restored to the earldom during the brief return to power of Henry VI, was killed in the battle of Tewkesbury.

Sir **EDWARD COURTENAY** of Boconnock (d. 1509), whose grandfather had been a younger brother of Earl Edward, was created earl of Devon in Oct. 1485. Courtenay and his kinsman Peter, bishop of Exeter (afterward bishop of Winchester), had supported the rebellion of Henry Stafford, duke of Buckingham, against Richard III in 1483; after the failure of the rising they fled to France and were later attainted (1484). Sir Edward returned to England to fight for Henry Tudor at the battle of Bosworth Field in 1485 and the revival of the Devon earldom was his reward. He resolutely defended Exeter against Perkin Warbeck's rebels in Sept. 1497. His heir, **WILLIAM COURTENAY** (d. 1511), had married in 1495 Catherine (d. 1527), a sister of Henry VII's queen Elizabeth and a daughter of Edward IV. After Queen Elizabeth's death in 1503, William Courtenay was imprisoned on a charge of corresponding with the Yorkist exile Edmund de la Pole, earl of Suffolk, and he was attainted in Feb. 1504. On his accession in 1509, Henry VIII released his uncle, whose attainder was later reversed, and a month before his death in June 1511, Courtenay was made earl of Devon, the title having lapsed at his father's death. His son **HENRY** (d. 1539) was also treated with favour in the early years of Henry VIII's reign and in 1525 was created marquess of Exeter. Later his royal descent and opposition to the religious changes led to his destruction. He became involved in correspondence with the exiled Reginald Cardinal Pole, was sent to the Tower of London with his wife and son and was beheaded as a traitor in Jan. 1539. His son **EDWARD** (d. 1556) was released by Queen Mary in 1553 and created earl of Devon; he was soon regarded as a possible consort for the queen by those councilors who opposed her plans for the Spanish marriage. Courtenay was a foolish man who ill repaid the queen's kindness to him. Fortunately to escape with his life after being implicated in Sir Thomas Wyatt's rebellion in Feb. 1554, he was again imprisoned, was exiled at Easter 1555 and died at Padua, Italy, on Sept. 18, 1556. His heir male was a distant cousin, Sir **WILLIAM COURTENAY** (d. 1557) of Powderham castle, whose descendant, another Sir **WILLIAM**, was created Viscount Courtenay in 1762, a few months before his death.

The earldom was revived in 1831 in favour of **WILLIAM** (d. 1835), 3rd and last Viscount Courtenay, who remained in exile in Paris until his death. His heir presumptive, **WILLIAM COURTENAY** (d. 1859), clerk of the parliament, succeeded in persuading the house of lords that the Devon earldom created in 1553 was still in existence, on the grounds that the terms of the remainder—to Edward Courtenay and his heirs male forever—did not limit the succession to the heirs male of the body of the grantee. There

was no precedent for reviving a peerage for collateral heirs male and Lord Brougham's influence was responsible for this decision. Hitherto the title had been regarded as extinct, and the Courtenays of Powderham had made no claim or protest when the earldom of Devon was bestowed in 1603 on Charles Blount (d. 1606), Lord Mountjoy, and in 1618 on Sir William Cavendish, whose house continued to include that title among the peerage honours of the dukes of Devonshire. The 17th earl of Devon, CHARLES CHRISTOPHER COURTENAY (1916– ), descended from William Courtenay, who succeeded to the title in 1835 by virtue of the house of lords decision of 1831.

**COURTENAY, WILLIAM** (c. 1342–1396), archbishop of Canterbury from 1381 to 1396, a resolute leader of the English church and a moderating influence in the political disputes of Richard II's reign, was the fourth son of Hugh Courtenay, earl of Devon, and a great-grandson of Edward I. He studied law at Stapledon hall, Oxford, and became chancellor of the university in 1367. He received prebends at Exeter, Wells and York, was consecrated bishop of Hereford (1370), translated to London (1375) and became archbishop of Canterbury (1381). Courtenay proved a careful and zealous pastor; he gave vigorous leadership in convocation, defended the lower clergy against both papal and royal taxation, visited his diocese (1382) and dared to rebuke the king (1385). While protesting against the second Statute of Provisors (1390) as a restraint upon apostolic power and ecclesiastical liberty, he did much himself to reduce traffic in benefices. He found it necessary to censure the works of John Wycliffe and to suppress Lollardy, obtaining from the king permission to imprison heretics (1382) and to seize heretical books (1388). These activities brought him into conflict with John of Gaunt, duke of Lancaster, who for some time protected Wycliffe. In secular politics Courtenay was trusted by various parties and often played the role of mediator. He was among the 11 commissioners chosen in 1386 to regulate the king's household, and by his tact persuaded the king to meet them in 1387. Courtenay died at Maidstone on July 31, 1396, and was buried in Canterbury cathedral.

**COURTHOPE, WILLIAM JOHN** (1842–1917), English literary critic whose six-volume *History of English Poetry* (1895–1910) is based on an idea of poetry as the expression of a nation's history and relates its development to the age in which it was written. Born at South Malling, Sussex, July 17, 1842, and educated at Harrow and Oxford, he entered the education office, becoming senior commissioner in 1892. His continuation of Whitwell Elwin's edition of Pope, which includes the *Life*, showed his scholarship and his preference for the classical tradition in literature, as did his life of Addison (1882). His own poetry reflects his love of the English countryside. He was professor of poetry at Oxford, 1895–1901. He retired from the civil service in 1907, and died near Whitlugh, Sussex, April 10, 1917.

**COURT LEET**, an English petty criminal court for the punishment of small offenses. The word leet, denoting respectively a territorial and a jurisdictional area, was used in the entries relating to East Anglia in Domesday Book and in the quo warranto proceedings of Edward I. In the 14th century its use spread throughout England, and the term "court leet" came to mean a court in which a private lord held to his own profit jurisdiction otherwise exercised at the sheriff's turn (see HUNDRED). It was essentially a royal court, its president being the delegate of the king.

The court leet met twice a year, usually at Easter and Michaelmas, under the presidency of the lord's steward, who, by the end of the 13th century, was almost always a professional lawyer, and acted as judge. The court's two main functions were to hold

view of frankpledge (*q.v.*) and to receive the presentment of malefactors made by the juries constituted in the Assize of Clarendon (1166). This latter function became the more important although, as serious cases were increasingly reserved to itinerant justices, the rights of trial of small local courts became restricted to petty misdemeanour only and they normally only had cognizance of common-law offenses. From the 13th century onward lawyers tended to apply regulations concerning the sheriff's turn to the court leet: hence originated the legal but historically inaccurate theory that the court leet had developed from the sheriff's turn. Sir Edward Coke, in the 17th century, held that a court leet could not imprison; it could fine or amerce, but as time went on its capacity to enforce its judgments became progressively weaker. After the 16th century the duties of courts leet were increasingly transferred to the justices of the peace. Lords retained the courts, however, for the sake of the profits; some boroughs, such as Norwich and Southampton, continued to use them in local government. But the importance of the courts declined steadily although the Sheriff's act, 1887 (s. 40), expressly kept them up and they were not totally extinct in 1960.

See F. J. C. Hearnshaw, *Leet Jurisdiction in England* (1905).

**COURTLY LOVE**, the name given to a species of romantic love in which the relationship between lover and lady most nearly approximated to that of vassal and lord in the medieval feudal contract. It made its first appearance in the elaborate court poetry of the southern French troubadours (*q.v.*) at the end of the 11th century, and, once established in European tradition, its influence was profound and widespread. Minor lyric and romance were affected, as well as the work of major medieval authors such as Dante (1265–1321), Petrarch (1304–74) and Chaucer (1340–1400). It constituted a revolution of thought and feeling, the results of which are still apparent.

The character of the love celebrated by early troubadour poets is dramatic in the extreme. The lover is always in a position of servitude; he must obey his lady's wishes, however capricious or unjust they may be. But it is his privilege, not his misfortune, to exist subject to her, for love, whether rewarded or not, is regarded as the source of all true virtue and nobility. Within marriage, such love is held to be impossible; the lover habitually addresses the wife of another, and secrecy is therefore one of the important conditions of any favour granted to him. The ritual which surrounded the whole situation was observed reverently and devotedly; as later developments make even clearer, the courtly lover often thought of himself in a semireligious context, serving the all-powerful god of love and worshipping his lady-saint.

Classical and Nordic cultures provide no precedent for such an exotic philosophy of love. Latin and Greek poetry had dealt with erotic adventure with varying degrees of cynicism and tenderness, with domestic happiness, and, in a few striking cases, with love as a ruinous passion which, far from ennobling, destroyed nobility (e.g., the legends of Phaedra, Medea and Dido). Germanic and Celtic society showed itself even less favourable to the development of a romantic attitude to women; this was a world in which the most strongly valued human ties were those of lord and retainer.

**Social and Literary Influences.**—The circumstances which created the new sentiment, and made it an active force in late 11th-century France, are very various. Certain factors in its make-up are easily definable. Feudalism, with its binding obligations of loyal service to a lord upon whom all fortune depended, provided the general background and even, perhaps, some of the poetic vocabulary—the troubadours spoke often of the adored lady as "my lord" ("*midons*"). It may also be true that the conditions of life in the castle civilization of southern France at this time were favourable to the development of courtly love. Rich but isolated centres of refinement and culture, the castles contained many men but few women; to the lady of the castle the knight and squire may have felt themselves feudally inferior. The adulterous basis of such love is understandable in the light of medieval marriage conventions, and the attitude of the church to marital passion. Marriage was usually a business contract, involving property and military power but little sentiment; no

woman had freedom either to choose her husband or to prevent the annulment of the marriage for political or dynastic reasons if, as often happened, it was not a success. The teaching of the church upon the relationship between husband and wife was ambiguous as far as passionate love was concerned; it could have done little to encourage the growth of romantic devotion. For these reasons the idealization of passion could not be based upon the marriage state; poets looked beyond it.

But certain specific literary influences were also at work. The first is the *Ars Amatoria* of the Roman poet Ovid (43 B.C.-A.D. 18), a textbook upon the arts of seduction which was well known in France in the early middle ages and provided advice for both men and women. Ovid treats love with an ironic reverence, the lover making exaggerated obeisance to the god Amor and to the lady's slightest whims in order to achieve the gratification of his desires. The *Ars Amatoria* refers to extramarital intrigues, and it is clear that the troubadours drew upon it. The Ovidian lover is the slave of passion; he is pale, trembles, is unable to sleep or eat, swoons and is even known to die of love. Ovid's attitude to love, however, is mock-reverent; his adoration of the lady is an assumed pose, calculated to win purely sensual rewards. He is, for instance, willing to recommend force as a legitimate method if pleading fails, and he becomes, by turn, the servant and the master of the situation, indulging, if he pleases, in more than one liaison at a time. Although his book undoubtedly provided some of the material for the idea of courtly love, it could not have accounted for the wholly serious, idealistic outlook of its first medieval exponents.

Various sorts of explanation have been sought for this outlook. One view is that increasing veneration of the Virgin Mary helped to place the lady of the French poets in such an exalted position. Another view sees the matter as a clear case of the influence of religious heresy. Provence, during the years in question, was certainly a breeding ground for strange heretical beliefs which were not completely rooted out until the Albigensian crusades of the 13th century (1209-29) and it has been suggested that the earliest troubadours were inspired to write not by love of a real woman but by the mystical doctrines of the Cathari (*q.v.*). Its adherents were strong in Provence, and can sometimes be localized in those very castles where troubadours lived.

A rival claim has been made for the origins of courtly love in Arabic mystical philosophy; even if this is judged controversial, it is highly likely that the literature of Muslim Spain had a direct influence upon southern French poets. A treatise, the *Tawq al-hamamaw* (Eng. trans. by A. R. Nykl, *The Dove's Neck Ring*, 1931), written in 1022 by the Andalusian religious philosopher Ibn Hazm (994-1064), contains in detail most of the ideas which recur in all medieval treatments of courtly love from the troubadours onward. The *Tawq*, which draws upon many earlier eastern textbooks of love, and ultimately upon Platonic philosophy, contrasts strongly with Ovid's manual in that it seeks to discover spiritual significance in passionate relationships. While never denying the joys of union, Ibn Hazm approaches his themes in a refined, idealizing way, stressing, for instance, that love "is a reunion of souls in the original sphere of their higher world" and that to love properly requires the virtues of magnanimity, continence, loyalty and courage. Features of his doctrine which ring familiarly after a reading of European courtly love literature are: the sovereignty of love, the conception of love as a delightful disease, the association of love with sleeplessness and lamentations, the necessity of secrecy and of faithful service, and the almost blasphemous nature of faithlessness.

Considerable evidence supports the idea that during the late 11th century and the 12th century troubadour poets such as Guilhem, count of Poitiers (William IX, duke of Aquitaine), Cercamon, Marcabru and Jaufré Rudel (*see* TROUBADOURS) imitated and adapted Hispano-Arabic poetry written to conform with these principles. Guilhem married Philippa, widow of the king of Aragon, in 1094, and it is very likely that among those she brought with her to Aquitaine were singers knowledgeable in the Arabic ways of making poetry. In spite of the opposition of Christian and Muslim in the crusade warfare of those times and later,

there is good reason to suppose that Frenchmen could and did learn philosophies, stanza forms and melodies from their enemies.

Courtly love must therefore be regarded as the complex product of a number of factors—social, religious, philosophical, erotic—operating upon the privileged culture of Aquitaine and Provence in the 11th and 12th centuries. The expression given to it by the troubadour poets was varied and intricate; the finest of them, from Guilhem (1071-1127) to the later Bernart de Ventadorn (*c.* 1150-95) and Arnaut Daniel (*fl.* *c.* 1180-1210) made their strong personalities felt through extravagant modes of sentiment and metre.

**The Tradition Developed.**—*In France.*—But courtly love was not long confined to Languedoc, and as it spread to the north of France, England, Germany, Spain and Italy, it both developed and was modified. By the mid-12th century its themes were certainly in the hands of northern French poets. One of the decisive influences in this transmission was Eleanor of Aquitaine (*c.* 1122-1204), granddaughter of the early troubadour duke of Aquitaine. Married first to Louis VII of France, and then to Henry II of England, she inspired some of the best poetry of Bernart de Ventadorn; at her courts in France and in England she was a patroness of the new love poetry. Her daughter, Marie, countess of Champagne (1164-98), encouraged the writing of the most famous courtly love romance of the later 12th century: the *Lancelot* of Chrétien de Troyes (*q.v.*; *fl.* 1170) and possibly also the important textbook on the subject by Andreas Capellanus (André le Chapelain; *q.v.*, *fl.* 1200), the *De Arte Honeste Amandi*. Chrétien tells us at the beginning of *Lancelot* that Marie supplied him with both the content and the method of approach for his poem. Exactly how revolutionary her commands were is easily shown by a comparison of Chrétien's earlier poem, *Erec*, with *Lancelot*. In *Erec* the older view of women predominates—the heroine is a model of wifely patience and submissiveness in the face of harsh and unprovoked trials. In *Lancelot* we have, in the first place, an adulterous situation. The heroine, Guinevere, dictates imperiously to Lancelot, who obeys her in every unreasonable demand. The absolute sovereignty of love is recognized, and Lancelot approaches his lady's bed with the solemn reverence of a worshiper at a shrine. Chrétien's importance, in the present context, is that he was, as far as is known, the first to graft the theory of courtly love on to the old, originally Celtic narratives of Arthurian legend. It was a successful graft; others followed suit not only in France but also in Germany and England. From then on, Arthurian stories, such as those of Lancelot and Guinevere and Tristan and Iseult, were framed as typical courtly love situations, with the appropriate sentiment.

The contribution of Andreas Capellanus, writing late in the 12th century, was a textbook codification of the whole doctrine of courtly love, much on the lines of Ibn Hazm's *Tawq*. It consists of three books, two of which are devoted to such matters as the nature of love, methods of acquiring, retaining and increasing love, the signs of love and procedure to be followed in the event of one lover proving unfaithful. The initial definition given by Andreas could have come from the *Tawq*: "love is a certain inborn suffering." He stresses that love develops nobility, but also that it is the prerogative of the leisured and cultured classes. It would be inappropriate for a man to apply the rules of courtly love if he had the misfortune to fall enamoured of a peasant woman. In his specimen dialogues for lovers and his list of precepts, Andreas sums up the theory of courtly love as the high middle ages understood it. The impossibility of love between husband and wife is still maintained. Devotion to the lady's wishes and attention to secrecy are essential; the true lover is still subject to sleeplessness and violent agitation and is commonly pale through the "inborn suffering" he endures.

The fact that Andreas thought it wise to shape the third book of the treatise as a solemn exhortation to engage in the service of a higher love—that of God—should not lead us to doubt either the serious intent of the preceding books or their influence. Such palinodes are not uncommon in an age which was encouraged to see human affairs *sub specie aeternitatis* as well as from the viewpoint of the participant. Courtly love continued to enlarge its

dominions, sometimes retaining its original character, sometimes changing as it came into contact with new traditions of thought and literary forms. The long French allegorical poem of the 13th century, the *Roman de la Rose* (begun in 1237 by Guillaume de Lorris and finished before 1280 by Jean de Meun), took as its theme the story of the difficult progress of the courtly lover toward his goal, expressing it as a dream adventure within a walled garden; the lady's love is represented as a rosebud, enclosed by a thick thorn hedge. The dreamer, wounded mortally by the arrows of the god of love, becomes love's vassal and is instructed in his new duties with the familiar detail of the *De arte*. The rest of the Guillaume de Lorris section of the poem is taken up with the dreamer's triumphs and setbacks as he attempts to gain the lady's favour; he is in continual suspense, moving between happiness and despair in the way the middle ages had come to think natural to the lover's condition.

*In Italy and England.*—The 13th and 14th centuries saw courtly love pervading European literature; the romances and minnesinger lyrics of Germany are witnesses to its power, as are also the vernacular songs of Italy and England. But it is in the two last mentioned countries that it receives most interesting handling from great writers. Traditional contacts and exchanges had helped to make troubadour forms and doctrines well known to Italian poets, and as early as the 12th century their love poetry was imbued with courtly ideals. The essence of all the romantic material considered so far can be found in the lyrical and rhetorical verse addressed to Laura by Petrarch in the 14th century. More important still is Dante's fusion of courtly love and mystical vision. Beatrice is the idealized lady of his earthly devotion, who was, in fact, the wife of another. But she is also, in the *Divina Commedia* (1307?–21), wisdom, philosophy and spiritual guide to the mysteries of paradise.

English vernacular tradition had shown itself at home with many of the tenets of courtly love by the early 13th century. There are lyrics of this time which describe the blissful torments of the lover and the surpassing beauty of his imperious mistress. The extreme adulterous form of the convention, however, is not often represented. Courtly love was certainly a vital influential force upon medieval English literature, as can be proved by secular lyrics and romances, and also by religious prose treatises such as the *Ancrene Riwe* (c. 1180–1200) which portray Christ allegorically as the adoring suitor, petitioning his disdainful lady, the human soul. But it was adopted, on the whole, as a ritual of courtship rather than as an infinitely preferred alternative to, or compensation for, marriage. In one work, the late 14th-century romance, *Sir Gawain and the Green Knight*, the author goes so far as to have his hero reject the opportunity of a liaison with another man's wife because of his moral scruples. Sir Thomas Malory, in his great Arthurian compilation of the later 15th century, the *Morte d'Arthur*, does not change the outlines of the major courtly love narratives handed down to him from the 12th and 13th centuries, but reshapes, on occasion, a minor episode of this type to bring it more into harmony with an age which had begun to idealize marriage itself.

It is in the poetry of Chaucer, above all, that the most interesting developments of courtly love can be seen. Beginning his career with a translation of part of the *Roman de la Rose*, he adapts many of its elaborate procedures for the love situations of his minor poems. His first major work, *Troilus and Criseyde*, takes a story which is, in essentials, of the courtly mould, dealing with a secret love outside marriage and the consequent sufferings and transports of the lovers. But Chaucer's conception of this love is richly ambiguous. The union of Troilus and Criseyde, in the central part of the poem, is set against a background of pagan and Christian mythology; the dominant impression left with the reader is of sanctioned, not illicit, happiness. In spite of the bitter ending of the story—Criseyde unfaithful and Troilus dead—it is quite true to say that Chaucer has here "brought the old romance of adultery to the very frontiers of the modern . . . romance of marriage" (*The Allegory of Love*, by C. S. Lewis, Oxford University Press, rev. ed., 1951). Significant also is the fact that one of the later *Canterbury Tales*, that told by the Frank-

lin, describes a relationship between man and wife which possesses all the most valuable elements of the courtly code while lacking its obvious social and domestic disadvantages.

*Its Continued Influence.*—The history of courtly love after the medieval period is part of the general history of European sentiment, and as such cannot be treated without reference to innumerable religious and philosophical issues and literary fashions. Sixteenth-century English poets, in their enthusiasm for Italian verse, and for that of Petrarch in particular, reinterpreted the old extravagant attitudes and phrases for the Elizabethan age; the haughty lady of their lyrics is descended, ultimately, from the lady of the troubadour songs. In the poetry of Spenser (1552–99) on the other hand, we see the continuance of the process already begun in the 14th century; i.e., the absorption of courtly love into an ideal of marriage. It is this aspect of its development which has proved courtly love of greatest importance to western culture, although the imaginative appeal of the original stories of secret, unlimited passion has never failed to draw poets and musicians, and belief in the eccentric behaviour of the lover is a commonplace of popular tradition today.

**COURT-MARTIAL**, a court for the trial of offenses against military, naval or air force discipline, or for the administration of martial law.

**United States.**—The extraordinary jurisdiction of courts-martial is conferred by the constitution, which makes the president commander in chief of the armed forces and empowers congress to make rules for the government and regulation of the land and naval forces. It also exempts from the requirement for presentment or indictment by a grand jury "cases arising in the land or naval forces, or in the militia, when in actual service in time of war or public danger." Courts-martial are not part of the federal judiciary but are a part of the executive branch of the government. The proceedings and sentences of courts-martial, acting within their judicial powers and in accordance with law, are generally free from control or revision by the civil courts.

The jurisdiction of U.S. courts-martial is wholly penal or disciplinary. The specific objective of the courts is to ensure discipline in the armed forces. The jurisdiction embraces members of the armed forces and in certain cases civilians closely connected with these services (such as wives and other dependents and retainers to the camp outside the territorial jurisdiction of the United States) or interfering with their operation (such as spies). With regard to most offenses, jurisdiction is not limited by the place of the offense or by the locality of the offender. The members of a court function generally both as judge and jury. As a jury they sift and determine the facts in a case. Where there is a law officer he is primarily responsible for the determination of legal questions, such as admission of evidence, etc. Where there is no law officer (as in special courts-martial) the court itself determines all of these questions speaking through the president or senior member of the court. When a conviction has been reached, the members collectively function as a judge in determining the proper sentence within limits prescribed by law and regulations.

Otherwise, courts-martial processes are patterned after civil tribunals, and are designed to safeguard fundamental procedural and substantive rights of accused persons. Among others, these include the right to a thorough and impartial investigation before trial; to a speedy trial by an unbiased court; to protection from double jeopardy, compulsory self-incrimination and unreasonable searches and seizures; to the same presumption of innocence as in

federal courts; to the opportunity to be informed of the nature of the charges; to confront hostile witnesses; to the assistance of competent counsel, to be present in court throughout the trial, and to present whatever evidence there might be in defense or mitigation (including the right of compulsory process to obtain witnesses). Courts-martial are governed with respect to procedure and punishments by special enactments of congress. Until 1951 those applicable to the army and air force were called Articles of War, those applicable to the navy and coast guard, Articles for the Government of the Navy.

In 1950 the United States congress enacted a law to become effective May 31, 1951, called the Uniform Code of Military Justice, which consolidated and brought up to date the former statutes relating to the army, air force, navy and coast guard.

The Uniform Code of Military Justice retained many of the British enactments and regulations after which the first U.S. Articles of War were patterned when enacted in 1775. On June 4, 1920, the Articles of War were substantially amended and re-enacted. They were again amended and re-enacted June 24, 1948, incorporating improvements based upon experiences to date—particularly as a result of analysis of courts-martial during World War II. The Articles for the Government of the Navy, in effect Dec. 1, 1873, were codified as of that date as section 1624, revised statutes.

The Uniform Code of Military Justice provides three types of courts-martial—general, special and summary. General courts-martial are composed of not fewer than five members, plus a law officer, a trial counsel and a defense counsel, each with assistants (the law officer, trial counsel and defense counsel must be certified lawyers). General courts-martial have jurisdiction over any person subject to military law for any crime or offense made punishable by the Uniform Code and can impose any authorized punishment, including death, dismissal and dishonourable discharge. Special courts-martial are composed of not fewer than three members, a trial counsel and his assistants and a defense counsel and his assistants. Special courts-martial have jurisdiction over all persons subject to military law and over all offenses not punishable by death. They may not adjudge sentences to dishonourable separation from the service or to confinement in excess of six months, etc., but they may give a "bad conduct discharge." An accused enlisted man has the right to demand that at least one-third of the membership of the general or special court-martial which hears his case consist of enlisted persons from other than his own unit or organization. Summary courts-martial, consisting of one officer, are limited in jurisdiction to the trial of enlisted persons. Such courts-martial may not adjudge sentences in excess of confinement for one month, etc. Until May 31, 1951, the navy courts-martial were slightly different. The navy courts were termed general courts-martial, summary courts-martial and deck courts.

Courts-martial are of a transitory nature, called into being and dissolved by the commanding officer empowered by statute to appoint them. Such commanding officers are known as appointing or convening authorities. After trial the appointing authority or convening authorities and a sentence cannot be executed until it is approved and ordered executed by him, his successor in command or the commander for the time being.

Under the Uniform Code, all cases in which a punitive discharge has been approved by the convening authority will be reviewed by an appellate tribunal called a board of review, composed of three judge advocate officers or other legal specialists before the discharge may be executed. Any case in which the board of review sustains the punitive discharge, as well as certain other serious cases, may, under the Uniform Code, be appealed to the court of military appeals, composed of three civilian judges appointed by the president.

In all services death sentences must be finally acted upon by the president. Also in all services clemency powers are afforded by the articles and regulations, including the power to restore to honourable-duty status servicemen sentenced to punitive discharge. (See also MILITARY LAW.) (M. O. E.)

**Great Britain.**—The English courts-martial inherited part of the jurisdiction of the *curia militaris*, or court of chivalry. The

modern form was adopted by ordinance under Charles I and recognized by statute in the Mutiny act, 1689. This was superseded by the Army Discipline and Regulation act, 1879, and this in turn by the Army act, 1881, re-enacted annually by the Army (Annual) act, until 1955, when the Army act made a great constitutional change by dispensing with the need for an annual act. Part ii of this act deals with discipline, and sections 84-117 inclusive provide for courts-martial.

The salient feature of the court-martial, as contrasted with a civil court, is perhaps the position of the judge advocate. His main functions are to sum up the evidence and to direct the court, whose members are serving officers, on questions of law. When an accused officer or enlisted man is found guilty, the findings and sentence of the court are subject to confirmation or quashing by the commander in chief concerned, who is advised by a deputy judge advocate general, and ultimately by the secretary of state for war or air, as the case may be, who is advised by the judge advocate general of the forces. In accordance with a recommendation of the committee (1946-49) under Mr. Justice Lewis (Sir W. H. P. Lewis), the duty of advising on, and providing prosecuting officers for, the more important or difficult trials was taken away from the judge advocate general and transferred to legal departments of the war office and the air ministry.

Provision for martial law in its modern form dates for the navy as for the army from the reign of Charles I. The system rests on the Naval Discipline act, 1957, which repealed the previous act of 1866 and amending act of 1922 and, with the Army and Air Force acts of 1955, established a common code of discipline and of trial procedure for the three services. A naval court-martial may be ordered by the admiralty, or by an officer authorized by admiralty commission; it is composed of from five to nine officers (rank of lieutenant upward) with a president not below rank of captain. A judge advocate attends and the actual procedure is similar to that of an army or air force court, but the confirmation of the commander in chief or the admiralty is not required except for sentences of death; apart from capital cases, the board of admiralty has a general power of suspending, annulling and modifying sentences. All persons on board H.M. ships are subject to the Naval Discipline acts, including the Royal Marines, who are otherwise subject to the Army act.

In the Royal Air Force court-martial proceedings are governed by the principles laid down in the *Manual of Air Force Law* in compliance with the Air Force act, the Rules of Procedure and the Queen's regulations and are similar to those in the army.

Because courts-martial exercised very wide powers and were normally composed of persons with qualifications inferior to those of the high court, the absence of any provisions for appeals therefrom gave rise to increasing disquiet. To remedy this the Courts-Martial (Appeals) act, 1951, established a court broadly similar to the court of criminal appeal, except that there was to be no appeal against sentence. See also JUDGE ADVOCATE; MILITARY LAW. (W. T. Ws.)

**COURTNEY, LEONARD HENRY COURTNEY**, 1st BARON (1832-1918), British radical statesman and writer who gained wide recognition for his support of advanced radical causes, notably proportional representation, was born at Penzance on July 6, 1832, son of J. S. Courtney, a banker. Educated at St. John's college, Cambridge (he was second wrangler in the mathematical tripos), he was called to the bar in 1858, but worked as a journalist, becoming a leader writer on the *Times* in 1864. From 1872 to 1875 he was professor of political economy at University college, London. He stood unsuccessfully as member of parliament for Liskeard in 1874; he was elected two years later. He soon made his mark in the house of commons by his forthright

attack on the annexation of the Transvaal and vigorous support of women's suffrage and of the main concern of his career—proportional representation. In 1880 Gladstone appointed him under-secretary to the home office; in 1881 he was moved to the colonial office and in 1882 to the treasury, but he resigned in 1884 when he could not get proportional representation included in the redistribution bill. He did not support Gladstone on Home Rule for Ireland but was nevertheless made chairman of committees in 1886, filling the post with distinguished impartiality until 1892.

Courtney married in 1883 Kate Potter, Beatrice Webb's sister, and their home became a centre for the followers of John Stuart Mill, among whom he and his friend John Morley were pre-eminent. Courtney's strong opposition to the South African War lost him his seat in 1900, but neither his two failures to get re-elected nor his deteriorating eyesight interfered with his independent public work. He was made Baron Courtney of Penwith in 1906. During World War I he was as much out of step with the majority as in the South African War. Detesting militarism, he was an early advocate of a negotiated peace and a fearless defender of the conscientious objectors. He died in London on May 11, 1918. He wrote mainly for periodicals, but published two books, *The Working Constitution of the United Kingdom and Its Outgrowths* (1901) and *The Diary of a Churchgoer* (1904).

See G. P. Gooch, *Life of Lord Courtney* (1920). (M. A. H.)

**COURT OF APPEAL (BRITISH).** The court of appeal, one of the two major divisions of the supreme court of judicature, was created by the Judicature act, 1873. The master of the rolls is, in effect, its president. Its other permanent members are designated lords justices of appeal, but all high-court judges and holders or former holders of high judicial office are eligible to sit from time to time. It hears appeals from all three divisions of the high court and from the county courts, but not appeals in criminal matters, which are heard by the court of criminal appeal (see CRIMINAL APPEAL, COURT OF). It usually sits in three courts, and in most cases appeal lies to the house of lords by leave either of the court itself or of the house. See APPEAL: *Great Britain and the Commonwealth*; COURT: *England*; JUDICIARY AND COURT OFFICERS.

(W. T. Ws.)

**COURTOIS, JACQUES** (GIACOMO CORTESE) (1621–1676), French baroque painter, also called Le Bourguignon or Il Borgognone, was born at St. Hippolyte, near Besançon, in 1621. His father, whose pupil he became, was a painter. Toward 1640 he went to Bologna and studied under Guido Reni; then he proceeded to Rome, where he entered upon his own characteristic style of art, that of battle painting, in which he has been accounted to excel. Prince Matthias of Tuscany employed Courtois on some striking works in his villa, Lappoggio, representing the prince's military exploits. In Venice the artist also executed some battle pieces. In 1655 Courtois entered the Society of Jesus, and as a Jesuit painted many works in churches and monasteries of the society. He lived piously in Rome, and died there on Nov. 14, 1676.

His brother, GUILLAUME COURTOIS (1628–1679), was a painter and etcher, often assisting Jacques with his large compositions.

**COURTRAI** (Flem. KORTRIJK), the industrial capital of West Flanders, Belg., is situated on the Lys (Flem. *Leie*) and the Lys-Scheldt canal, 44 km. (27 mi.) S.W. of Ghent by road. Pop. (1961) 43,606.

In spite of damage by fire and in war, many old buildings of distinction remain as witnesses to medieval prosperity. The Broelbrug (c. 1400) is characteristic of medieval Flemish military architecture. The 16th-century town hall, a flamboyant piece of Gothic architecture (restored 1846), contains two elaborately carved chimney pieces. The church of Our Lady (begun 1191) was damaged by air raids in 1944. The chapel of the counts was attached to the church in 1374 and contains restored frescoes of the counts and countesses of Flanders, as well as an elaborate miniature, a 16th-century statue of St. Catherine. The church contains Sir Anthony Van Dyck's "Raising of the Cross" (1632). Railways run to, among other places, Brussels, Ghent, Lille and Ostend.

The population, one of the densest in Belgium, is employed making Courtrai linen and in the wood, wire and weaving industries.

The Roman Cortracum was established there. St. Eloi erected a chapel about 650 on the site of the present St. Martin's church, a 15th-century structure which was restored after destruction by fire in 1862. The town gained freedom with its first charter in 1190 and developed as a textile and trade centre which reached its peak in the middle ages. The Courtrai area is the largest producer and exporter of linen fibres in western Europe. In World War I Courtrai was in German hands from Oct. 1914 to Oct. 1918 and in World War II from May 1940 to Sept. 1944.

**Battle of Courtrai.**—In 1297 French troops invaded the town as well as most of Flanders. On July 11, 1302, Courtrai entered medieval history as the site of the "battle of the Spurs," which resulted from the action of the French king in imprisoning and confiscating the estates of Guy of Dampierre, count of Flanders. His subjects rose in revolt, but as they could raise only a small proportion of knights, their army appeared easy to crush by the powerful French army under Robert of Artois sent against them. The Flemish army took up a position with the Groeninghebeke covering the front, the Lys guarding the left flank and marshy ground on the right. With Courtrai in the rear, the Flemings had no hope of retreat.

The French first line of cavalry made a frontal attack after a duel across the stream between the rival crossbowmen. The passage through their own crossbowmen, the stream and up the slope beyond, threw them into confusion and the heavy mass of Flemish pikemen drove them backward. Robert of Artois strove to check them by throwing in his second line, which was easily crushed. The Flemings gave no quarter and Robert of Artois himself was among the slain, with 63 nobles and 700 knights. The intact French third line and foot then fled. After the battle about 700 pairs of golden metal spurs collected on the field were hung in a church (later demolished) as a thank offering. In 1382 Charles avenged the French defeat by sacking the town. (R. M. An.)

**COURT REPORTING**, the recording of the course of proceedings in an open court of law. The reports may be verbatim, as in the United States, or selective and edited, as in Great Britain and most European countries. The process used is customarily the taking of shorthand notes by a reporter, although in some courts various mechanical devices are being utilized.

The demand for the right to report trials and legislative proceedings developed in the 18th century with the spread of democratic ideals. However, until recently, the burden of making all arrangements and paying for reporting proceedings was borne by interested parties. In the United States today, most state courts and all U.S. district courts are provided with official reporters, paid by the government, who keep verbatim records of all trials. The expense of obtaining transcripts for an appeal is still borne by the interested parties, except that the government pays in the case of indigents. Provision has been made in Great Britain for official shorthand notes to be taken of all oral evidence and judgments in witness actions in the high court and in criminal cases at the assizes and quarter sessions throughout the country. Official shorthand notes are also taken of the judgments in superior appellate courts, such as the house of lords, the court of appeal, the court of criminal appeal and the divisional court, and the original notes are retained for at least ten years. They are not transcribed unless copies are ordered by interested parties wishing to buy them. In Great Britain the term "reporter" denotes not the shorthand writer but a barrister-at-law whose function it is to decide what decisions or points of law are "reportable," that is, suitable for inclusion in the *Law Reports*; and from a transcript of the shorthand note of the judgment and his own notes of the argument he prepares a report. (See LAW REPORTS.)

Although daily transcripts in U.S. courts are an important aid to the lawyer during a trial and to the judge in a nonjury case, the primary impact of court reporting is on U.S. appellate procedure, and it has contributed to making the appellate process a cornerstone of the U.S. legal system. When a case is taken from the trial court to a court of appeals, the trial record as prepared by the court reporter is the most important evidence available upon which the appellate court can base its decision. The insistence upon verbatim reporting is to ensure that the record will be

free from prejudicial omissions so that the appellate court can adequately determine whether the rights of all parties were observed during the trial. In this way, the court reporter's transcript is a guard against arbitrary judicial power just as the judiciary serves as a check on the possible exercise of arbitrary legislative and executive power.

The basic function of a court reporter is to attend and record such court sessions or other proceedings as are specified by statute or rule, or order of the court. In the United States the reporter is required by statute to record all that is said during the trial, including remarks of the parties and counsel out of hearing of the general public and jury. In cases other than criminal cases verbatim reporting may be dispensed with, but only upon the agreement of both parties and the sitting judge. Most reporters also record observations of expressions, tones of voices, threatening motions, etc., which occur during the trial. The reporter is free to interrupt the proceedings at any point to clarify a statement or spelling. In addition the judge may request the reporter to read from his notes at any time during the process of the trial.

In U.S. courts the reporter is considered an independent court officer, whereas in Great Britain his summaries are subject to the approval of the judge. The U.S. court reporter takes an oath to perform faithfully the duties of his office, and the records and transcripts to which he attaches his official certificate are considered *prima facie* correct when employed by the appellate tribunal. All original shorthand notes are filed with the clerk of the court and retained as records for at least ten years.

Although brief, rapid systems of writing to record the spoken word were developed by the Greeks and Romans and have been known throughout history, English court reporting came into its own with the development of the Pitman and Gregg shorthand systems in the 19th century. Court reporting in shorthand has become a highly skilled profession, and the reporter must possess great stenographic skill as well as quick perception and response. Handwritten shorthand systems remain the basis for court reporting today, although various mechanical methods for recording are also utilized by the reporter. These include stenotype or stenograph machines which have keyboards resembling those of typewriters and which produce a printed version of shorthand. The stenomask method by which the reporter repeats into a sound-recording device all words spoken during the trial is used extensively in military courts and adjudicatory proceedings of many state and federal agencies. In some courts sound-recording machines employing discs, wires or tapes are used, and their use is increasing with the development of more sensitive, high-fidelity recording equipment.

**COURTSHIP, ANIMAL.** When we see a peacock spreading his beautiful train to the full, and, occasionally vibrating the quills to produce a rustling sound, turning from side to side before his mate, or a barn-door cock with drooped wing and special call circling close round a hen, we are witnessing familiar examples of animal courtship.

Courtship may be defined to include all forms of action executed by members of one sex to stimulate members of the other sex to sexual activity. Such actions include the display of bright colours, or adornments such as crests; special tactile contacts; dances or other antics; pursuit; music, vocal or instrumental; the discharge of scents and perfumes; and the presentation of prey or of inedible but otherwise stimulating objects.

It is unfortunate that "courtship" is the only term available to denote these activities, since in our own species courtship is usually taken to mean only such activities as occur before marriage, in other words those that conduce to the finding of a more or less permanent mate. In most animals, however, marriage (in

the sense of the living together of one or more males with one or more females in sexual association for considerable periods of time) does not exist, and in many birds courtship displays do not begin until after the selection of mates has taken place. Courtship, in the biological sense, primarily leads up to the sex act; where some form of marriage exists, courtship may also, or even primarily, be connected with the choice of mates.

By no means do all organisms show even the most primitive form of courtship. It is not present in plants, or in any of the lower groups of animals. A few instances of rudimentary courtship occur in annelid worms, but otherwise it is confined to the vertebrates, the mollusks and the arthropods. Even here it is absent from many of the lower subdivisions of these groups. This becomes intelligible when the function of courtship is more closely looked into. No organism without a nervous system and sense organs can be expected to show courtship. In other forms, the union of the sexual cells is either entirely a matter of chance; or of simultaneous ripening and discharge (as when all sea urchins over a wide area discharge eggs and sperm at one time); or of passive transference, as in flower pollination; or of purely reflex reactions. Courtship will be needed only where the active co-operation of the sexes is needed for fertilization to be effected; and this will be the case only where the eggs and sperms are not blindly discharged, but are economized, either by means of internal fertilization or by being discharged in close proximity. Further, courtship will not be required where the nervous organization is so simple that pairing is a simple reflex action but only when the reflex machinery of pairing is under the control of higher centres in the brain, and the nerve processes of these centres and their emotional accompaniments need to be stimulated in a particular way before pairing can occur.

## INVERTEBRATES

**Annelids and Mollusks.**—The most primitive type of action that can be called courtship is found in certain marine annelids (bristle worms) related to the common sandworm *Nereis*. At the breeding season these annelids gather together and the males indulge in extraordinary contortions. These actions, whether by sight, touch or smell, appear to stimulate the females to shed their eggs, upon which the males discharge their sperm. Certain land snails are among the few mollusks that show courtship; and this in spite of the fact that they are hermaphroditic. They possess a structure called the dart, or *spiculum amoris*, secreted by a special sac. This is discharged with some violence during the preliminaries of mating and appears to stimulate the other animal, whose skin it may pierce. It might be expected that the highly organized cephalopods would have a striking courtship, but in spite of their peculiar method of fertilization, the meagre reports available do not bear this out (see CEPHALOPODA).

**Crustaceans.**—Although almost all Crustacea have well-developed special sense organs and internal fertilization, pursuit and forcible capture is usually the only preliminary to mating. In the semiterrestrial fiddler crabs, however, the males have one enormously enlarged claw, often brilliantly coloured, and this is employed in a primitive form of courtship—not, as at first surmised, in fights between rival males or forcibly carrying off females. In the breeding season, if a mature female passes near a sexually eager male, he stands on tiptoe and brandishes his claw in the air. The brandishing of the male's claw is to the female the visible symbol of the reproductive situation.

**Arachnids.**—A similar proclamation of a "sexual situation" appears also to be the main function of the courtship of male spiders. This, in certain of the hunting spiders (e.g., Lycosidae, Attidae), which possess good vision, consists in dances or contortions in which brightly coloured parts are prominently displayed. Web-spinning spiders, however, have poor vision; accordingly in some of them the courting male vibrates a strand of the web in a peculiar way. The importance to the males and to the race of inducing a sexual reaction in the female is here very great, since the female's normal reaction to any small animal would be to attack and devour it. The female does actually sometimes attempt to seize the male as prey, but gradually desists

as the courtship proceeds. The male spiders are occasionally devoured after fertilization. This appears to be the rule in scorpions, in which courtship takes the form of a dance with interlocked claws.

**Insects.**—In insects courtship is not infrequent. In many flies (e.g., *Drosophila*; *q.v.*) the male vibrates his wings in a special way. Some male butterflies, including the blues (*Lycaenidae*), have scent scales on their wings. The most remarkable of scent-producing courtships is that of *Hepialus*. Here the last pair of legs are transformed into organs rather like a powder puff, normally kept inserted in a pair of pouches lined with scent-producing glands. In courtship these organs are used to throw scent toward the female. The sound-producing organs of grasshoppers and crickets (interesting because they probably produced the first not merely accidental and functionless sounds in the history of life) serve mainly to bring the sexes together; but they doubtless also help to generate a sexual situation. The male of the tree cricket *Oecanthus* has a unique structure on his back, consisting of a gland capable of secreting a sweet liquid; during courtship he offers this secretion to the female.

Special food of a protein nature is needed by many female insects if their eggs are to undergo their final ripening. Accordingly a number of male insects present animal prey to the females as a part of courtship. In this way, two birds are killed with one biological stone. In some species of little flies of the family Empididae, the proffered prey is embedded in a "balloon" of glistening bubbles secreted by the male, and usually larger than himself, which renders him and his gift very conspicuous. In other species a strange modification of this habit has taken place. The balloon is still made and carried, but in place of the prey, bright objects such as flower petals and bits of coloured paper are placed in it. This utilization of foreign objects in courtship is paralleled elsewhere only by the bowerbirds and man.

#### VERTEBRATES

**Fishes.**—In vertebrates no courtship appears to exist in cyclostomes nor in the majority of fishes. Definite courtship, with striking adornments displayed by the males, is found only in a few fish species with internal fertilization or with peculiar breeding habits. In the cyprinodonts (top minnows and cave fish) fertilization is internal; and here the males are often brightly coloured and armed with special prolongations of ventral fin or tail; e.g., in the swordtail (*Xiphophorus*) the handsome breeding males swim excitedly round the females, occasionally giving them a dig with their long tail.

In the sticklebacks there are violent combats between males for the possession of nesting territory, but it is not certain whether display of the bright colours assumed by breeding males has any sexually stimulating effect on the females.

**Amphibians.**—In Amphibia the most specialized group, frogs and toads, has no display courtship, since the males' habit of embracing the females and waiting thus until the eggs are shed, when they discharge their sperm, renders it unnecessary. However, the meeting of the sexes is facilitated by the croaking of the males, which is often very loud owing to the development of huge vocal sacs. Here again possibly, though by no means certainly, the croaking has also a sexually stimulating function. If the chirping of male grasshopperlike insects was the first deliberate sound produced by life, the croaking of male froglike Amphibia was almost certainly life's first vocal music.

In the urodeles, or tailed amphibians, fertilization is internal, and here courtship is not infrequent. It usually consists in the male's rubbing himself against the female, at the same time discharging the secretion of special scent glands. It reaches its highest pitch in the European newts—*Triturus* and related genera—where the breeding males are usually brightly coloured and dance round the females in striking postures while fanning scent from special glands upon them with their tails. The sexually stimulating function of this performance is here very definite. The males of these genera deposit their sperm in a packet, or spermatophore, and this must be actually picked up by the female for fertilization to occur. Females are quite irrespon-

sive to the presence of isolated spermatophores, but will pick them up when stimulated by the male's performance.

**Reptiles.**—Of reptilian courtship comparatively little is known; its study, especially in the more active lizards and snakes, should certainly yield many interesting facts.

**Mammals.**—The two remaining vertebrate classes, birds and mammals, differ considerably in regard to courtship, its frequency and duration being much greater among birds, whereas it is commonly completely or almost completely absent in the case of mammals. When courtship does occur in mammals it is not infrequently associated with male combat. The biological reasons for the rarity of courtship in mammals appear to be the following: first, most female mammals, owing to their special method of nourishing their embryonic young, have their reproductive activity very strictly controlled by means of hormones. At certain definite periods the uterus is ready for the embryo's implantation and one or more ova are shed from the ovary; simultaneously, the sexual instincts are strongly stimulated, and the female will readily mate with almost any male, at the same time becoming an object of the males' strong sexual desire owing to an odour specially produced at this period. In other words, the sexual attractiveness of the female and still more her readiness to mate are in the main chemically controlled, the intensity of sexual emotion during the period of "heat" or oestrus being in general very high. In birds, on the other hand, although the sex hormones produced in the breeding female predispose her to sexual emotion, their activity is neither so limited in time nor so intense, while in addition the males are more helpless than in most groups to enforce their desires on an unwilling female. (*See REPRODUCTION: Physiology of Reproduction.*)

In most mammals, the cyclical production of female sex hormones thus automatically ensures mating. As a result, both definite courtship and secondary sexual adornments are rare. Since female preference counts for so little, the winning of females by battle will secure them as mates, and consequently size and strength, as of the elephant seal, offensive weapons like stags' antlers or stallions' canines, and defensive weapons like the lion's mane or the baboon's "cape" of long hair are the chief secondary male characters.

In monkeys and apes there appears the tendency, which reaches its climax in civilized man, of emancipating the female's sexual emotions from the strict cyclical control of hormones, and allowing them free play at other times than at oestrus. The mating season is extended over more of the year, and the animals become ready to pair at other periods of the menstrual cycle than oestrus. In such circumstances it would be expected that stimulation by courtship and display would once more become of biological importance, and in point of fact primates do show a number of striking sexual adornments, such as beards, mustaches or whiskers; bright coloured hair on the face; or brilliantly coloured patches of bare skin on the face and buttocks. In man, of course, courtship is highly developed and obviously plays an important biological role; but it cannot be discussed in a purely zoological article.

**Birds.**—It is in birds that courtship is most universal and striking, and its details and its biological significance have been here most thoroughly investigated. Consequently, certain general rules can be laid down as regards the form that courtship takes in birds of different modes of life and reproduction.

1. The racial function of the male bird may be confined to fertilization (ruff, black grouse); or he may also mount guard during the female's incubation (most ducks); or may also share in feeding the young (most perching birds and hawks); or also in incubation (grebes, herons, etc.). The more duties he executes for the good of the offspring, the greater is what may be called his racial value. To kill a male ruff immediately after fertilization has no deleterious effects on the next generation, whereas the death of a male grebe or heron at the same period seriously imperils the chances of the eggs and young.

2. The "marriage systems" of birds vary from permanent monogamy (parrots, ravens) through monogamy for one season (most monogamous birds) or one brood (some wrens) to poly-

any of the "small harem" type (jungle fowl, many pheasants) or of the promiscuous type (ruff, blackcock, probably some birds of paradise).

3. The need for protection by means of protective coloration and inconspicuous habits varies considerably. Birds that nest gregariously, in general, need less protection at the nest site than do birds nesting solitarily.

4. The need for a continuous supply of food to the naked young of most perching birds has resulted in the adoption by species of the system of "food territory" in which the male and later the pair defend from intruders an area of some extent round their nest. (See BIRD: *Breeding*.)

Courtship is modified in various ways with reference to these facts. In general, the less the share of the male in the care of eggs and young, the greater the difference between the sexes in plumage, and the more striking the (exclusively male) courtship behaviour. This is owing to the greater need for sober colouring and inconspicuous behaviour in the female, on whom the whole fate of the brood depends, and the lesser need in the male.

The greater the degree of polygamy, the greater in general the intensity of courtship and the exaggeration of display characters. This is due to the fact that with polygamy the successful males transmit their characters to many offsprings, while the less successful do not transmit their characters at all. Thus the premium on success in mating is greater. On the other hand, where the male plays a part closely similar to that of the female in incubation and care of the young, both sexes tend to be similar in plumage, and often both develop display characters (crest of crested grebe, plumes of herons).

Mutual courtship is often prolonged until the young are no longer under parental care (divers, egrets, grebes, albatrosses). In such cases it is probable that courtship, in addition to its function in raising the level of sexual emotion, has a secondary function as an emotional bond that helps to keep the pair together for the sake of the young.

Then, the greater the need for protection, the less will be the development of bright colours and display characters. In extreme cases, as in European warblers, the sexes are practically identical in coloration, although the male alone displays in courtship.

In solitary birds with concealed nests, it is rare for courtship to take place near the nest, for fear of revealing its site. When this danger is not of importance, courtship may occur at the nest (e.g., in the rook). It is especially noticeable in gregarious birds with mutual courtship (e.g., pelicans, herons): a joint ceremony is often performed when one bird relieves its mate on the nest.

Finally, where food territory exists, many sexual activities are related with the territorial system and not, as was originally thought, with true courtship. For instance, the song of all our common singing birds is mainly an advertisement to females of the presence of a male in possession of territory, and a warning notice to other males to keep out.

There is often a renewed activity of courtship in a mild form in early autumn when the birds are released from family cares and are still warm and well fed. In some gregarious forms this appears to blend with the remarkable social performances of this season (e.g., stone curlew). In the oyster catcher, the same performance is employed both in courtship and to demonstrate sexual or territorial jealousy. When these two motives reinforce each other, this performance may be joined in by a number of birds and assumes in a rudimentary way a social character, as of a human dance.

In courtship, grebes and divers present weeds to their mates; penguins, stones; herons, sticks; warblers, twigs or leaves. In all such cases the objects presented constitute nesting material; it appears that some association occurs between the two pleasurable breeding activities of nest building and courtship.

Occasionally nonsexual actions are incorporated in courtship. Grebes often give a useless (one might say "ritual") imitation of preening their wings during courtship, and swans behave somewhat similarly. The psychological explanation of this is not easy.

An interesting psychological transference has been noted in the

Adelie penguin. The males may present nesting material (stones) not only, as is normal, to the females as part of courtship but to other organisms that interest them, such as explorers and dogs.

Another type of transference has been observed in a captive male Argus pheasant. The courtship of this species is given to a stationary female. The female with which this male was confined belonged to another species and would not stand still. The male, after repeated attempts to display before the female, gave up and proceeded to display before his water trough.

Almost as a matter of course, the mode of life is reflected in courtship. As part of courtship, the males of the fast-flying falcons fly straight at their mates; the golden-eye drake raises a jet of water with his feet; grebes, divers, and various diving ducks use their diving powers to appear from below the surface in striking display poses close to their mates and so forth.

In some ways the most remarkable courtship known is that of the bowerbirds (*q.v.*). These birds clear playgrounds, in which special bowers (quite unlike nests) are constructed by some species. In the playground (if a bower is made opposite its entrance) is deposited a collection of bright objects. The objects differ with the species; they may include silvery leaves, flowers, shells, berries, bones, etc. When the female visits the playground, the male pursues her amorously round it (through the bower, when present). Here it appears that the bright objects collected serve instead of the brilliant plumage of other male birds to stimulate the female.

The details of courtship vary enormously from species to species. They all have in common two facts. First, the display presents the bird in an unusual aspect; and presumably stimulates by its very unusualness. Secondly, when bright colours or special plumage exist only in one sex, or only during the breeding season, these are in the great majority of cases made specially conspicuous in courtship. Often such characteristics are normally concealed, but made visible only by display.

A great deal still remains to be discovered about courtship, and amateur naturalists can render considerable service to biology by recording the results of intensive observation of the whole courtship period even of quite common species.

**COUSIN, VICTOR** (1792–1867), French philosopher, the exponent of systematic eclecticism, educational reformer and historian, was born in Paris on Nov. 28, 1792. At the age of 18 he passed from the Lycée Charlemagne to the École Normale. There, in 1811, he came under the influence of Pierre Laromiguière, who introduced him to the philosophy of Locke and the abbé de Condillac. This influence, however, was soon supplemented by that of P. P. Royer-Collard, the political leader of the Doctrinaires and the champion of Scottish philosophy; and by that of Maine de Biran. Furthermore, after an early period of teaching at the École Normale and, as Royer-Collard's assistant, at the faculty of letters in the university (1815–16), Cousin went to Germany to familiarize himself with contemporary philosophy there, meeting Hegel, Schelling and Jacobi (1817–18).

In the reaction against liberalism that followed the assassination of the duc de Berry, Cousin was deprived of his assistantship at the faculty of letters (1820); the École Normale was closed in 1822; and, on another visit to Germany, Cousin was arrested in Dresden on a political charge and held prisoner for about six months in Berlin (1824–25). In this period of official disgrace, however, he had the leisure not only to produce the important *Fragments philosophiques* of 1826 but also to complete editions of Proclus

(1820-23) and of Descartes (1824-26) and to begin his translation of Plato (1822-40). Reinstated at the university in 1828, he embarked on a series of lectures on philosophy that enjoyed an unprecedented popularity. His influence was enormous.

The principles of the July revolution (1830) coincided well enough with Cousin's political inclinations. He became a member of the council of public instruction (1830), of the Académie Française (1831) and of the revived Académie des Sciences Morales et Politiques (1832), a peer of France (1832), director of the École Normale (1834) and, in Adolphe Thiers' government, minister of public instruction (1840). Guizot's epoch-making reform of primary education (1833) was inspired by Cousin, who in 1831 went on a mission to Germany to study the system obtaining there (see his influential *Rapport sur l'état de l'instruction publique dans quelques pays de l'Allemagne et particulièrement en Prusse*, 1833; Eng. trans., London, 1834; U.S. digest, Albany, N.Y., 1836). It was Cousin who drafted the bill as presented by Guizot.

In the following years, apart from his new official duties, Cousin, no longer lecturing, found time for the revision of his past lectures, for the completion of work already begun and for new literary pursuits. This activity he continued during his retirement from public life after the fall of the July monarchy. His publications include *De la Métaphysique d'Aristote* (1835), *Cours de philosophie professé... pendant l'année 1818... sur le fondement des idées absolues du vrai, du beau et du bien* (1836; many subsequent editions); *Cours d'histoire de la philosophie morale au XVIII<sup>e</sup> siècle*, 4 vol. (1839-42); *Des Pensées de Pascal* (1843); *Leçons sur la philosophie de Kant* (1844); editions of Abelard (*Ouvrages inédits*, 1836, and *Opera*, 2 vol., 1849-59) and of Maine de Biran (1841); and a series of studies on 17th-century women, *Jacqueline Pascal* (1845), *Madame de Longueville* (1853), *Madame de Sablé* (1854) and *Madame de Chevreuse et Madame de Hautefort* (1856). Cousin died on Jan. 13, 1867, at Cannes.

His philosophy was based on the psychological observation and analysis of the facts of consciousness and on inferences made from the observed facts. This method was the unifying factor of his eclectic system. Consciousness he saw to comprise two necessary or impersonal elements, sensation and reason, and the contingent or personal and individual element of will (in which secondary or reflective volition must be distinguished from primary or spontaneous volition, the original liberty actuating all the processes of consciousness in the individual). Cousin's presentation of reason as a psychological fact, a component of consciousness independent of the will rather than a function of the mind, enabled him to evade the subjectivism of Kant; and on the principles of reason he claimed to establish the ontological reality of the two causally interdependent substances, the *me* and the *not-me*, the consciousness and the phenomenal world, which together, being correlative, must have God as an absolute and self-sufficient cause. His eclecticism was the application of his method to the history of philosophy: the several systems (sensualism, idealism, skepticism and mysticism) were facets of a total truth discernible in the composition of their positive aspects, this synthesis being a converse process to his analysis of consciousness.

**COUSIN MARRIAGE.** Whereas sex relations between man and his sister or half-sister are almost universally regarded as incestuous, the corresponding rules governing the relations between first cousins show extreme variation. There are societies which treat sex relations between a man and any female first cousin as incestuous and others which consider marriage between first cousins an ideal to be sought by all. Others again permit marriage between certain categories of first cousin only. There is no evidence that any of these different rules have any genetic consequence, and the common belief that the children of a first-cousin marriage are likely to be physically or mentally defective is only the reflection of a sentiment which associates such marriage with incest.

For purposes of technical discussion, anthropologists distin-

guish the different types of first cousin as follows: in relation to any Ego, cousins on the father's side are patrilineal, those on the mother's side matrilineal; the children of two sisters or of two brothers are ortho-cousins (parallel cousins); the children of a brother and a sister are cross-cousins. The diagram thus distinguishes four types of female first cousin in relation to the male Ego.

Whereas the English word "cousin" covers all four of these relationships, many languages place the ortho-cousins and the cross-cousins in separate categories; in such cases the terms used to denote the ortho-cousins are frequently the same as those denoting brothers and sisters. A smaller group of languages places the ortho-cousins in one category but distinguishes the patrilineal cross-cousins from the matrilineal cross-cousins. Still another group of languages contains separate terms for each of the four female cousins. Many languages make further category distinctions which depend upon whether the girl in question is older or younger than the male Ego (see KINSHIP TERMINOLOGY).

Such variations of kin-term classification correlate in an approximate, but far from absolute, way with variations in the rules relating to cousin marriage (see table). In the classification of G. P. Murdock (1949) the tabulated linguistic usages are typed as IA Hawaiian, IB Eskimo, II Iroquois, III (i) Crow, III (ii) Omaha, IV Sudanese. For details see KINSHIP TERMINOLOGY.

Linguistic usage	Typical associated marriage rule	Example	Rough distribution of this type of rule
IA A, B, C, D, all classed together as "sisters"	Marriage preference for kinswoman of own generation including any cousin but excluding true sisters	Iban	Indonesia Polynesia
IB A, B, C, D, all classed together but distinguished from sisters	Marriage with any first cousin tolerated but not preferred	English	Europe Arctic regions
II Ortho-cousins classed together as sisters but distinguished from cross-cousins who are classed together	Marriage with ortho-cousins forbidden Marriage with cross-cousins (i) forbidden (ii) tolerated (iii) strongly approved	(i) Aranda (ii) Sinhalese (iii) Kari- era	World-wide
III Ortho-cousins classed together as sisters but distinguished from cross-cousins who are classed separately, A by one term, D by another	Marriage with ortho-cousins forbidden Marriage with (i) A allowed but D forbidden (ii) D allowed but A forbidden	(i) Trobri- ands (ii) Kachin	World-wide
IV A, B, C, D, all distinguished by separate terms	Marriage with any first cousin approved, especially with B	Bedouin	North Africa Western Asia

While there is a certain rough correlation between the pattern of linguistic usage and the type of marriage rule, other fundamental elements in the total social structure of the society are relevant. Thus, irrespective of marriage rule, most societies which emphasize a principle of unilineal descent (matrilineal, patrilineal or both) also make the linguistic category distinction between ortho-cousin and cross-cousin. Again, in the table, terms of type III (i) are usually matrilineal while those of type III (ii) are usually patrilineal. But there are many exceptions to all such generalizations: e.g., the Tikopia (Polynesia) are patrilineal, class all first cousins as sisters and tolerate any form of first-cousin marriage; the Sinhalese distinguish ortho-cousins from cross-cousins, forbid marriage with the former, but do not have a system of unilineal descent. It is erroneous to think that mar-

riage rules can be directly inferred from a study of kinship terminologies.

Strong moral approval of first-cousin marriage does not necessarily imply a high incidence of such marriages. Thus B. Malinowski reported that the Trobrianders considered marriage with the father's sister's daughter to be ideal, but actual instances of such marriage among these people appear to be rare. On the other hand it was reported of a community of Kurds that nearly 60% of all marriages were of the preferred type—in this case with the father's brother's daughter. The literature on such matters is often misleading. Thus the Kachin were said to have a rule requiring marriage with the mother's brother's daughter, but in fact the rule requires marriage with a relative of the class *nam*, which includes a wide variety of women of whom the matrilineal cross-cousin is only one.

Special interest in cousin marriage first arose from attempts to establish an absolute correlation between marriage rules and systems of kinship terminology and from a belief that the varieties of marriage rule reported from different parts of the world represent an evolutionary series. L. H. Morgan supposed that the rules governing the marriage of near kin were critical markers of the stages of human social development, and modifications of this doctrine by later writers, notably W. H. R. Rivers, produced a mass of intricate *a priori* reasoning concerning the supposed origin of various marriage rules and kin-term systems. A. R. Radcliffe-Brown (1931) demonstrated that the exceedingly intricate systems of kinship terminology and marriage regulation among Australian Aborigines might result from a practice of sister-exchange marriage between closely related males. But the significance of any particular marriage rule in any particular society will depend upon the circumstances of that society, especially upon the associated customs regarding succession, inheritance and residence. As a consequence, following Malinowski, later anthropological work was more concerned with the implications of different types of marriage regulation under special local circumstances and much less with speculation about the historical origins of particular customs.

In the *Bibliography*, items dating from 1949 onward reflect this new approach. The arguments, often highly technical and hotly disputed, are concerned not only with the significance of particular configurations of custom but with why some patterns (e.g., III [ii]) occur much more frequently than other similar patterns (e.g., III [i]). In this group of writings the work of C. Lévi-Strauss deserves special attention.

**COUSINS, SAMUEL** (1801–1887), English mezzotint engraver, pre-eminently the interpreter of Sir Thomas Lawrence, was born at Exeter on May 9, 1801. During his apprenticeship to S. W. Reynolds he engraved many of the best among the 360 little mezzotints illustrating the works of Sir Joshua Reynolds. In the finest of his transcripts of Lawrence, such as "Master Lambton," his brilliancy and force of effect in a high key corresponded exactly with qualities of the painter. After the introduction of steel for engraving, about 1823, Cousins and his contemporaries were compelled to use it because the soft copper employed for mezzotint plates did not yield enough fine impressions for commercial competition with line engraving. Because of the hardness of steel, the painterlike quality of mezzotints of the 18th century was wanting in Cousins' later works. The labour of scraping was so

augmented that Cousins resorted to using stipple engraving and etching processes. To this mixed style, he added heavy roulette and rocking-tool textures. The effect of these prints was mechanical, but their phenomenal popularity kept alive a form of mezzotint during a critical phase of its history. Cousins died in London on May 7, 1887.

See Alfred Whitman, *Samuel Cousins* (1904).

(H. Es.)

**COUSTOU**, the name of a family of French sculptors.

NICOLAS COUSTOU (1658–1733), whose style continued the academic grand manner of the Versailles sculptors with some slight concession toward the freedom of the rococo, and his younger brother, GUILLAUME I (1677–1746), were born at Lyons. Both were brought to Paris by their uncle, Antoine Coysevox (*q.v.*), under whom they studied. After four years in Rome (1683–87), Nicolas was elected an academician (1693) and received a large number of commissions from the crown, particularly for garden sculpture at Versailles (Trianon) and above all at Marly, where he executed, among numerous other works, "Le Seine et le Marne" (1712). Among his religious works the most important was the "Descent From the Cross" (1725) for the high altar at Notre Dame. Guillaume I went to Rome in 1697 where he worked with Pierre Legros, whose extremely baroque style influenced him strongly. He became an academician in 1704 and was chiefly employed to provide garden sculpture for the various royal palaces, notably part of the "Compagnie de Diane" (1712–13) at Marly, but his most celebrated works were the "Chevaux de Marly" (1740–45) designed to replace Coysevox's horses which they now confront across the Place de la Concorde in Paris. His work for Parisian churches included the "Vow of Louis XIII" in the choir of Notre Dame (1713–15) and, in addition, he did some portrait sculpture. His work has a picturesque character and is closer to the rococo than his brother's, as emerges when Guillaume's "Marie Leszcinska en Junon" is compared with its pendant "Louis XV en Apollon" by Nicolas.

GUILLAUME II COUSTOU (1716–1777), son and pupil of Guillaume I, also provided much sculpture for the gardens of the royal palaces, for Mme de Pompadour, etc., but his style displays a further development of 18th-century taste. His later work, particularly his masterpiece, the tomb of the dauphin in Sens cathedral (1766–77, after designs by C. N. Cochin) is already neoclassical in feeling.

**COUTHON, GEORGES** (1755–1794), French revolutionary who was closely associated with Robespierre and Saint-Just during the period of the Terror, was born at Orcet, in Auvergne, on Dec. 22, 1755. Brought up in the house of an attorney at Riom, he became a poor people's advocate at Clermont-Ferrand, where he was appointed president of the tribunal in 1790. Elected a deputy to the Legislative Assembly (1791), he opposed La Fayette and spoke in the Jacobin club (over which he presided in November) in support of the "patriot" soldiers who rose against their officers. Having lost the use of his legs as the result of an illness, he had to be carried about on another man's back or in a wheel-chair. Elected to the Convention in 1792, he proposed the proclamation of the sovereignty of the people and voted for Louis XVI's death without reprieve. Despite his infirmity he was sent on missions to Loir-et-Cher in Nov.–Dec. 1792 and to the principality of Salm in March 1793. A bitter opponent of the "federal" movement, he procured the arrest of the Girondin deputies in their homes on June 2, 1793. He became a member of the committee of public safety on July 10 and was sent on Aug. 21 on a special mission to the army which was besieging Lyons. With the help of volunteers whom he raised in the Puy-de-Dôme he hastened the taking of the town, but he could not bring himself to carry out the decrees of the Convention ordering its destruction. Of a conciliatory nature, he loathed useless violence, but approved of energetic action against dissidents. An ardent patriot, he frequently intervened in the debates on the army and, on Dec. 21, 1793, was elected president of the Convention. Sharing

the egalitarian ideas of Robespierre and Saint-Just, he first, on Jan. 26, 1794, proposed the confiscation of the property of suspects and then, in February, approved the decrees envisaging the distribution of this property among poor citizens. He took an active part in bringing about the downfall of the Hébertists and of Danton and carried the famous law of 22 Prairial (June 10, 1794), which speeded up the work of the Revolutionary tribunal. During the crisis preceding the Thermidorian reaction he managed to stay in Paris (ignoring decrees which would have sent him away on special missions) and gave his full support to Robespierre. Arrested with him on 9 Thermidor (July 27, 1794), he was taken to the prison of La Bourbe. Set free during the night, he was with Robespierre at the Hôtel de Ville when they were seized as outlaws on the following morning. They were guillotined before the day was over (July 28, 1794).

Aulard, *L'Éloquence parlementaire pendant la Révolution: les Orateurs de la Législative et la Convention*, ii, 425–443 (1885–86). (M. A. B.)

**COUTTS, THOMAS** (1735–1822), English banker and founder of the banking house of Coutts & Co., was born on Sept. 7, 1735. He was the fourth son of John Coutts (1699–1751), lord provost of Edinburgh in 1742, who carried on a business in corn and negotiated bills of exchange. Soon after the death of John Coutts the business was divided into two branches, one carried on in Edinburgh, the other in London. The banking business in London was in the hands of James and Thomas Coutts, sons of John Coutts.

From the death of his brother in 1778, Thomas, as surviving partner, became sole head of the firm; and under his direction the banking house was firmly established. He died in London on Feb. 24, 1822.

See C. Rogers, *Genealogical Memoirs of the Families of Colt and Coutts* (1879); and R. Richardson, *Coutts & Co.* (1900).

**COUTURE, THOMAS** (1815–1879), French academic historical and genre painter, was born Dec. 21, 1815, at Senlis (Oise), and studied under Baron A. J. Gros and Paul Delaroche, winning a Prix de Rome in 1837. He was best known for his "Romans in the Decadence of the Empire" (1847) and his "Love of Money" (1844). Couture was very popular as a teacher; among his pupils were Manet, Puvis de Chavannes and the Americans William Morris Hunt and John La Farge. He died March 30, 1879, at Villiers-le-Bel, near Paris.

**COUVADE** (from the French *couver*, "to hatch") is the custom of the father going to bed at the birth of his child, complaining of labour pains, observing dietary restrictions or otherwise acting like a woman in confinement. In its extreme form, the mother returns to her work as soon as possible after giving birth, often the same day, and waits on the father; thus the roles of the sexes are reversed. The term is sometimes applied to examples where both parents of a newborn child are confined and restricted to about the same degree, and even to instances where the father is less restricted than the mother. However, because some restrictions on the behaviour of the father at the birth of a child are almost universal among primitive and ancient peoples, it is best to ignore minor tabus affecting the father and to label the confinement and major restrictions applied with about equal force to both parents the "half-couvade."

The full couvade was practised on the island of Corsica in the first century A.D., in later antiquity probably on Cyprus, and in Spain. It was reported in the 19th century on the Balearic Islands, among the Basque of the Pyrénées, in France, and as late as the early 20th century in the Baltic states and in Holland. In Africa, it has been reported for the Congo area in recent times. In Asia, it first appeared in Pontus, on the southern shore of the Black sea; in ancient times, was observed by Marco Polo in Chinese Turkistan; was found among the Maiotzu tribe of south China in the 18th century; and in the 19th century occurred among the Ainu of Japan and a number of peoples of India. In Oceania it was observed in the 19th century on the Nicobar Islands, the Moluccas and the Solomons. Among the North American Indians it occurred only among the California tribes, but was

present in the West Indies and among South American Indians east of the Andes as far south as Paraguay.

W. R. Dawson favoured the theory of a single origin of the custom in the eastern Mediterranean and its subsequent dispersal by migration or diffusion to all other localities where it has been reported. A more representative mid-20th century view is that the couvade originated independently a half dozen or so times in each major area of occurrence and subsequently spread to neighbouring peoples. Its social function is to emphasize the role of the father in reproduction, but those primitive societies which lacked the couvade were not ignorant of biological paternity, as some 19th century writers supposed.

**COVARRUBIAS, MIGUEL** (1904–1957), Mexican painter, writer and anthropologist, was born in Mexico City. He received little formal training. In 1923 he went to New York city on a government scholarship, and his incisive caricatures soon began to appear in *Vanity Fair* and elsewhere; a collection, *The Prince of Wales and Other Famous Americans*, was published in 1925. He illustrated numerous magazines and books, extending his interest to the study of racial types. In 1930 and 1933 he and his wife, a photographer, visited the orient, and subsequently he wrote *Island of Bali* (1937). In 1939 Covarrubias painted six mural maps illustrating the cultures of the Pacific area for the Golden Gate International exposition, San Francisco, published as *Pageant of the Pacific* (1940). Turning to Mexico, he wrote and illustrated an account of the Tehuantepec region, *Mexico South* (1946). His last book, *The Eagle, the Jaguar, and the Serpent* (1954), surveyed the cultures of the northern American Indians. Covarrubias also worked as a theatre designer, easel painter, print maker and teacher. His work reflects a flair for decoration, perceptiveness and thorough craftsmanship. He died at Mexico City on Feb. 4, 1957.

**COVELLITE**, a mineral species consisting of cupric sulfide ( $\text{CuS}$ ), although not a major ore of copper (*q.v.*), is found in many copper mines. Covellite, crystallizing in the hexagonal system, is of less frequent occurrence in nature than chalcocite (*q.v.*), the orthorhombic cuprous sulfide. Crystals are rare, the mineral being usually found as compact and earthy masses or as a blue coating on other copper sulfides. The dark indigo-blue colour is a characteristic feature, and the mineral was early known as indigo-copper. The name covellite is taken from N. Covelli, who in 1839 observed crystals of cupric sulfide encrusting Vesuvian lava, the mineral having been formed there by the interaction of hydrogen sulfide and cupric chloride, both of which are volatile volcanic products. Covellite is, however, more commonly found in copper-bearing veins, where it has resulted by the alteration of other copper sulfides, especially chalcopyrite. (L. J. S.)

**COVENANT**, an agreement made between two or more persons or groups. The word has various specific usages in history, the most important examples being the National Covenant of 1638 and the Solemn League and Covenant of 1643, and the covenant of the League of Nations; for these, see COVENANTERS and LEAGUE OF NATIONS. For the use of the word in law and in religion, see below.

**In Law.**—Covenant, in law, is a promise made under seal; i.e. in a deed. The promise may be positive (to do something) or negative (not to do something); the deed may be a deed poll with no party to it other than the covenantor, or there may be two or more parties. In modern times certain enforceable promises not made under seal, especially those relating to land, are sometimes loosely referred to as covenants. (See REAL PROPERTY AND CONVEYANCING, LAWS OF.)

The effects of putting a promise under seal are various. At common law, an agreement made without valuable consideration is unenforceable unless made under seal. Again, under the

statutes of limitation, lapse of time bars an action on a simple contract sooner than an action on a covenant. In most cases, however, a promise is put under seal not in order to secure the special consequences of a covenant but merely because the law requires the transaction to be effected by deed (as in the case of most formal dealings with land), and so any promises in the document perforce become covenants.

Covenants are used for a wide variety of purposes. Frequently they are merely incidental (though often important) parts of a transaction under seal, e.g., a lease, but sometimes they are of the essence. Thus it is common to find payments being made to persons or associations under deeds of covenant. However, it is in relation to land that covenants have a special importance. Three categories call for special mention:

1. Covenants for title are covenants in a conveyance of land whereby the grantor undertakes to protect the grantee and his successors in title against defects in title. In their broadest form, usually found in a warranty deed, they are against any defect in title. In England, however, the traditional covenants extend only to the acts or defaults of the grantor, of those claiming under him and of any predecessors in title back to the last purchaser for value; the benefit of all covenants for title runs with the land. In a quit-claim deed, no covenants for title are given to the purchaser.

2. Leasehold covenants are covenants contained in a lease. At common law a contract is normally enforceable only against the contracting party, but leasehold covenants which "touch and concern" the land are enforceable against the landlord and tenant for the time being, even though they are not the original lessor and lessee. (See LANDLORD AND TENANT.)

3. Restrictive covenants, or "equitable servitudes," show a further modification of the common-law rule. In *Tulk v. Moxhay*, 2 Ph. 774 (1848), it was held that a covenant to maintain Leicester square, London, uncovered with buildings would be enforced by injunction against a subsequent purchaser who bought with notice of the covenant. This decision lifted such covenants from the sphere of contract to that of property; thereafter they were equitable proprietary interests which bound all except a purchaser without notice. In the second half of the 19th century and the first half of the 20th, such covenants were widely used not only to protect individual plots of land but also to secure uniformity in the development of estates by means of schemes subjecting all plots within them to uniform and reciprocal restrictions: e.g., in prohibiting their use for any purpose save private residence, in securing a uniform "set back" and in prohibiting the erection of cheap buildings and unsightly outhouses. In many ways such schemes were the private equivalent of the public control subsequently imposed by town planning laws and zoning ordinances, but the modern tendency, particularly in England, is to rely more on public control and less on private restrictions.

The debate in the United States concerning covenants not to permit members of a specified race to buy or use a parcel of land should not obscure the usefulness of restrictive covenants as a constructive tool in community planning. Racial covenants in the U.S. are now unenforceable under *Shelley v. Kraemer*, 334 U.S. 1 (1948) and *Barrows v. Jackson*, 346 U.S. 249 (1953), which made judicial sanction of such covenants unconstitutional. In England the special rules for restrictive covenants apply only to negative covenants, but in the United States the courts have extended the rules to positive covenants as well. Covenants sometimes hinder rather than help, for they remain enforceable in perpetuity, even if obsolete. However, the courts will not enforce them if changed circumstances make this inequitable, and in England the Law of Property act, 1925, s. 84, provides also a statutory procedure for modifying or discharging covenants in specified circumstances. (R. E. MY.)

**In Religion.**—The Hebrew word *berith*, translated as "covenant," denotes a relation between two persons or groups, between God and man or between God and the created world. This relation is characterized as harmonious existence (peace), law and order, reconciliation, mutual or unilateral protection, trust,

etc. Covenant is established either unilaterally, by the gracious act of the more powerful of the two, or mutually, by two equals. Though the term is often used in the Old Testament to express a relation between two parties in the sphere of law, business, politics, individual friendship and tribal intercourse, it is employed in a more important theological sense to express the nature and meaning of man's fellowship with God.

**As a Form in Human Relations.**—The covenant may be a bond of allegiance between friends like David and Jonathan (I Sam. xxiii, 18), a treaty between two chieftains like Jacob and Laban (Gen. xxxi, 44 ff.) or simply a business agreement (I Kings v, 12). This type of covenant is not entirely secular, however, but frequently has religious sanctions (Gen. xxxi, 49).

**As a Religious and Social Institution.**—The relation between God and his people is understood as covenant. Yet here the term has a different meaning from its use in human relations. In the sphere of religion, covenant is a means whereby the deity is represented as binding his worshipers to himself by a sovereign act of grace and calling them to obedient allegiance and faithfulness. Among the Hittites and other peoples of the near east in the 2nd millennium B.C. there existed a form of political covenant which resembled the covenant between Yahweh and Israel. This is the so-called suzerainty treaty, in which the suzerain binds his vassals to himself unilaterally and makes stipulations which they are to observe. The suzerainty treaty, as well as other near-eastern types of covenant, has been adduced as evidence for the early age of the Old Testament covenant form. The covenant was the central institution which bound the tribes of Israel together in both the political and the religious sphere. This ancient institution was radically changed when the monarchy became the central authority in the 10th century B.C.

Two covenant ceremonies are primarily noteworthy: the covenant at Sinai (Ex. xix-xxiv; xxxiv) and the covenant at Shechem (Josh. xxiv). In the Sinai covenant, Israel is inaugurated as Yahweh's people and exhorted to obedience to the stipulations of covenant (the Ten Commandments). (See EXODUS; DECALOGUE; ARK.) In the Shechem covenant, the tribes were united into a league which worshiped Yahweh as the God who led them out of Egypt. (See JOSHUA, BOOK OF.) In the covenant ceremony the intermediary proclaimed God's gracious acts of salvation and exhorted the people to do God's will (Ex. xix, 4-6; xx, 1-17), and after the people's promise of allegiance (Ex. xix, 8; xxiv, 7) he presided at the sprinkling of the "blood of the covenant" and the sacred meal (Ex. xxiv). The intermediary of covenant—be he Moses, the priest or the king—represented the deity who bound his people to himself in the covenant rite. During and after the Exile (and in the New Testament), the intermediary became an eschatological figure and a symbol of God's new order of salvation (Isa. xlii, 6-9; cf. Heb. ix, 15).

**As a Symbol for the Promise of God.**—The oath of Yahweh, promising protection and guidance to an individual who somehow represented the totality of the people, is termed covenant. The covenants with Abraham (Gen. xv) and with David (II Sam. vii, 8-17; Ps. lxxxix, 19-37) constitute symbols which are frequently used in biblical tradition to denote God's promise of eternal faithfulness to his people (Isa. lv, 3; Luke i, 72-73).

**As a Symbol for God's Plan and Purpose in History.**—The notion that there is a given order in which man exists, and a purpose to his life and to the life of the religious community, is sometimes expressed by the term covenant. According to this view, God established an order of harmonious existence for all mankind in primeval times in the covenant with Noah (Gen. ix, 8-17); he promised protection to the people of Israel in the covenant with Abraham (Gen. xvii, 1-14); and he revealed his will to his people in the covenant with Moses at Sinai. This series of covenants symbolizes the stages in the purposeful forward movement of history from the natural world (Noah) to the elect people (Abraham) and the revelation of law through Moses.

**The "New Covenant."**—Jeremiah reinterpreted the ancient covenant notion and coined the term the "new covenant." It was a symbol for the new life which God would establish for his people in the future (Jer. xxxi, 31-34). (See JEREMIAH, BOOK OF.)

**Theological Meaning in the Old Testament.**—In its ancient usage, covenant symbolized the interrelation between God's grace and man's responsibility, between "gospel" and "law." It also stood for God's sovereignty as Israel's God. Although covenant was sometimes interpreted in a legalistic way (Deut. xxvi, 17–19), the institution of covenant presupposed God's forgiveness (Ex. xxxiv, 6, 7, 10; cf. Jer. xxxi, 34). In Jeremiah and Deutero-Isaiah, covenant becomes a symbol for God's entering upon the scene of history to create a new people unto Himself.

**Covenant in the New Testament.**—The life and death of Jesus is understood in terms of the new covenant which has replaced the old. The Last Supper is seen as a covenant rite in which the wine symbolizes the suffering of Jesus and the blood of the covenant (Ex. xxiv, 8; Mark xiv, 24; I Cor. xi, 25), Jesus being the intermediary of the new covenant (Heb. viii, 6; ix, 15). See HEBREWS, EPISTLE TO THE.

Goppelt, *Die Religion in Geschichte und Gegenwart: Handwörterbuch für Theologie und Religionswissenschaft*, ed. by Kurt Galling (1957). (T. K. T.)

**COVENANTERS**, the name given to Scottish Presbyterians who at various crises during the 17th century subscribed to bonds or covenants, notably to the National Covenant of 1638 and to the Solemn League and Covenant of 1643, pledging themselves to maintain their chosen forms of church government and worship. Private covenants for secular purposes had sometimes been made by Scots before the 16th century, but the fervour generated by the Reformation, and the dangers to which external threat and internal treachery constantly exposed the reformed church in Scotland after 1560, led its adherents to employ them for the safeguard of the new religion. After the first recorded religious covenant, the Bond of 1557, was made, the Scots circulated others at every time of danger.

It was in the 17th century, however, that the two most famous Scottish covenants were subscribed and that their adherents came to be known as covenanters. The National Covenant, first signed in Greyfriars' churchyard, Edinburgh, on Feb. 28, 1638, crystallized opposition to the attempt (1637) made by Charles I to introduce a new liturgy in Scotland. The Scottish assembly subsequently abolished episcopacy and in the Bishops' Wars of 1639 and 1640 took arms to maintain their religious liberty. The financial difficulties into which these wars brought the crown led to the summoning in England of the Long parliament (1640) and to the Civil War. Subsequently, by the Solemn League and Covenant (Sept. 1643), the Scots pledged their assistance to the parliamentary party in England on condition of the "reform" of the Anglican Church. The covenanting army thereafter took part in the Civil War, receiving Charles I's surrender in 1646. However, by the terms of "the Engagement" of Dec. 1647, by which Charles agreed to the Solemn League and Covenant, the king secured military assistance from the Scots. They also fought, after Charles I's execution, for his son Charles II, who signed the covenant in June 1650. In both campaigns they were defeated by the English.

The religious settlement forced upon Scotland by Commonwealth rule failed to satisfy the more rigid Presbyterians; the restoration of 1660, however, far from giving them greater satisfaction, ushered in the covenanters' era of martyrdom. All the legal sanctions of Presbyterianism were removed, episcopacy was re-established, and covenants were denounced as unlawful oaths. For 25 years the adherents of extreme reform suffered brutal persecution: three rebellions (1666, 1679, 1685) were cruelly suppressed. Relief was eventually brought by the English revolution of 1688, but constant persecution had rendered some of the covenanters so embittered and fanatical that they were unable to accept the new ecclesiastical settlement, which re-established Presbyterian church government but did not renew the covenants. See SCOTLAND: History; CIVIL WAR, ENGLISH.

**BIBLIOGRAPHY.**—D. H. Fleming, *Story of the Scottish Covenanters* (1904); J. K. Hewison, *The Covenanters* (1908); G. D. Henderson, *Religious Life in Seventeenth Century Scotland* (1937). (J. M.; X.)

**COVENANT THEOLOGY.** While the covenant idea ap-

pears in the systems of many early Reformed theologians (see BEZA, THEODORE; CALVIN, JOHN), the covenant or federal theology proper became widespread in the 17th and 18th centuries in England, Germany, Scotland, the United States and the Netherlands. Two covenants are understood to have been made: the covenant of works concluded by God with Adam as the federal head of the human race, and the covenant of grace, revealed and mediated by Christ as the second Adam. The classic statement was formulated by Hermannus Witsius in his *De oeconomia fœderum Dei cum hominibus* (1677). (H. W.)

**COVENT GARDEN**, a London square in which is situated the principal fruit, flower and vegetable market of England, lies north of the Strand in the city of Westminster. Originally a "convent garden" owned by the abbey of Westminster, from 1552 to 1918 it was the property of the earls and dukes of Bedford. During 1630–33 Inigo Jones designed the site for the fourth earl as a square bounded by vaulted loggias of which only a small portion survives on the north side. His church of St. Paul, in the Tuscan style, was rebuilt after a fire in 1795 by Thomas Hardwick. Grinling Gibbons, William Wycherley and Samuel Butler (author of *Hudibras*) are buried there and the ashes of Dame Ellen Terry are in a silver casket on the south wall. The market, established in 1671 under a charter of Charles II, was rebuilt during 1829–30. In 1961 the charter was revoked and ownership and control vested in a statutory authority charged with reorganizing and rebuilding the market by 1968. Contrasting with the bustling market, the dignified Royal Opera house (1858) stands to the northeast on a site which has been occupied by a theatre since 1732.

See E. Beresford Chancellor, *The Annals of Covent Garden and its Neighbourhood* (1930). (J. A. E. F.)

**COVENTRY, SIR JOHN** (d. 1682), English politician, remembered for his connection with the "Coventry act" of 1671, was the son of Sir John Coventry (d. 1652), a royalist and member of the Long parliament, and the grandson of Thomas, Lord Keeper Coventry. He was knighted in 1660 and entered parliament as member for Weymouth in 1667. His uncles Sir William and Henry Coventry were leading figures at court, but Sir John associated himself with the parliamentary opposition. In Dec. 1670, during a debate on a playhouse tax, he hinted that the king's interest in the stage was confined to actresses. Subsequently, he was waylaid (Dec. 21) by some guards officers led by Sir Thomas Sandys and his nose was slit. The outrage angered parliament and delayed the course of business until the passing of the "Coventry act," declaring assaults accompanied by personal mutilation a felony without benefit of clergy. An attempt was even made to bar the royal prerogative of pardon which had been exercised to protect Coventry's assailants. The king's responsibility for the attack need not be assumed, but he was fortunate in being shielded from further repercussions by an organized court party majority in the house of commons. Coventry died in 1682. (H. G. Ro.)

**COVENTRY, THOMAS COVENTRY**, 1st BARON (1578–1640), English lawyer, lord keeper of England between 1625 and 1640, was born at Croome in Worcestershire and was educated at Balliol college and at the Inner Temple, where he fell under the influence of Sir Edward Coke. Despite Francis Bacon's opposition, Coventry became recorder of London in 1616 and solicitor general in 1617. Under the patronage of the duke of Buckingham, whose ambition to obtain the office of lord high constable Coventry was later to oppose, his star continued to rise; he was appointed attorney general in 1621 and lord keeper in 1625, succeeding the unfortunate Bishop John Williams. Coventry, who was raised to the peerage in 1628, was loyal to his sovereign and a firm supporter of the royal prerogative on such issues as ship money. He was, however, more of a lawyer than a politician and he had but little influence in the inner councils of state. By nature a moderate man, he sought to mitigate the severity of the Star Chamber sentences and to prevent many of the court's illegal practices, such as the hanging of men for resisting press gangs. He cannot be wholly exculpated of responsibility for the excesses of the Star Chamber, but he was respected by the majority of his contemporaries and, as lord keeper, tried to remove many of the abuses of the court of chancery. He died

in London on Jan. 14, 1640, "in great honour, and much lamented by all the people." (G. H. J.)

**COVENTRY, SIR WILLIAM** (c. 1628–1686), English statesman, was one of the ablest and most respected figures in politics during Charles II's reign, and his failure to attain the highest offices of state can be attributed solely to his distaste for the vicious public life of his times. He was the fourth son of Thomas, Lord Keeper Coventry. He entered the Queen's college, Oxford, in 1642 but soon left to join the royalist army and later followed the court into exile. He returned to England in 1652 and by refraining from royalist activities survived unmolested to assist the Restoration. James, duke of York, made him his secretary in 1660 and he rode at the head of the royal procession into London in May 1660. He was elected member of parliament for Great Yarmouth in 1661 and at once interested himself in naval and commercial matters. He became a commissioner of the navy in 1662. His zeal and intelligence made him critical of the earl of Clarendon's leadership and it was ostensibly as an ally of Lord Arlington that he was knighted and made a privy councillor in 1665. Clarendon's account of him is consequently a jaundiced one, but they shared certain attitudes, notably their pessimism about England's capacity to fight out the naval war with the Dutch in 1665. Flimsy accusations of corruption made against Coventry and his growing sense of the government's inadequacy combined to depress his spirits, but in May 1667 he readily took office as a member of the treasury commission. In this post and as an outstanding speaker in the house of commons, he led a determined drive for administrative efficiency. Regarding Clarendon as an obstacle to this, he resigned from the duke of York's service in Sept. 1667, but he did not join in Clarendon's impeachment. Economies in expenditure became his principal concern during 1668 and the king's resentment at the restraints these imposed made it easier for the duke of Buckingham to secure Coventry's disgrace in 1669. Coventry was released after a short confinement in the Tower of London, utterly disillusioned with public service and determined never to take office again. Although his reputation made him a natural leader of the parliamentary opposition his independent spirit, breadth of mind and sense of moderation saved him from the grosser failings of partisanship. He shared many of the qualities and attitudes of his nephew the marquess of Halifax, but after assisting in the attack on the earl of Danby in 1675 he preferred retirement. Re-elected in 1679 he evaded serving in parliament after 1680. He died near Tunbridge Wells on June 23, 1686.

Coventry spoke out frequently against the French entanglement and during the exclusion crisis, when an attempt was being made to prevent the duke of York from succeeding to the throne, favoured the middle way of imposing limitations on a Roman Catholic king. Consequently he has been plausibly but wrongly credited with writing Pierre du Moulin's *England's Appeal From the Private Cabal at Whitehall to the Great Council of the Nation* (1673) and Halifax's *Character of a Trimmer* (1688). While in office Coventry earned the unstinted admiration of his subordinate Samuel Pepys, who saw "more real worth in him than in most men that I do know," but his principal satisfactions lay in increasing in the tranquil comforts of a country gentleman. Bishop Gilbert Burnet rightly estimated him "a man of the finest and best temper that belonged to the court" but "too honest to engage in the designs into which the Court were resolved to go." However, his career in opposition did not hinder his brother Henry from serving as secretary of state, 1672–80. (H. G. Ro.)

**COVENTRY**, a city and county borough of Warwickshire, Eng., 90 mi. N.W. of London and 10½ mi. N.N.E. of Warwick by road. Pop. (1961) 305,060. Coventry stands on undulating ground (highest point, 296 ft.). The Sherbourne and its tributary the Radford Brook meet near the centre, but are culverted along much of their course.

Two gates and some parts of the old city wall remain. During the violent German air raids of Nov. 1940 and April 1941 the centre of the town was laid waste and 50,479 houses were damaged. St. Michael's, the cathedral church, a fine Perpendicular building, was ruined except for the 295-ft. tower and spire. Like-

wise, all that remained of modern Christ church was the ancient spire of Grey Friars church, to which it was attached. These two, with the lofty steeple of Holy Trinity church, a Perpendicular cruciform building, still standing, are responsible for Coventry's being known as the "City of the Three Spires." The early 16th-century half-timbered Ford's hospital was seriously damaged, but carefully restored. Buildings that remain include St. John's or Bablake church (nearly a parallelogram on the ground plan, but cruciform in the clerestory), with a central tower; and St. Mary's hall, the centre of civic life since it was built by the Merchant Guild of St. Mary in the 14th century. The Great Hall, above a fine crypt, has a carved oak roof.

Work began in 1954 on the new cathedral, designed by Sir Basil Spence. The ruins of the old 14th-century cathedral have been incorporated in the whole cathedral plan and are used as a precinct to the new cathedral, as well as a Memorial Shrine of Reconciliation. Although contemporary in style, the new building harmonizes both with the old cathedral and modern buildings in the central area. Behind the high altar hangs a 70-ft.-high tapestry designed by Graham Sutherland. The ten 70-ft.-high nave windows face toward the altar: the five on the one side represent man's progress through life and the five on the other side God's revelation through history. On an exterior wall is Sir Jacob Epstein's bronze group of St. Michael and the Devil. Adjoining the cathedral is the Chapel of Unity administered jointly by Anglicans and Free churchmen. Elizabeth II laid the foundation stone in the new cathedral and the Chapel of Unity in 1956 and the cathedral was consecrated on May 25, 1962.

The ancient diocese of Lichfield and Coventry, formerly Coventry and Lichfield, was divided in 1836 when Coventry was included in Worcester diocese. The new diocese of Coventry was constituted in 1918.

Coventry (*Coventren, Coventre*) owed its early fame to the foundation of a Benedictine monastery there by Leofric, earl of Mercia, and his wife Godgifu (famous in legend as Lady Godiva; *q.v.*) in 1043. Their estate in Coventry descended in part to the earls of Chester and to Robert de Montalt and from him the manor of Cheylesmore in Coventry passed to Isabella, queen of Edward II, and then to Edward, the Black Prince, as duke of Cornwall; it remained part of the duchy for more than four centuries. Randulf or Ranulf de Gernon, earl of Chester (d. 1153), granted the earliest charter to the burgesses. This was confirmed with further privileges by Henry II, probably in 1182, and by nearly every succeeding sovereign until the 17th century. In 1345 Edward III gave Coventry a charter of incorporation. It first sent two representatives to parliament in 1295. Charters to hold markets and fairs were obtained in 1218, 1348 and 1445.

The origin of the popular phrase "to send to Coventry" (*i.e.*, to refuse to associate with a person) is uncertain. Lord Clarendon (*History of the Great Rebellion*) states that the citizens of Birmingham rose against small parties of the king's supporters and sent the prisoners they captured to Coventry.

From its early trading in raw wool, Coventry turned to cloth-making at the end of the 13th century, and increased in prosperity to become, before 1400, the centre of the midland cloth industry and the third most important town outside London. It acquired a reputation for its dyeing and the expression "as true as Coventry blue" became proverbial. The craft guilds associated with weaving and other trades played an important part in the life of the town, including the performance of the famous miracle plays, one of four extant collections. At the end of the 17th century ribbon weaving began to replace the declining cloth trade and increased to become, with watch- and clockmaking, the basis of the economy until the latter part of the 19th century. The industrial era began with the manufacture of bicycles in 1868 and further developed with automobiles in 1896. In 1904 rayon spinning was introduced and shortly after this the making of telephone and other electrical equipment.

The most important among a wide variety of industries are motor vehicles, agricultural machinery, guided missiles and turbo-prop engines, aircraft, machine tools; telecommunication equipment, radio, television, motion picture and other electrical equip-

ment; man-made fibres and woven labels and other ribbons.

King Henry VIII school for boys, now a direct-grant secondary grammar school (1545 charter), is in a Victorian building (1885), as is also an equally ancient foundation, Bablake school. There are two grammar schools for girls, eight comprehensive secondary schools, a technical college (a college of technology was opened in 1960) and a college of art.

A new city centre was built with a traffic-free shopping precinct occupying more than 100 ac. A feature of the central area plan is linked-rooftop car parking. The first full-scale theatre to be built by a civic authority in Great Britain was opened at Coventry in 1958. The city has many parks and open spaces totaling, with several commons, nearly 1,000 ac. The War Memorial park includes trees provided by relatives of the dead of two wars.

The boundaries of Coventry were several times extended between 1890 and 1932. Many street improvements were carried out, a bypass road was opened in 1939, and a city airport was established in 1936. A county of itself from 1462 to 1842, the city became a county borough in 1888. It now includes three parliamentary constituencies.

See William Dugdale, *The Antiquities of Coventre* (1765).

**COVERDALE, MILES** (1488?–1569), translator of the first printed English Bible and bishop of Exeter, was born at York and ordained priest in 1514(?) at Norwich. He became an Augustinian friar at Cambridge, graduating B.D., and under the influence of his prior, Robert Barnes, adopted first Erasmian then Lutheran opinions. Doubtless he met William Tyndale at the White Horse tavern, where the Lutherans gathered for discussion. When Barnes stood trial in London for heresy, and recanted in Feb. 1526, Coverdale accompanied him to help with his defense. Afterward he returned to Cambridge and devoted himself, with Thomas Cromwell's encouragement, to biblical studies. In 1528, however, he abandoned his convent, and clad as a secular priest began to preach in Essex against images and the Mass. In 1529, on Tyndale's invitation, he spent eight months at Hamburg helping him translate his Pentateuch, and then seems to have settled in Antwerp. In 1534 Coverdale translated into English J. Campensis' Latin paraphrase on the Psalms (1532), and was then employed by Jacob van Meteren, a Lutheran merchant of Antwerp, who did business with England, to translate the Bible. The book, dated Oct. 4, 1535, was printed by E. Cervicorn and J. Soter of Cologne, a city now safer for Lutherans than Antwerp. Coverdale wrote a dedication to the king, Holbein designed the frontispiece and the book was distributed, with Cromwell's support, by James Nicholson of Southwark, who himself reprinted it twice in 1537. Copies were installed in some churches, and Queen Anne Boleyn had one in her chamber. Nearly half its text (Ezra to Maccabees) was incorporated in Matthew's Bible (1537), which became the direct ancestor of the Authorized Version (1611). Being inexpert in Greek and Hebrew, Coverdale made his translation from five versions—Tyndale's incomplete version, Luther, the Vulgate, S. Pagninus' Latin (1528) and the Swiss-German (Zurich, 1534). Yet the result is surprisingly good, thanks to his modesty, judgment and easy style.

This task accomplished, Coverdale returned to England and threw himself into the cause of reform. He translated tracts by Luther and others, and compiled *The Concordance of the* [i.e., Tyndale's] *New Testament* (1535). He also sought to placate the conservatives by translating from the Vulgate first the New Testament (1538) and then the psalter (1540). But his chief work was to edit the Great Bible, which by royal injunction was to be installed in every church. This was a revision of Matthew's Bible based on Sebastian Münster's Latin (1535) in the Old Testament and Erasmus' Latin in the New. It was printed at Paris by F. Regnault, and was nearly finished when the French inquisition intervened. Coverdale and his publisher, Richard Grafton, fled with the types and printed sheets, and completed the book in London in April 1539; and a revised edition followed in April 1540. The psalter of the Great Bible was printed in the Book of Common Prayer (1549), where it still remains, being considered smoother and more singable than that of the Authorized Version. (See also *BIBLE, TRANSLATIONS OF*.)

Then came the reaction. The Six Articles (1539) laid stringent penalties upon married priests and all persons who denied transubstantiation. In 1540 Cromwell was beheaded and Barnes was burned at the stake. Coverdale fled overseas with his wife, Elizabeth Macheson or Sutherland, whose sister married John Macalpine (Maccabaeus), afterward professor and royal chaplain at Copenhagen. For three years Coverdale made Strasbourg his headquarters, translating tracts, writing a defense of Barnes and graduating D.D. at Tübingen university. He also visited Copenhagen, and wrote a tract describing how the Danes use the Lord's Supper. But in Sept. 1543 he moved to Bergzabern, about 40 mi. from Strasbourg, to become for four years headmaster of the town school, and assistant pastor of the church. In England his writings were denounced by proclamation and burned at Paul's cross in 1546.

After Henry VIII's death Coverdale returned to England about April 1548 and became almoner to Queen Catherine Parr, whose funeral sermon he preached in September. He was also royal chaplain and a notable preacher much in demand on important occasions. He contributed to the translation of Erasmus' paraphrases (1549) and at the duke of Somerset's request translated from German Otto Wermüller's *Precious Pearl* (1550). In 1549 he accompanied Lord Russell's army against the Devonshire rebels, preached on the battlefield after the victory near Exeter, and remained to pacify the diocese. For these services he was appointed bishop of Exeter by letters patent, was consecrated on Aug. 30, 1551, and won golden opinions by his episcopal zeal. In London he was regular in his attendance at the house of lords and served on the commission (1552) to reform the canon law.

With Mary I on the throne Coverdale lost his bishopric and on Sept. 28, 1553, was put under sureties by the council. He was in extreme danger, and prepared himself for the fire. He was saved by the king of Denmark, whose intercessions, prompted by Maccabaeus, persuaded the queen to grant him a passport to Copenhagen. Coverdale spoke no Danish and soon left Denmark and after a brief ministry to the English at Wesel he returned to Bergzabern in Sept. 1555. In Aug. 1557 with his wife and two children he joined the English colony at Aarau in Switzerland, and in autumn 1558 migrated to Geneva, probably in order to advise on the translating of the Geneva Bible of 1560.

After Elizabeth I's accession Coverdale started for England in Aug. 1559, and became for some time preacher and tutor in the household of the Puritan duchess of Suffolk. On Dec. 17, 1559, he joined with three other bishops in consecrating Archbishop Matthew Parker in Lambeth chapel, but he steadily refused to resume his bishopric of Exeter. He was old and poor, and his Puritanism, strengthened by residence abroad, rebelled against the ceremonies prescribed. All preferments he declined save a brief incumbency (1564–66) at St. Magnus, London bridge, but he often preached, and his sermons were highly esteemed. In 1563 he had an attack of plague. In 1565 his wife, Elizabeth, died, and he married in 1566 one Katharine, who survived him. He died on Jan. 20, 1569, aged 81, and was buried in the chancel of St. Bartholomew by the Exchange. This church was demolished in 1840, and his bones were transferred to the church of St. Magnus. No authentic portrait exists and nothing is known of his children.

Coverdale's life of courageous and unsparing labour wins respect. In the story of the English Bible his name stands second only to Tyndale's, and the musical rhythms of his psalter have enriched the devotions of countless Anglican worshippers. Coverdale's translations are rather free. Nourished on the cadences of the Latin language, he desires an easy movement and to please the ear by varying the stresses. For example: "I became dumb and opened not my mouth for it was thy doing. . . O spare me a little that I may recover my strength, before I go hence and he no more seen" (Ps. xxxix, 9, 13; cf. the Authorized Version: "I was dumb. I opened not my mouth, because thou didst it. . . O spare me that I may recover strength, before I go hence and be no more") and "My soul is athirst for God, yea even for the living God" (Ps. xlii, 2; cf. A.V.: "My soul thirsteth for God, for the living God").

See the edition of Coverdale's works by G. Pearson for the Parker society, 2 vol. (1844–46). See also J. F. Mozley, *Coverdale and His Bibles* (1953), which gives all sources. (J. F. Mozley)

**COVERLEY, SIR ROGER DE**, in English literature, a name taken by Richard Steele from the north country tune "Roger of Coverley." In the second number (March 1711) of the *Spectator* he is introduced as "a gentleman of Worcestershire of ancient descent, a baronet. His great-grandfather was inventor of that famous country dance which is called after him. . . He is now in his 56th year, cheerful, gay and hearty . . . rather beloved than esteemed." But Joseph Addison (*q.v.*) soon took the character into his own hands and developed it with subtler observation and humour than Steele ever had at command. Of the 30 numbers of the *Spectator* in which his character and surroundings are pictured, 20 are by Addison, eight by Steele, two by Eustace Budgell. In his courtesy and simplicity he shows some kinship with Don Quixote (*q.v.*) but his politics and churchmanship, like his paternal activity as master, landlord and magistrate, are native. The creation of Sir Roger marks and probably assisted the evolution of the boorish, hard-living Stuart squire into the benevolent, well-mannered and cultivated country gentleman which was the 18th-century ideal. Squire Western and Mr. Allworthy in Fielding's *Tom Jones* show the two types in sharp contrast and the popularity of Addison as a moralist may have contributed to the victory of the more humane and more civilized way of life.

**COVILHÃO** (COVILHAM, COVILHÄ), **PEDRO DE**, Portuguese traveler (late 15th–early 16th century) principally renowned for establishing the Portuguese connection with Ethiopia. He left no written narrative of his travels, but part of the valuable information in Francisco Alvarez' work is based on intelligence supplied by Covilhão. The dates of his birth (probably between 1450 and 1460) and death (sometime after 1527) are not known. He was a native of Covilhã in the province of Beira, Port. In early life he had gone to Castile and entered the service of Alfonso, duke of Seville, but with the outbreak of war between Castile and Portugal he returned to his native country.

It was in 1487 that King John II of Portugal sent for Covilhão and entrusted him, together with Alfonso de Paiva, with a mission whose aims were twofold: "to discover and learn about Prester John" whose Christian kingdom (in China, India or Abyssinia?) had long aroused the curiosity of European rulers; and to establish "where cinnamon is to be found, and the other spices which from those parts went to Venice through the countries of the Moors." The quest of the country of Prester John was no doubt motivated by the alarm which the Christian powers of Europe felt at the expansion of Islam, while the commercial rivalry of the Venetians made the diversion of the immensely valuable trade in spices, by direct route to Portugal, a highly desirable object. It appears from the account which Covilhão gave to Alvarez that earlier missions had failed for lack of a knowledge of Arabic and that Covilhão possessed this knowledge even before setting out on his travels.

While Paiva and Covilhão were proceeding eastward overland, Bartolomeu Dias (Dias de Novais, *q.v.*) discovered the sea route round the Cape of Good Hope. The two explorers traveled by way of Barcelona, Naples, Rhodes and thence to Alexandria and Cairo. There they joined a caravan of Moors and went on to Tor, Suakin and Aden, where they parted, Covilhão going to India, and Paiva to Ethiopia. Nothing more is known of Paiva's movements (he probably died in Ethiopia), but Covilhão reached Calicut whence he returned by way of Goa and Ormuz. After an expedition along the east coast of Africa as far as Sofala he retraced his steps to Cairo. There he met two emissaries of the king of Portugal bearing further instructions to look for Prester John. By one of them Covilhão sent a detailed report about his travels thus far. He then set out once more for Jidda (including, he claims, Mecca and Medina) and, by a somewhat circuitous route, finally reached Zeila (about 1490) whence he penetrated into Abyssinia. He was well received by the king, was given lands and honours, married an Abyssinian lady—but was not allowed to leave the country. When, 30 years later, the Portuguese embassy (1520), Rodrigo de Lima (including Alvarez) reached Abyssinia (1520), Covilhão with his knowledge of languages, customs and country proved to be of great use. He was also "an honourable person of merit and credit."

**COVINGTON**, third largest city of Kentucky, U.S., and seat of Kenton county, is on the Ohio river opposite Cincinnati. The Licking river, which empties into the Ohio, separates Covington from Newport. A 2,252-ft. suspension bridge, completed in 1866, spans the Ohio to Cincinnati; the Greater Cincinnati airport is located in adjacent Boone county. Commerce on the Ohio river was important in the early growth of the city and barges still operate the entire year. Population of the city of Covington, which is included in the Cincinnati (*q.v.*) standard metropolitan statistical area, was 60,376 in 1960 according to the federal census.

Located on a plain and partly surrounded by hills, the city has many fine attractions which include wooded Devou park, a 550 ac. recreational area with a natural amphitheatre seating approximately 40,000. Covington is the seat of a Roman Catholic bishopric; St. Mary's cathedral contains one of the world's largest stained-glass windows. Villa Madonna college (1921) and the University of Kentucky extension centre (1957), both located in the city, are but two of the institutions of higher learning in the Covington-Cincinnati area. The surrounding region specializes in tobacco, corn, hay and livestock. Numerous plants produce precision instruments, machine tools and dies, paper bags and cartons, electric equipment, canned fruits and meats, iron and steel products, fuels, building and road-surfacing materials, beverages and many other products.

The area was frequented by Daniel Boone and George Rogers Clark. The town was founded in 1815 and named after Gen. Leonard Covington of Maryland, a distinguished cavalry officer who fought and died in the War of 1812. The city was chartered in 1834.

A commission-manager form of government has been in effect since 1932. (J. C. CR.)

**COWARD, NOEL** (1899– ), English playwright and actor whose skilled dialogue and frank treatment of the period between World Wars I and II won him recognition as one of the most brilliant of the younger dramatists, was born at Teddington, Middlesex, on Dec. 16, 1899, and was educated privately. He made his stage debut as a child and became a very good actor. Among his most successful plays were *Hay Fever* (1925), *Easy Virtue* (1925), *Private Lives* (1930), *Design for Living* (1932), *Tonight at 8:30* (1935) and *Blithe Spirit* (1941). *Cavalcade* (1931), a historical play, differed from most of his work and was one of his greatest successes. Coward's extraordinary versatility was further evidenced by the number of musical plays and revues that he wrote and in most cases composed; they included *This Year of Grace* (1928), *Bitter Sweet* (1929), *Words and Music* (1932) and *Pacific 1860* (1946). He made many successful films, notably *In Which We Serve* and *Brief Encounter*, and wrote two volumes of autobiography, *Present Indicative* (1937) and *Future Indefinite* (1954), as well as a collection of short stories, *To Step Aside* (1939). He played in some of his own films and also appeared in cabaret, proving still further his versatility and ability as composer, writer and entertainer. (W. J. M.-P.)

**COWBANE**: see WATER HEMLOCK.

**COWBIRD**, the name given to the six species of the genera *Tangavius* and *Molothrus* in reference to their habit of associating with cattle in order to prey on ticks and, more especially, on insects that may be flushed from the vegetation. Cowbirds belong to the passerine family Icteridae, as do blackbirds, troupials and others. In most species the male is uniform glossy black and the female grayish brown. Like the old world cuckoos, they habitually lay their eggs in the nests of other birds. Young cowbirds, usually one to the host nest, customarily either displace competing nestlings or appropriate their food and may even exceed the foster parents in size. Some species parasitize many kinds of birds, but others utilize nests of only one or two kinds of orioles.

Best-known of the more northern species is the brown-headed cowbird (*Molothrus ater*) of southern Canada, the U.S. and northern Mexico. The bronzed cowbird (*Tangavius aeneus*) is found

from Arizona and New Mexico south to Panamá. The bay-winged cowbird (*M. badius*) of southern South America is unique in that it builds its own nest. (E. R. BE.)

**COWBOY.** "A boy who tends cows," the first definition sometimes given by standard dictionaries, is a statement of such profundity that it must be universally accepted wherever a boy performs that irksome chore. Such a one is not a cowboy, but a cow boy—two words. In North America, the word first cropped up in New York state during the American Revolution, and was there applied to a group of Tories who made a business of raiding the settlements that supported the American cause. This use of the term was both local and transient, passing with the termination of the Revolution. It is possible that the men who gathered cattle in the mountainous region of the south during colonial days were called cow boys, but proof of this is not available.

Indeed since the early days of the domestication of cattle, men have herded grazing cattle and driven them first from pasturage to pasturage and then from pasturage to market. Cortés used Aztecs enslaved as a result of his conquest as herdsmen. More than 200 years before the appearance of the cowboy in the U.S. in the 19th century, there were Mexican *vaqueros* (the Spanish and English words are virtually literal equivalents), whose relation to U.S. cowboys is explained below. The gauchos of South America appeared with the opening of the pampas to agriculture about 1850.

The cowboy—one word—is a product of the American west. His habitat, or range, began in the second tier of states west of the Mississippi, extended west to the Pacific, north into Canada and south into Mexico; in the U.S., it comprised 17 western states and covered about one-half of the United States. This western cowboy—the American cowboy—was not related in any way to the Tory raiders of New York or the colonial cattle gatherers of the south.

**The Cowboy in Texas.**—The American or western cowboy had his origin at the place where men began to handle cattle on horseback. It occurred where the five ingredients of open range cattle growing were found in juxtaposition: grass, water, cattle, horses and men. This combination was first made in extreme south Texas in an area shaped like a giant baseball diamond with San Antonio, the ghost town of Indianola, Brownsville and Laredo representing the four bases. The line from San Antonio southeast to Indianola separated the timbered country from the grassland, that from Indianola southwest to Brownsville was formed by the shoreline of the Mexican gulf, that from Brownsville northwest to Laredo followed the Rio Grande and separated Texas from Mexico. The fourth line, from Laredo northeast to San Antonio, bounded the vast plains and grasslands to the north and west, future home of the cowboy.

Here was open country where men could ride and grass grow; here was open climate where snow and ice come rarely; here were herds of wild horses, furnishing mounts for men hardy enough to ride them; here was the gulf where ships could anchor for cargoes of beef and hides; and here was enough fresh water for stock but not enough to grow trees or attract farmers. And here, as it turned out, were herds of cattle so wild and ferocious that only a man on horseback would or could approach them. All the elements were present except the American "boy who tends cows."

When the American "boy" came on the scene—1820-1836—he found this country already occupied, though sparsely, by Spaniards and Mexicans, and these had already perfected the art of handling cattle on horseback. The *vaquero* was already master of all the tools of the trade—horse, rope, saddle, spur, and branding iron (see **BRANDING**). In the revolution of 1836 which gave Texas its independence, the Texans took over the country north of the Rio Grande. They also took over the wild longhorns, the mustangs and all the techniques and tools that the Mexicans and their forebears had learned from the Moors and the Arabs before them. By the time the Texans had learned their lessons, Texas joined the union (1845) and the Texas cowboy took on the task of teaching what he had learned to his brothers north to Canada and west to the Pacific ocean.

It is difficult to say when the term cowboy came into use in Texas, but it was in use before 1842. In that year one Ewen

(or Ewing) Cameron went on the Mier expedition into Mexico, was captured and executed in the following year. Prior to that time, but subsequent to 1836, he headed up "a bunch of wild-riding, reckless Texans . . . who spent their time chasing longhorns and Mexicans soon after Texas became a republic. To the Mexicans they became the symbol of calamity. Then came the real cowboy as we know him today. . . ." (Reprinted from *The Best of the American Cowboy*, compiled and edited by Ramon F. Adams. Copyright 1957, University of Oklahoma Press. Used by permission.)

As long as the cowboy was confined to south Texas he did not acquire national recognition. It has been estimated that by the end of the Civil War the cattle in south Texas had increased to 5,000,000 head, and for them there had been little market. In 1866 they swarmed out of south Texas, finding markets in the growing industrial cities of the booming north. This movement resulted in laying out the cattle trails to such railheads as Sedalia in Missouri, Abilene, Dodge City and Ellsworth in Kansas, and finally to all the grassy states to the north and west. The cowboys were dispersed with the cattle throughout the cattle kingdom, and this movement was complete by 1890. It was in this era of handling cattle on the open range that the cowboy became a national figure.

**The Cowboy in the West.**—As the cowboy spread over the west he varied his practices, techniques and equipment to meet local requirements, but the changes were slight. For example, in the brush country and in the mountains he used a short rope but in the open plains he could use a long one. There were corresponding slight modifications in saddles, bridles and methods of riding. Though always a cowboy, or cowpuncher, he came to be known by different supplementary names in different areas, such as "buckaroo," "waddie," "vaquero" or "broncobuster."

The cowboy can never be understood apart from the work he did. The first thing to note about him is that he was not a boy, and he did not tend cows. He was a man, though usually a young one, and he handled cattle on a horse that nobody but a man could manage and with a rope that only an expert could use. Though his profession was that of handling cattle, he was not a cattleman nor a cowman—terms reserved for owners of cattle. He received a wage, and a small one, but he never thought of himself as a hired man and was reluctant to do anything that did not pertain to cattle. His loyalty was to the "outfit" and not to the owner, and his mores were derived from those he worked with rather than those he worked for. His occupation imposed many of his qualities on him. He was usually single, lived in a male society where every member understood every other member. Such a society imposes great restraint on its members. Loquacity is not long tolerated by men who live constantly together. The cowboy spent much of his time alone with his horse, and he became accustomed to silence and adept in expressing his ideas in few words. In the presence of strangers his taciturnity could be embarrassing.

The cowboy's clothes seemed picturesque to those who did not know their uses, but there was a reason for everything he wore from the toe of his shop-made boots to the crown of his Stetson hat. The cowboy did most of his work on top of a 900-pound horse whose movements were at best varied and at worst uncertain—running, turning, stopping, stumbling, or bucking. From such an ever-changing platform the cowboy had to do his work, swing the rope, throw it, and know what to do when he made his catch, whether a small calf or a steer that outweighed man and horse. His boots, built to leave the stirrup when he left the saddle, protected his ankles and legs; his hat had to stay on his head, however violent the action or high the wind, and it had to be of such quality that the brim would not tend to cut off his vision. Between his boots and his hat almost anything went, but it had to fit snug so that he had free use of arms and legs. Everything was tied on or tied down as for a ship in a storm. His bandana around his neck was not for looks but for use if he needed it to screen the dust from his nostrils or the sun from his cracked lips. His saddle, spurs, and bridle had to be of the best quality because they were subjected to the hardest use, and for any one of them to fail could bring disaster.

The cowboy was so dependent on his horse that he had great affection for him. Though the horses belonged to the ranch, a "string" of eight or ten was assigned to the cowboy to ride in succession, and nobody dared "tamper with his mount."

Two events in open range ranching brought the cowboy to the top of his performance. The roundup, one in the spring and another in the fall, was like the harvest when the crops were gathered. The long drive to Abilene, to Dodge City, or to a distant range or Indian reservation was the real adventure when anything could happen. At the end of the trail the cowboy was paid—maybe for a year's work—and he was likely to celebrate by spending all his money in a few days. After all it was his money, and he had another year in which to make some more. It was his vacation on these rare occasions that gave him the reputation of being a rowdy character. To judge him here would be as unfair as to judge a student at a football game or a businessman at a distant convention.

**The End of an Era.**—The era of the cowboy was closed by the coming of railroads to haul the cattle to market and of barbed wire to enclose the wandering animals. Together they ended the roundup of open range days and made the long drive impracticable and impossible. On the largest ranches, in the big pasture country, some semblance of the old practices remains, but only a semblance. The improved breeds of cattle could not stand the rough treatment that the longhorns flourished on.

Nobody knows how many cowboys there were at any given time. They never numbered more than a few thousand because a few cowboys could take care of many cattle and a great area. But of all the cowboys that rode the ranges from 1840 and after, nobody can name one as representative of the profession or trade. Among western characters an individual stands out as the top "bad" man, or "good" peace officer, or scout, or mountain man, but no individual can be cited as *the* cowboy. This namelessness may help to explain why he has become an abstraction and a myth, more perfect and certainly more glamorous in the imagination than he ever was in reality. He came on the scene at the very end of the pioneer period, came on horseback and with clothes and gear that made him seem romantic. He came so late that there were many to view him and spin around him the stuff of which myth is made.

The fiction writers picked him up, clothed him with silk, broadcloth and silver, put him on magnificent horses and sent him careening through a million pages of print, destroying evil and defending innocence and virtue, especially if these were wrapped up in attractive feminine form. The motion pictures took him fresh from the range and perfected his glamour and improved his prowess, and nightly this mythical cowboy rides to adventure and victory on thousands of motion-picture and millions of television screens all over the world. But in the words of Ramon Adams, "The West . . . knows that he has always been 'just a plain, everyday bow-legged human,' carefree and courageous, fun-loving and loyal. . . . He has been called everything from a cowpoke to a dude wrangler, but never a coward." (Reprinted from *The Best of the American Cowboy*, compiled and edited by Ramon F. Adams. Copyright 1957, University of Oklahoma Press. Used by permission.) The cowboy—real and mythical—became the subject of the greatest volume of literature and legend pertaining to any American worker. **COWDENBEATH**, a small burgh in Fifeshire, Scotland, 6 mi. E.N.E. of Dunfermline by road. Pop. (1961) 11,920. Cowdenbeath's principal industry is the mining of the Fifeshire coal field, with which its prosperity was linked. Peat is dug at Moss Morran, south of the burgh. Meetings in connection with the adoption and promulgation of the Covenant were held in the old parish church of Beath. Originally called Baith, the present form is said to have first appeared in Queen Victoria's *Journal*.

**COWELL, HENRY DIXON** (1897–1965), U.S. composer who in his early years introduced numerous novel devices into the modern technique of composition, was born in Menlo Park, Calif., March 11, 1897. He was virtually self-taught. Seeking new piano sonorities, he used massive chords, which he named "tone clusters"; these were struck on the keyboard with the fist and forearm. He applied such effects in numerous piano works he composed, including a piano concerto (1930). With the Russian engineer Leon Theremin he constructed the rhythmicon, an electronic instrument capable of producing different rhythms simultaneously. Cowell founded the *New Music Quarterly* (1927), devoted exclusively to publishing ultramodern music. Later he adopted a less radical style, composing music based on folk tunes gathered on world-wide travels. He wrote 15 symphonies; the 13th, *Madras Symphony* (1956–58), employs authentic Indian modes and rhythms; his *Persian Set* for chamber orchestra (1958) is derived from Persian tunes. Other works include *Synchrony* for orchestra (1930), *Tales from Our Countryside* for piano and orchestra (1941), and a set of eight pieces, each entitled *Hymn and Fuguing Tune*, derived from themes by an early American composer, William Billings. Cowell published *New Musical Resources* (1930) and (with his wife) *Charles Ives and His Music* (1955). He died in Shady, N.Y., on Dec. 10, 1965. (N. Sv.)

**COWEN, SIR FREDERIC HYMEN** (1852–1935), one of the most versatile British composers and conductors of his day, was born at Kingston, Jamaica, Jan. 29, 1852. At the age of four he was taken to England and in 1860 began studying with Henry Russell, Julius Benedict and John Goss. He later studied in Leipzig and Berlin. After his return to England in 1868 Cowen established himself as composer, conductor and accompanist. His music, including operas, oratorios, cantatas, six symphonies (of which no. 3, the "Scandinavian" [1880], was the most successful), orchestral suites and many songs, though variable in quality, is graceful in style and skilfully written. Cowen was active as a conductor in London, Glasgow and Manchester and as an adjudicator at music festivals throughout the British Isles. He was knighted in 1911. He died in London on Oct. 6, 1935. (H. Ru.)

**COWEN, JOSEPH** (1831–1900), English orator, politician and journalist who was a highly individualistic champion of radical causes, was born at Blaydon, near Newcastle upon Tyne, on July 9, 1831. His father, Sir Joseph Cowen, was a Northumberland mine owner and proprietor of the Blaydon brick and fire-clay works. Joseph Cowen was educated at Edinburgh university, where he made his name as an orator. From his student days he showed enthusiasm on behalf of advanced radicalism at home and national movements abroad. He sympathized with the Chartists, was an ardent parliamentary reformer and, though active in the family business, a supporter of trade unionism. He was the friend of Kossuth, Mazzini, Garibaldi and A. I. Herzen and of Polish exiles, and he made generous and bold efforts to help their conspiracies in Europe. Accordingly he was intensely antislavery. He was a strong advocate of the North in the American Civil War and also of Home Rule for Ireland. In 1859 he bought the *Newcastle Chronicle*, which he made famous among provincial journals and through which he exercised great influence on opinion in the north of England. Cowen succeeded his father as member of parliament for Newcastle in 1874. He called himself a radical and was soon known for his independence of party. He championed, against Gladstone, Disraeli's policy toward Russia in the near eastern crisis of 1875–78 (see **ENGLISH HISTORY: The Victorian Age, 1837–1901**), and he was a pioneer of imperial federation. In the 1880s he opposed the introduction of the closure into the procedure of the house of commons and campaigned against what he regarded as the interference of the National Liberal federation in his constituency. He retired from parliament in 1886, but continued to play an important part in northern politics. He died on Feb. 18, 1900. (D. E. D. B.)

**COWES**, an urban district and seaport in the Isle of Wight, Hampshire, Eng., is on the Solent (q.v.) 11 mi. S.S.E. of Southampton. Pop. (1961) 16,992. West Cowes is separated from East Cowes by the picturesque estuary of the Medina river, the two towns (combined as an urban district in 1933) lying on opposite

sides of its mouth at the apex of the northern coast of the island. A floating bridge connects them. The port between the two towns is the main port on the island.

The Royal Yacht squadron (founded 1815) has had its headquarters since 1856 at Cowes castle (1540), built by Henry VIII for coastal defense. There are six other yacht or sailing clubs and the annual regattas culminate in Cowes week (the first week in August). There are shipyards and aircraft, rope and sailmaking works. East Cowes castle (1799) was built by John Nash the Regency architect for his own residence. He died there and is buried in the churchyard of St. James close by. Osborne (q.v.), to the southeast, was the marine residence of Queen Victoria from 1845 until her death. On Nov. 22, 1633, two vessels, the "Ark" and the "Dove" carrying the founders of Maryland under Leonard Calvert left Cowes for America, an event commemorated by a tablet on Victoria parade.

**COWL, JANE** (JANE COWLES) (1884-1950), U.S. actress, was born in Boston, Mass., on Dec. 14, 1884. She made her stage debut at the Belasco theatre, New York city, in *Sweet Kitty Bellairs* in 1903. Her most important plays were *A Grand Army Man*, *The Easiest Way*, *Within the Law*, *Lilac Time*, *Information*, *Please*, and *Smilin' Through*, the latter three of which she was the co-author.

She died at Santa Monica, Calif., on June 22, 1950.

(S. W. H.)

**COWLES, HENRY CHANDLER** (1869-1939), U.S. botanist and one of the foremost pioneer investigators in plant ecology in America, was born in Kensington, Conn., on Feb. 27, 1869. He graduated from Oberlin college in 1893 and in 1898 he received the Ph.D. degree from The University of Chicago. He was instructor of botany at The University of Chicago from 1902 to 1907, assistant professor from 1907 to 1911 and associate professor from 1911 to 1915. In that year he was made professor, and in 1925 he became chairman of the department of botany. He made valuable researches in physiographic and comparative ecology, especially the ecological relations of dune vegetation. He also made important contributions on the floristics of the Chicago region and on trees as indicators of past topographic conditions. Cowles's writings include *Vegetation of Sand Dunes of Lake Michigan* (1899); *Plant Societies of Chicago* (1901); *Textbook of Plant Ecology* (1911); and *Plant Societies of Chicago and Vicinity* (1913). He was editor of the *Botanical Gazette*, 1925-34.

**COWLEY, ABRAHAM** (1618-1667), English poet and essayist, last of the Metaphysicals and first of the Augustans, was born in London, and educated at Westminster school and at Trinity college, Cambridge. On being expelled by the Parliamentarians in 1643, he moved to Oxford where he was a member of the Falkland circle. He followed the queen to France in 1645 and was appointed her cipher secretary, acting also as a royalist agent in various capacities. On returning finally to England in 1656, he became associated with the group of men who prepared the way for the Royal society. He wrote *A Proposition for the Advancement of Experimental Philosophy* (1661) and, though never a Fellow of the Royal society, was always considered a pioneer of the society's principles. After 1660 he retired to live a quiet scholarly life in the country, where he interested himself in horticulture, on which he corresponded with John Evelyn, and also in medicine. He died at Chertsey on July 28, 1667.

Cowley is the type of the transitional writer. Remarkably versatile and adaptable, he produced verse and prose, usually of good quality, in almost every style current in his lifetime. While still a schoolboy he wrote verse of a Spenserian kind in *Poetical Blossoms* (1633) and also lyrics in a more natural style reminiscent of Ben Jonson. His prose shows a steadier development than his verse but, as one might expect, the metaphysical verse usually shows signs of decline and the newer work of immaturity.

The term "Metaphysical Poets" originated in Dryden's critical collocation of Cowley with Donne. Dr. Johnson later made a number of trenchant comments on his use of the conceit, yet he took him as not only the representative poet of this school but as "undoubtedly the best." Cowley's metaphysical poetry appeared mainly in *The Miscellanies* (1656) and *The Mistress* (1647 and

1656). His "Ode of Wit" discusses and exemplifies the spirit of this poetry. His work lacks the imaginative concentration and tension of the great Metaphysicals: his conceits tend to be decorative expressions of a simple theme rather than embodiments of subtle and passionate feeling. The language is close to speech and there is a noticeable air of social decorum. "On the Death of Mr. Crashaw" is the most emotional of Cowley's metaphysical poems. It is in couplets, the conceits are on a large scale and the grand style and organization of the poem suggest his neoclassical successors. *The Mistress* belongs with the Cavalier collections and is heavily indebted to Donne. Cowley sets out also to rival Edmund Waller. The best poems have a racy dramatic quality of some originality. "On the Death of Mr. Hervey" belongs with this work in date though not entirely in manner. It is a poignantly personal account of a friendship, informal in language and quiet in tone.

An unfinished epic, *The Davideis* (1656; written c. 1640) and the *Pindarique Odes* (1656; written in the early 1650s) have their links backward, particularly the former, where conceits make up a large part of the imagery, but their main interest is as precursors of the future. *The Davideis* is a landmark in the history of the couplet and is composed according to strict neoclassical principles. In the odes, Cowley began with "imitations" of Pindar's "way and manner of speaking" rather than translations, and went on to independent poems in irregular stanzas and conversational style which have considerable intrinsic interest. "To the Royal Society" (1667) is a powerful and dignified address. Cowley established the form in England.

Cowley's later and more decidedly neoclassical work is contained in *Essays in Verse and Prose* (1668). The essays in prose vary from Baconian and Brownian sentences to more extensive passages which, as Johnson says, are "easy without feebleness and familiar without grossness." With Dryden's prefaces they mark the emergence of a modern prose suitable for most purposes. Cowley's theme is the Epicurean-Horatian ideal of a life of cultivated retirement in a "moderate plenty." He writes personally, with many literary allusions, but few references to the contemporary scene or to his own scientific interests. The verse essays in the form of odes and sets of couplets, supplement the prose with mild satires on "the Great Vulgar, and the Small" and celebrations of the "old Plebeian" in his "Sabine field."

Cowley was the leader of the literary world in later life and was widely read in the 18th century. Since then his reputation has gradually settled down to that of an important and representative minor writer with a limited number of achievements approaching greatness.

Grosart (1881); *The English Writings of Abraham Cowley*, ed. by A. R. Waller (1905-06). See also Johnson's *Life* (1779); J. Loiseau, *Abraham Cowley, sa vie, son oeuvre* (1951); A. H. Nethercot, *Abraham Cowley* (1931); G. Walton, *Metaphysical to Augustan* (1955).

**COWLEY, HENRY RICHARD CHARLES WELLESLEY, 1ST EARL** (1804-1884), British diplomat who as ambassador to Paris from 1852 to 1867 played a crucial role in the diplomacy of the Crimean War period, was born in London, June 17, 1804. He was the eldest son of Henry Wellesley, 1st Baron Cowley (1773-1847), British ambassador successively in Spain, Austria and France; nephew of the 1st duke of Wellington; and brother of Gerald Valerian Wellesley (1809-82), dean of Windsor and confidant of Queen Victoria. He was educated at Eton and at Brasenose college, Oxford, and entered the diplomatic service in 1824, serving in turn at Vienna, The Hague, Stuttgart, Constantinople, Bern and Frankfurt. In Feb. 1852 Lord Granville chose him to succeed Lord Normanby as British ambassador at Paris.

The appointment, though unexpected, proved excellent. For many years the ambassador to Paris had changed with each change of government in London (Normanby's predecessor, in 1841-46, had been Cowley's own father), but Cowley proved so able and trustworthy that he held his post for 15 years, under eight ministries. Personally shy and even unsociable, he was absolutely straightforward and a master both of tact and firmness. Strong

as well as weak British foreign secretaries and the vacillating emperor Napoleon III alike relied on his judgment and advice. He conducted with exemplary skill the delicate negotiations with the French which resulted in the alliance that fought the Crimean War; held the alliance together—no easy task—while the war went on; and with his friend the 4th Lord Clarendon (*q.v.*) was a plenipotentiary at the peace congress of Paris which concluded it in 1856. Next year he was advanced to an earldom. It was largely because of Cowley's abilities and discretion that peace was preserved between England and France, both when French opinion was exacerbated over the Orsini affair in 1858 (see ORSINI, FELICE) and when English opinion was exacerbated over the French annexation of Savoy in 1860. He helped to negotiate Richard Cobden's trade treaty of that year, and continued to exercise a pacific influence over the emperor for the rest of his time at Paris. He was created knight of the Garter in Feb. 1866, and retired in July 1867. Cowley died in London on July 15, 1884.

**COWLEY FATHERS**, the popular name for the SOCIETY OF ST. JOHN THE EVANGELIST, the oldest Anglican religious community for men, founded in 1866 by Richard Meux Benson (1824–1915) at Cowley, Oxford. It combines an austere and profound inner life with preaching and missionary work. The society also has houses in the United States, Canada, South Africa, India and Japan.

See P. F. Anson, *The Call of the Cloister* (1955); M. V. Woodgate, *Father Benson* (1953). (A. MacD. A.)

**COWPEA**, the name used in the United States for the cultivated forms of *Vigna sinensis* especially, but also for *V. catjang*, two legumes closely related to the common beans. In most other countries the cowpea is known as China bean or black-eyed bean; botanically it is a bean rather than a pea. The plants are rambling tender annuals, probably native to India and Iran, but their cultivation extended to China at an early date.

In the U.S. the cowpea is extensively grown in the south as a hay crop, as a green-manure crop and as shelled beans for human consumption. More than 200 varieties of *V. sinensis* have been recognized under the generic terms "black-eyed pea" and "corn-field pea."

JOHN H. GERARD

COWPEA OR BLACK-EYED PEA (*VIGNA SINENSIS*)

(J. M. BL.; X.)

**COWPER, WILLIAM** (1731–1800), was one of the most widely read English poets of his time, and even today some of his hymns are sung throughout the English-speaking world. He brought a new directness into nature poetry; he wrote of the common joys of everyday life; he expressed the feelings of the humanitarian movement of his age. Yet the circumstances of his life did little to prepare him for his place as a popular and influential poet, for he was a recluse and, at times, a madman and, like William Blake, was always at odds with the predominantly pragmatic philosophy of his time.

William Cowper (who, like the rest of his family, pronounced his name "Cooper") was born at Great Berkhamsted, Hertfordshire, on Nov. 26, 1731. His father, who was rector of the parish, was a nephew of the first Earl Cowper; his mother, Anne, was related to the family of the poet John Donne. After the death of his mother when he was six, an event which greatly affected the young boy, Cowper was sent to a boarding school at the nearby village of Markyate or Market Street where the bullying he endured brought on a nervous inflammation of the eyes. He then moved on to Westminster school in London where he seems to have been reasonably happy. He left Westminster in 1748, and went to live in 1750 at the house of Mr. Chapman, an attorney, with whom he studied law. He was admitted in turn to the two Inns of Court,

the Middle and Inner Temple, was called to the bar in 1754, and took chambers in the Middle Temple in 1757. Cowper was obviously unsuited to a career in law, but his student days were important because it was then that he made friends with some of the young wits of the time (Charles Churchill, Robert Lloyd and the future lord chancellor, Edward Thurlow). It was then, also, that he got to know his cousins, Harriet and Theodora, daughters of Ashley Cowper of Southampton row, and fell deeply in love with Theodora. For a time there was an engagement between the two, but Ashley Cowper insisted that it should be broken off on the grounds that his nephew was without prospects and was showing signs of mental instability. William Cowper, indeed, was beginning to cause some anxiety to his friends. His father had died in 1756, leaving him no great fortune, and his family used their influence to obtain for him the offer of two administrative posts in the house of lords—that of reading clerk and that of clerk of the committees. Unfortunately the appointment entailed a formal examination at the bar of the house, the prospect of which so disturbed Cowper that he tried to commit suicide and had to be confined for 18 months in an asylum at St. Albans.

It was during this period of insanity that he began to be troubled by the religious doubts and fears which returned, intermittently, throughout his life. In a dream he saw himself shut out from the band of Christian worshippers and woke to believe that he was predestined to inevitable damnation. But if religion provided the chief horror of his madness, it provided also the comfort of his convalescence. In June 1765 he was able to leave the asylum, and his friends, who had contributed toward a small pension, arranged for him to live at Huntingdon to be near his brother Jack who was a fellow of St. Benet's college, Cambridge. At Huntingdon he made friends with the Unwins (the Rev. Morley Unwin, his wife Mary and their son and daughter) with whom he took lodgings in Nov. 1765. The Unwins were a pious, Calvinist, Church of England family, fervent supporters of the evangelical revival which was then a powerful force in English society. Cowper's two years with them were the happiest of his life and when, in July 1767, Morley Unwin was killed by a fall from a horse, it was arranged that the poet should take up residence with the widow and her children at Olney, in Buckinghamshire, in order to be near John Newton, curate of the parish, with whom he had become acquainted. Newton, one of the leaders of the evangelical movement, introduced Cowper to a life of hymn singing, sick-visiting and acts of charity, which was too vigorous for the poet's frail nervous system and led to a return of his doubts and melancholy, though it must be noted that it was not from Newton that he derived his delusions about damnation. To divert the poet from his melancholy Newton suggested that the two of them should co-operate in writing a book of religious verse which appeared eventually in 1779 as the *Olney Hymns*, Cowper's contributions being marked by a "C." The work of composition failed to revive his spirits and in 1773 he relapsed once again into melancholic near-madness, which put an end to any thoughts of marriage with Mary Unwin.

During this illness he stayed at the vicarage under Newton's care, and though by the summer of 1774 he was well enough to return to his own house, Orchard Side, he was greatly changed. He had lost all his religious fervour and sought distraction from fears of damnation by gardening and the keeping of tame hares. In 1780 Newton left Olney to become rector of St. Mary Woolnoth in London, and though his absence may have been something of a relief, it left Cowper with much spare time. He decided to occupy himself, therefore, with the writing of poetry and, Mrs. Unwin having suggested as a subject "The Progress of Error," he began composing the six moral satires which gave him valuable practice in versifying.

About this time he passed into a comparatively cheerful phase (as can be seen from two of the satires, "Conversation" and "Retirement") due largely to his friendship with Lady Austen, the sister-in-law of the vicar of the nearby parish of Clifton. It seems likely that Lady Austen, who was a widow, may have contemplated marriage with Cowper but this was unthinkable to him and the friendship cooled. In 1784 she left Olney and did not

return, but before leaving she had given Cowper the story which he made into the ballad "The Diverting History of John Gilpin," soon to be sung all over London, and also had playfully suggested that he should write about the sofa—an idea which grew into *The Task*. This latter, a long, discursive poem intended "to discountenance the modern enthusiasm after a London life, and to recommend rural ease and leisure, as friendly to the cause of piety and virtue," was published in 1785, together with "Tirocinium, or A Review of Schools," and was an immediate success. His fame brought him new friendships and a renewal of old ones. In particular, his cousin Harriet Cowper, now Lady Hesketh, spent much time at Olney and persuaded the poet to move to a larger house at Weston, a neighbouring village, where he could be near his Roman Catholic friends, the Throckmortons. He was at work by this time on his translation of Homer, a long laborious task, the revision of which continued to trouble him for many years after the publication, in 1791, of the first edition. His spirits and health began to break down under the strain, and there were occasional bouts of madness. In 1792, Mrs. Unwin had a second paralytic stroke from which she remained an invalid for the rest of her life. Cowper now began to compile an edition of Milton which he failed to complete. The work brought him the friendship of William Hayley, famous for his association with William Blake and George Romney, who was interested in the same poet. Largely through Hayley's efforts Cowper was awarded a pension of £300 a year, but his health continued to deteriorate, and in 1795 his cousin John Johnson ("Johnnie Johnson of Norfolk") took the poet and Mrs. Unwin to East Anglia where, in Oct. 1796, they finally settled at East Dereham. It was hoped that the change of scene would be of benefit to Cowper, but, after the death of Mary Unwin in Dec. 1796, he gradually sank into lethargy and despair from which he never emerged. He died on April 25, 1800, and was buried in East Dereham church.

Though Cowper's life was a sad one, his poetry is largely the poetry of pleasure. He celebrates not the rare and strange but things that are ordinary and even humdrum—the greenhouse, the garden, the fireside, the cup of tea. Some 18th-century poets (such as James Thomson) wrote of wild, romantic country, while others (such as Pope) wrote of parkland and well-managed estates, but Cowper was content to describe the unspectacular midland scene of hedges, lanes, ditches, rivers, haystacks and ploughland. In the long descriptive passages of *The Task* he seems not to be constructing a landscape but rather to be recalling his impressions in a series of vivid vignettes. His sketches of birds and other creatures are as lively as a woodcut by Thomas Bewick. From no poet before him and from few since can there be compiled so rich an anthology of the details and minutiae of nature accurately observed and felicitously worded. His style sometimes has a certain stiffness, for he often essayed a mock-Miltonic manner, but at his best he has a quiet, conversational ease and when moved by a subject which stirred him greatly (such as the slave trade or cruelty to animals) he could rise to a true eloquence. In his comparative simplicity of language, his feeling for nature and his sympathy with the poor and oppressed, he may be seen as one in revolt against the trend of much 18th-century verse and as a forerunner of Burns, Wordsworth, Coleridge and other romantic poets. He was no wit, but he had the saving grace of humour which gives charm to his slightest pieces, some of which, such as "The Colubriad," are excellent examples of light verse. "The Poplar-Field" and one or two other short lyrics reveal an ear for melody which might not have been guessed from a reading of his blank verse, while "The Castaway" poignantly shows the tragedy which was never far below the surface of his mind.

It is this same combination of poignancy and humour which makes Cowper's correspondence so attractive and puts him among the very best letter writers in the English language. The best of his hymns, too, are important. More personal in tone than is usual in a successful hymn, they evoke an imaginative response by their use of powerful imagery drawn from nature and from the Bible. "God moves in a mysterious way" and "Oh! for a closer walk with God" have become part of the folk heritage of Protestant England.

**BIBLIOGRAPHY.**—The two most important bibliographical studies are N. Nicholls, "Early Editions of William Cowper," *The Bookman* 100 (1931); and Lodwick Hartley, *William Cowper: the Continuing Evaluation. An Essay and a Bibliography of Cowperian Studies, 1895-1960* (1960). A bibliography of early editions of the poems is included in the standard modern ed., *The Poetical Works*, ed. by H. S. Milford (1903; 4th ed., 1934); the *Correspondence*, 4 vol., ed. by T. Wright (1904); *Unpublished and Uncollected Letters*, ed. by T. Wright (1925). A useful modern selection of the letters is that made by E. V. Lucas, with notes by M. L. Milford (1911) in the "World's Classics." The first important life was W. Hayley's *Life and Posthumous Writings* (1803-04); followed by Robert Southey's much more valuable *Life and Works*, 15 vol. (1835-37; reprinted in 8 vol., 1855-55, in Bohn's Standard Library). Shorter lives by T. Taylor (1835) and G. Smith (1880, English Men of Letters series). Of later studies, the following are the most important: H. I. A. Fausset, *William Cowper* (1928); Lord David Cecil, *The Stricken Deer* (1929), based largely on the poet's letters; G. Thomas, *William Cowper and the Eighteenth Century* (1935, rev. ed. 1948); L. C. Hartley, *William Cowper, Humanitarian* (1938); N. Nicholson, *William Cowper* (1951), "William Cowper," *Writers and their Work*, no. 121, British Council and National Book League (1960); C. Ryskamp, *William Cowper of the Inner Temple, Esquire* (1959). See also V. Woolf, *The Common Reader*, second series (1932); B. Martin, *John Newton* (1950). (N. C. N.)

**COWPER, WILLIAM COWPER, 1ST EARL** (c. 1665-1723), English lawyer and a leading Whig politician who was the first lord high chancellor of Great Britain, was the elder son of Sir William Cowper, 2nd baronet. Educated at St. Albans school, Cowper was called to the bar in 1688. Having promptly given his allegiance to William of Orange, he was made recorder of Colchester in 1694 and from 1695 to 1705 represented first Hertford and then Beeralston in the house of commons. He enjoyed the reputation of being the most distinguished Whig barrister and one of the most effective parliamentary orators of his generation.

Having survived the odium of a murder charge brought against his brother Spencer (the grandfather of William Cowper the poet), Cowper was appointed lord keeper of the great seal in 1705. In 1706 he succeeded to his father's baronetcy and was raised to the peerage as Baron Cowper. In 1707, after the union with Scotland, he was appointed the first lord high chancellor of Great Britain. He resigned in 1710. On the death of Queen Anne, he was made one of the lords justices for governing the country during the interregnum, and Cowper wrote a paper entitled *An Impartial History of Parties* for George I's guidance. He was reappointed lord chancellor in 1714, supported the impeachment of Lord Oxford in 1715 and presided, in 1716, as lord high steward at the trials of peers charged with complicity in the Jacobite rising of 1715. In 1718, shortly after receiving the titles Viscount Fordwich and Earl Cowper, he resigned, probably because his intimacy with, and support of, the prince of Wales had incurred George I's enmity. He remained an active member of the house of lords until his death, at Colne Green, Hertfordshire, on Oct. 10, 1723.

Cowper was not a profound jurist, but he sought to remove many of the abuses of his court, refusing to accept the traditional new year gifts and attempting to expedite chancery procedure. A man of considerable personal charm, he was twice married. His son William succeeded to the family honours. (G. H. J.)

**COWPER STOVE**, an apparatus for preheating the air blown into a blast furnace (*q.v.*). One of the most important steps in successful and economical blast-furnace practice is accomplished by heating the air blast prior to its introduction into the furnace. While the general principle of the use of preheated air was originally employed by James Neilson in 1828 in Glasgow, Scot., it was not until 1860 that E. A. Cowper invented the first economical, intermittent type of hot-blast stove. This is a vertical cylindrical steel shell lined with fire brick and with the interior separated into a chamber for the combustion of waste hot-blast furnace gases and a regenerative chamber filled with a checkerwork of refractory brick heated by the burned gas. After the checkerwork has been heated the gas is shut off and the air blast passes through the regenerative chamber to be preheated on its way to the blast furnace.

The efficiency and thermal capacity of the stove are governed by the surface area of the brick checkers and their mass. The brick, exposed on both sides to heating, is generally about 14 in. thick. The normal air blast period is about 90 minutes with a

blast temperature ranging from 1,000° up to 1,800° F.

For another application of heat regeneration see **CRUCIBLE STEEL**. See also **IRON AND STEEL INDUSTRY: Blast Furnace Plant: Stoves**. (D. S. E.)

**COWRIE** (COWRY), a common name for a handsome, shelled marine gastropod mollusk of the family Cypræidae, a great favourite with shell collectors because of its rich colouring and naturally polished shell. More than 160 living species are known. They live in shallow water, and are found principally in the Indo-Pacific region, though several species are found in warm American waters.

Cowries have a striking appearance when seen alive. The edges of the mantle are folded over the shell, covering a large part of its surface, and are provided with branched appendages. In the young cowrie the shell is like that of a normally coiled snail, the lip of the aperture being simple and the spire acute and prominent. In the adult the outer lip is very large, the shell is inrolled so that the spire is nearly hidden, and the internal wall between the various whorls is resorbed.

The shells of the money cowrie, *Cypraea moneta*, have been used by certain African tribes as currency (see **CURRENCY, PRIMITIVE**), and those of other species are widely employed as ornaments and charms against evil, sterility, etc. (see **DRESS: Origins**). *Cypraea aurantia*, the golden cowrie, is worn as a symbol of rank in the Fiji and the Tonga islands.

See also **SHELLS AND SHELL COLLECTING**. (W. K. E.)

**COWSLIP**, a common name for several herbs including a garden perennial, the primrose *Primula veris*, and a wild flower, the marsh marigold. See **MARSH MARIGOLD; PRIMROSE; PRIMULACEAE**.

**COW TREE** (MILK TREE), any of several tropical American trees whose milky latex, which flows out in quantities when a notch is cut in the trunk, is sweet and pleasant tasting. The group includes *Brosimum utile* (family Moraceae) native to Venezuela; and several species of *Couma* (family Apocynaceae) and *Mimusops* (family Sapotaceae). The milk tree of Brazil, *Mimusops huberi*, produces a latex having the consistency and richness of thick cream; it is used as a nutritive drink and as glue. The timber of this tree is valuable and the fruit is edible.

**COX, JACOB DOLSON** (1828–1900), U.S. army officer, political leader and educator, was born on Oct. 27, 1828, in Montreal, Que. He was reared in New York city, and studied in a law office in 1842–44. Working in a broker's office in 1844–46, he came under the influence of Charles G. Finney, whose daughter he afterward married. In New York city he also prepared himself for the ministry. He attended Oberlin college, Oberlin, O., and graduated in 1851, having given up his theological studies in rebellion against Finney's dogmatism. From 1851 to 1853 he was superintendent of schools at Warren, O. In 1853 he was admitted to the Ohio bar and in 1859 was elected to the state senate. Appointed by the governor of Ohio as one of three generals of militia in 1860, he studied tactics, strategy and military history.

During the American Civil War he raised troops for the Union service, enlisted himself in spite of poor health and a family of six children, and was commissioned a brigadier general, U.S. volunteers. He took part in the West Virginia campaign of 1861, served in the Kanawha region and was in supreme command there from the spring of 1862 until August of that year when his troops were ordered to join Burnside's IX corps in Virginia. During Antietam, Cox commanded the corps, and at the close of the campaign (Oct. 6, 1862) he was appointed major general, U.S. volunteers, but the appointment was not confirmed. In April–December 1863 he was head of the department of Ohio. In 1864 he took part in the Atlanta campaign, as a corps commander.

As governor of Ohio in 1866–67, he advocated colonization of

the freedmen in a restricted area, sympathized with President Johnson's program of reconstruction and worked for a compromise between Johnson and his opponents. In 1868 he was chairman of the Republican national convention that nominated Grant. He was secretary of the interior in 1869–70; introduced the merit system in his department, and resigned in Oct. 1870 because of political pressure.

He took up legal practice in Cincinnati, became president of the Toledo and Wabash and Western railroad in 1873, and until 1877 was receiver of that company. In 1877–79 he was a representative in congress. From 1881 to 1897 he was dean of the Cincinnati Law school, and from 1885 to 1889 president of the University of Cincinnati. He died at Magnolia, Mass., on Aug. 8, 1900. A successful lawyer, and in his later years a prominent microscopist, he is best known as one of the great "civilian" generals of the Civil War. In 1874 he became military expert for the *Nation* and wrote extensively. Among his published works were *Atlanta* (1882) and *The March to the Sea, Franklin and Nashville* (1882), both in the "Campaigns of the Civil War Series"; *The Second Battle of Bull Run, as Connected with the Fitz-John Porter Case* (1882); and the valuable *Military Reminiscences of the Civil War* (1900), published posthumously.

**COX, JAMES MIDDLETON** (1870–1957), U.S. publisher, state governor and unsuccessful Democratic candidate for president, was born near Jacksonburg, O., on March 31, 1870. Leaving school at 16, he was a country schoolteacher for a few years before working in a printer's office. Later he became a reporter on the *Cincinnati Enquirer* and in 1898 bought the *Dayton News*. Eventually he purchased the *Dayton Journal Herald*, the *Miami (Fla.) News*, the *Springfield (O.) News*, the *Springfield (O.) Sun*, the *Atlanta (Ga.) Journal* and, in 1950, the *Atlanta (Ga.) Constitution*.

He served as congressman (1909–13) for the 3rd Ohio district (Dayton) and was governor of Ohio (1913–15 and 1917–21). During his terms as governor he introduced such notable reform measures as the workmen's compensation law, the provision of a minimum wage and a nine-hour day for women, the initiative and referendum and the establishment of a state tuberculosis hospital. He favoured the abolition of the federal inheritance tax, believing that the state alone should have jurisdiction over inheritances. Cox energetically suppressed violence in connection with strikes, his general policy being to hold local instead of state authorities responsible.

In 1920 the Democratic party nominated him for the presidency, with Franklin D. Roosevelt as his running mate. Cox was a strong supporter of Pres. Woodrow Wilson's policies and of the League of Nations, an issue that contributed to his defeat by Warren G. Harding, the Republican nominee. The electoral vote was 404 for Harding, 127 for Cox, with the popular vote being 16,152,200 for Harding and 9,147,353 for Cox.

He retired from political life until 1933, when President Roosevelt appointed him as a delegate to the World Monetary and Economic conference in London. In later life he operated a model scientific farm near Jacksonburg, O. Besides the ownership of several newspapers, he also owned radio and television stations. Cox died on July 15, 1957, in Dayton, O.

See *Journey Through My Years* (1946), an autobiography.

**COX, KENYON** (1856–1919), U.S. painter and critic, who achieved prominence through his murals and decorative work, was born at Warren, O., on Oct. 27, 1856, the son of Gen. Jacob Dolson Cox. He was a pupil of Carolus Duran and of J. L. Gérôme in Paris from 1877 to 1882, when he returned to New York, subsequently teaching with much success in the Art Students' league. Among the better-known examples of his work are the frieze for the courtroom of the appellate court, New York city, and decorations for the Walker Art gallery, Bowdoin college, Brunswick, Me., and for the capitol at St. Paul, Minn. He was the author of several books, generally against new movements in art and for what he termed "the classic point of view." Cox became a National academician in 1903, and in 1910 was awarded the medal of honour for mural painting by the Architectural league. Cox died in New York city on March 17, 1919.

His wife, Louise H. King (1865–1945), whom he married in 1892, also became a figure and portrait painter of note.

**COX, SIR PERCY** (1864–1937), British diplomat, remembered especially for his work in the foundation of modern Iraq, was born at Herongate, Essex, on Nov. 20, 1864. Educated at Harrow and the Royal Military college, Sandhurst, he joined the Cameronian regiment, then stationed in India, in 1884. In India Cox was posted to an Indian regiment and then joined the Indian political service. He gained varied experience, serving in princely states, learning languages and spending two years in Somaliland. The years 1896–1914 were passed almost entirely in Oman, the Persian gulf area and southwest Iran where Cox, showing great patience, sagacity and humanitarian interest, carried out some remarkable hinterland journeys. He dealt with the many local and international problems of a wide, lawless and ungoverned area and established cordial relations far and wide. He became a political resident in the Persian gulf, under the government of India, in 1909 and was knighted in 1911. As chief political officer to the Mesopotamia expeditionary force during World War I, Cox was responsible for all local relations in occupied Iraq. He was British minister to Teheran (1918–20) and negotiated an important (but never ratified) Anglo-Iranian agreement. Appointed high commissioner to the new state of Iraq, under British mandate, in 1920, he was deeply concerned with the establishment of the Iraqi monarchy, constitution and political life. The successful overcoming of many intractable initial difficulties was largely his work and that of King Faisal. Cox retired in 1923 and died while hunting near Bedford on Feb. 20, 1937.

See P. Graves, *Life of Sir Percy Cox* (1941).

(S. H. Lo.)

**COX, RICHARD** (c. 1500–1581), bishop of Ely and an active promoter of the Reformation in England, was born at Whaddon, Buckinghamshire, and educated at Eton and at King's college, Cambridge. He became a member of Cardinal Wolsey's new foundation at Oxford, being appointed first dean of Christ Church in 1547, and after holding various offices was installed as dean of Westminster in 1549. He had an important share in drawing up the 1549 and 1552 prayer books. As chancellor of the University of Oxford (1547–53) he encouraged foreign theologians such as Peter Martyr, and sought to remove all traces of Romanism from the books, manuscripts and ornaments of the university. On Mary's accession he was imprisoned for a short time, then released, and in May 1554 he escaped to the continent of Europe, eventually arriving at Frankfurt. Trouble there between the supporters of Cox and those of John Knox and William Whittingham, who had adopted an extremely puritanical form of service, ended with Knox's expulsion, and the 1552 prayer book was restored.

On Mary's death (1559) Cox returned to England, took part in the Westminster disputation with the Roman Catholics and was appointed bishop of Ely. He was intolerant and always anxious to constrain those who differed from him. While he refused to minister in the royal chapel, where crucifix and lights were retained, and was a bitter enemy to the Roman Catholics, he had little more patience with the Puritans. He was avaricious, and often came into conflict with courtiers who coveted episcopal lands. Elizabeth I intervened when he refused to grant his palace in Holborn to her favourite, Christopher Hatton, and Cox had to give way. In 1580 he resigned his see. He died on July 22, 1581.

See W. Whittingham, *A Brief Discourse of the Troubles at Frankfurt*, ed. by E. Arber (1908); C. H. Garrett, *The Marian Exiles* (1938).

(G. Hu.)

**COXEY'S ARMY**, a small group of about 100 disgruntled, unemployed persons who set out on foot from Massillon, O., March 25, 1894, for Washington, D.C. Led by Jacob S. Coxey, a self-made businessman, this "army" was the most famous of many such pilgrimages to the national capital in 1894 to popularize the need for economic reform. Sometimes referred to as the "Commonweal of Christ," Coxey's army favoured the Populist party program and the free coinage of silver. It successfully trekked across Ohio, Pennsylvania and Maryland, arriving in Washington on May 1, 1894. Now about 500 strong, the army peaceably descended on the capitol for the purpose of influencing congress to consider favourably two Coxey-sponsored bills—a good roads

bill and a noninterest-bearing bond bill. The latter called for the issuance by the treasury of \$500,000,000 in legal tender notes. This "petition in boots" ended ignominiously when Coxey and several of his followers were arrested for trespassing on public property. Shortly thereafter the whole industrial army movement collapsed as armies disbanded and enthusiasm waned.

See D. L. McMurry, *Coxey's Army* (1929).

(R. K. M.)

**COYOTE**, a North American member of the dog family (Canidae), also known as the prairie wolf, *Canis latrans*. Ranging from Alaska in the north to Costa Rica in the south and frequenting almost every kind of country, especially the plains, the coyote is smaller than the wolf and more jackal-like (usually under 30 lb in weight). The over-all length of about 36 in. includes 12 to 15 in. of tail. The general colour is grizzled buff above and whitish below; the legs, reddish. The bushy tail, directed downward when the coyote runs, has a black tip and a dark gland patch near the root. There is, however, considerable local variation in size and colour as seen in the many subspecies.

Although coyotes are slinking and stealthy nocturnal hunters, they often attain a speed of 40 m.p.h. in their pursuit of fast game, which they frequently run down in relays. Their attacks on domestic animals have been greatly overrated. Hares, chipmunks and mice form a large portion of their food; but also eaten are the fawns of deer and prongbuck and sage hens and other game birds. A surprising amount of vegetable food is also taken, including the fruit of prickly pear cactus, rose hips and juniper berries. Coyotes dig burrows for themselves, usually on a slope, or take possession of those already made by badgers and prairie dogs. There, in the spring, the half-dozen or more coyote pups are born. The parents, lifelong mates (life span about 13 years), are attentive and solicitous, feeding and teaching the young until fall. The coyote, alone or in company, performs a regular nocturnal ritual—his distinctive serenade, consisting of short yaps, whines and barks to mournful howls. See CARNIVORE.

(J. E. H.; X.)

**COYPEL**, the name of a French family of painters who executed many of the large historical compositions that decorated the royal palaces of France. NOEL COYPEL (1628–1707), also called from the fact that he was much influenced by Poussin, COYPEL LE POUSSIN, was employed by Charles Errard to paint some pictures required for the Louvre. In 1672 he was appointed director of the French Academy at Rome. After four years he returned to France; and not long after he became director of the Academy of Painting. The "Martyrdom of St. James" in Notre Dame is perhaps his finest work.

His son and pupil, ANTOINE COYPEL (1661–1722), was more celebrated than his father, with whom he spent four years at Rome. At the age of 18 he was admitted into the Academy of Painting, of which he became professor and rector in 1707, and director in 1714. In 1716 he was appointed king's painter, and he was ennobled in 1717. He was a clever etcher and engraved several of his own works. His *Discours prononcés dans les conférences de l'Académie royale de Peinture*, etc., appeared in 1741.

Antoine's half-brother, NOEL NICHOLAS COYPEL (1692–1734), was also an exceedingly popular artist; and Antoine's son, CHARLES ANTOINE COYPEL (1694–1752), was painter to the king and director of the Academy of Painting.

**COYPU**, a large South American aquatic rodent whose reddish-brown fur is of some commercial value and is known as nutria. See NUTRIA.

**COYSEVOX, ANTOINE** (1640–1720), French sculptor of Spanish descent, best known for his portrait busts and his decorative work at the palace of Versailles, was born at Lyons on Sept. 29, 1640. He came to Paris in 1657 and studied under L. Lebert. He was made sculptor to the king in 1666. By 1679 he was at Versailles, where he contributed to the decoration of the

COYOTE (CANIS LATRANS)

Galerie des Glaces, Ambassadors' staircase and the Salon de la Guerre, for which he carved the brilliant equestrian relief of Louis XIV (c. 1688).

Coysevox executed much decorative sculpture for the royal gardens, notably the equestrian "Renown" and "Mercury" at Marly (1700-02). His work also includes a number of important tombs, notably those of Colbert (1685-87) and Mazarin (1689-93) and the great votive group of Louis XIV on the high altar of Notre Dame. These, like his formal portrait busts of the king and state dignitaries, are of a far more baroque character than the work of any of the great sculptors working at Versailles. But in the more intimate of his magnificent series of portrait sculptures, such as the statue of the duchesse de Bourgogne as Diana (1710), he drops the Berninesque swagger and formality of his state portraits and anticipates the naturalism and grace of the rococo style. His principal pupils were his nephews Nicolas and Guillaume Coustou and the elder Lemoyne. Through these three sculptors his influence extended almost through the 18th century. He died in Paris on Oct. 10, 1720.

See G. Keller-Dorian, *Antoine Coysevox*, 2 vol (1920); Luc-Benoist, *Antoine Coysevox* (1930). (F. J. B. W.)

**COZENS, ALEXANDER and JOHN ROBERT**, English draftsmen and painters of landscape in water colours.
